- These groups do have disadvantages: they have a limited network in the territory, it may be impossible to benefit from significant gains that the parent bank may be experiencing at home, a limited knowledge of the economic environment and how customer segments react.

Competition between the three groups manifested by applying differentiation strategies takes into account issues such as: interest rate, geographic location to the services (territorial network), the fees and

charges levied for such services, and the speed and safety of services.

In regards to the interest rates for deposits and loans received, a competition was conducted between banks that are part of the first two groups (Table 4).

Table 4. Differing elements of banking products and services

Differing elements of banking products and services	The group of state-owned banks	The group of private banks	The group of branches of foreign banks
Interest rates	X	X	-
Geographical proximity to the clients	X	X	-
Fees and charges	X	X	-
The speed and safety of products and services	X	X	X

Source: author's data

Superior management representatives of several credit institutions believe that the future of national banking market can be influenced by the following success factors[4]:

- rapid and effective resolution of customers' needs;
- offer a wide variety of personalized quality banking products and services;
- reduce time to resolve problems reported by customers.

Given recent developments in the banking environment, for any credit institution, factors such as: diversification, innovation and customization of products and banking services should be a priority.

In a consumer society where time has become a "commodity" more and more expensive - time is money, and urban traffic congestion is already a daily reality, the best solution seems to be frequent use of

electronic distribution systems of banking products (cards), the computerized machines (ATMs and terminals for electronic funds transfer at point of sale) and electronic banking system that virtually places customers in the banking institution (services such as Internet banking, mobile banking, home- banking).

According to the international standards in order to be considered truly modern banks, the Romanian banking institutions are required to submit a strategic program, and therefore within the major commercial banks there were set up departments of strategy that deal with the elaboration and implementation of strategic programs.

Abstract

Despite the complexity, the ambiguities and even the contradictions of the concepts of "personal development" and "types of training for personal development" that are shown in our early researches, we continued to study the relationship between the two concepts and attempt to identify the issues that could form the basis for debates on the legitimacy of "personal development". In other words, we believe that if the terms refer to different concepts and practices, confusing, even contradictory, however they are not meaningless.

Key words: management, public institution, personal development, training, professional development

J.E.L. classification: H10.

1. Introduction

In an organization, the concept of "training for personal development" seems unfair and seems to concern especially leaders and managers. There would be differences between what could legitimately be expected from such actions if we refer to their theoretical references, and what is actually done.

In general, personal development training includes training focused on the individual, that means a type of training focused on a better understanding of self, of the relationship with others, that suggests a better understanding of the interactions between individuals.

2. Fundamental aspects of personal development

2.1. The concept of personal development

For practitioners, and researchers 'personal development', although strongly present in the speeches and writings, seems to "slip through their fingers" as soon as they try to understand it more precisely. It is so difficult to find a clear definition. The trend is rather to take into consideration as many experiences and as many definitions as there were analyzed, in what concerns the experience of "personal development". However we found two definitions for this stage of our research - the subject of our paper itself is to clarify them or make them evolve:

1. "Personal development is based on the development of capacities in the field of self-knowledge, the mastery of relational savoir-faire and in the field of behaviors. The emotional involvement and emotional conduct of this research requires a satisfactory framework: a competent trainer, outside the enterprise, respect for values, for the personality of individuals. In addition, any personal development must be able to be clearly explicit in connection to its theoretical references, its methods and its code of values. It must also respect the person and its physical and mental integrity." [1].

2. "Everyone agrees, to talk about personal development is to speak about individual growth in all its aspects (physiological, intellectual, emotional, relational, spiritual ...). (...) Each person would tend to orient in specific directions that C. Rogers describes as "positive,

constructive ... they tend to go towards self-actualization ... progresses towards maturity and socialization."(...)

We thus note the following three dimensions, all of which incorporate the notion of personal development:

- Development of general intellectual skills (construction of knowledge, logical reasoning, analysis and synthesis capabilities ...)

- Personal development at an interpersonal (ability to express, to communicate, to manage their emotions ...)

- Personal development in terms of evolution of the individual (ability to orient themselves, to manage their career, develop their professional potential, to make choices ...).

Generally, "personal development" could be summarized to a second dimensions: "personal development" at an interpersonal level.

Thus, GARF (groupement des animateurs et responsables de formation en entreprise = the group of trainers responsible with training in organizations) had adopted in 1995, in their statistical tables about business training, two training specificities for "personal development":

- The development of behavioral and relational capacities: emotional control, stress management, developing the ability to speak, to communicate, to assert .

- Development of the individual capacity of organization: personal organization of the working time, organization of effective teamwork.

2.2. Specific types of training objectives inventoried in the domain of "personal development"

- To easily win the trust and to have the capacity to relate

- To exercise your authority using diplomacy

- To build successful scenarios

- To excel in relationships and communication

- To be able to mobilize your own personal resources and those of others

- To know how to act and communicate in different situations

- To strengthen the collaboration

- Fostering relationships of trust

- To overcome rigid behavior

- To create dynamic relationships

- To develop your impact on different actors in the organization.

- To raise the responsibility of staff

- To create a climate of confidence around you

- To promote adhesion on projects

- To be able to adapt to your interlocutors

- To formulate your arguments in order to convince

- To you know your capabilities better

- To obtain operational solutions

- To develop starting with the resources you currently have

- To manage the stress of ambiguity and change

- To balance between the demands of work and personal life

- To be creative in order to make decisions

- To increase your ability to concentrate

- To develop your inner resources in order to use them in difficult times

- To get an idea about yourself on long term

- To optimize the management of stress, health and your relationships

- To better manage your assets

- To approach this new life (retirement) with inner peace and with projects, etc.

3. Characteristics of the management process in public institutions

3.1. The concept of public management

Being under the influence of uncontrollable factors and based on legal procedures relatively differentiated, the public sector, across time, was a main focus of theorists. Thus, Ranson and Stewart [7] state that "the challenge is to discover the new era of moral and political principles which correspond to transformations suffered by the public sector."

This challenge is even more pronounced as the boundary between public and private is neither clear nor permanent [3].

Public management is a complex discipline, which calls for a much broader field than disciplinary businesses. The two areas share the science of management: the organizational management, the complex dynamic systems, technology and innovation management. In addition, public management

goes beyond these disciplines, integrating approaches to understanding the evolution of society [4].

Many variables and relative definitions of the concept of public management resulting primarily from the complexity of the public sphere appeared, these definitions are subject to a double causality: on one hand, the public area is faced with the multiplicity of territories and institutional partners. On the other hand, we witness the increasing need for public services, for beneficiaries with different horizons. Consequently, the multiplication of specific occupations within the public sphere and public transparency of dialogue between the actors can meet these requirements, but subject to a proper legislative context.

The issue of the complexity of the public sphere can not be raised without emphasizing the political influence, namely the vulnerability of national political systems [2].

Another factor lies in the complexity of the public's sector need to act in a strictly financial context.

A study [6] states that public management is an "institutional myth", meaning that it refers to the gap between the rigorous image that the public organizations tend to project on the adoption of structures/systems that are perceived as legitimate, and on the other hand translating these into practice.

The stake in public management is not managing all aspects of the public sphere but to use efficiently and effectively specific management tools and techniques. Trying to control and master everything is not only expensive but also illusory.

If in some areas, more technical, every action leads to an outcome necessarily rational, even mathematical, in the public sphere a lot of energy can be spent without the result becoming visible. In other words the gentle alchemy that has to be put into action in the public sphere, leads to a quasi - uncertain outcome.

This phenomenon is amplified by the poor wording / the insufficiently clear goals of a government program or initiative, but also by the fact that the actors involved have different purposes, different perceptions and strategies.

In our view, public management can be defined by a three-dimensional approach: the first dimension is the efficient and effective use of all categories of resources in implementing the policy, the second dimension of public policies are aimed at increasing performance and suitability for the needs of the beneficiaries, the third dimension is to create a space for reflection and action by public actors, allowing them to engage in building a consensual approach. Public management should be turned into a commitment to change and maintain a balance of change.

3.2. The process of management in public institutions

In an open understanding, management focuses on two broad objectives: piloting the organization in the sense of decreasing environmental turbulence; reduce wastage resulting from internal disturbances.

Management consists in using rigorous approaches at all levels of an organization to avoid entropy. The evolution of management in public institutions is based on four major challenges: the structural challenge, the decisional challenge, the challenge of implementing effective and practical animation of the actors.

The structural challenge consists in the need to meet a double need: the rigidity of traditional systems and procedures and the dilution of the roles of specific organizations, as a result of mismanagement.

It results that management must address the current phenomenon of techno-bureaucracy in public institutions. This objective appears to be necessary even in decentralized structures, which sometimes face rigid new behaviors.

3.3. Quality and performance in public institutions

The importance of quality in any business is based on several findings:

- quality is a relative concept, and even the positioning based on a range of products has a certain quality logic, according to clearly defined criteria;

- non-quality is often much more expensive than the quality itself, since it is based on a set of socio-organizational failures that generate loss of resources;

- quality is a source of credibility for the client, contributing to the competitiveness of organizations.

These findings are also applicable to public sectors, sometimes in a more pronounced way, because the stakes for quality is to increase the level of trust in public authorities, which points to more political constraints.

This quality is one of the possible public-sector responses to environmental changes such as increased demands and users.

However there are fundamental differences in the quality of private and public sectors that results from the particularities of the customer.

There is a major difficulty in the study of the performance of the public sector: on the one hand the weight and complexity of the bureaucratic system that does not allow global changes, on the other hand the action in the midst of a system may cause cascading effects on other dimensions of the public sphere.

Tackling with the issue of the public sector's performance can be subject to a multitude of possible logics. The three main logics could be [5]

- The logic of the engineer who aims for the development of the intrinsic productivity;

- The logic of the economist, which seeks to minimize costs and increase consumer satisfaction

- The logic of the politician, that seeks to observe the impact on the consumer.

If the engineer and the economist's logic can exist in both public and private sectors, their combination confers specificity and complexity of the political concept of performance in public institutions.

4. Personal development from the perspective of the management of public institutions

4.1. Personal or professional development?

Analyzed and often viewed as a whole, particularly in French literature, the professional and personal development must be analyzed separately. Professional development is only one aspect of personal development, which relates exclusively to the development of the occupational role, while individual development includes all aspects of personal development, referring to the uniform and complete development of human personality.

Personal development is a part of the management. In France, as in Anglo-Saxon countries, but with a delay of several years, most enterprises have embraced this new strategic situation.

But for some people, performing or supporting "personal development" in the enterprise to integrate further vocational training, induces an evolution from the "personal development" to the "professional" one.

For some supporters of transactional analysis as well: "the idea of personal development training is difficult to reconcile with the very essence of personal development approach in the sense of self, individually, from a felt need, and then identified. Such an approach allows access to himself, to his design, his wish, regardless of interference with other projects. "

Eventually it would not be so much about "personal development" but about "professional development".

In an organization, this new strategic situation concerns mainly professionals, leaders and managers.

4.2. Personal development as a strategy

Given that the provision of personal development is now a billion pounds industry, is there any reason as for personal development strategy to be adopted as a training and development? One view is that it can not be avoided. In a rapidly changing world, an uncertain world where flexibility, adaptability and learning new skills are the

name of the game, individuals have no choice but to assume greater responsibility for developing and measuring their chances of employment.

In terms of resources, a convincing argument in support of personal development is that it can be related to training for a specific profession (job-related training) - "to work" in the sense of supporting it, making it more complete and more sustainable. The argument is that the training that focuses on skills and behavior is mostly a transplant operation. It may introduce new material, but there is too little time for this material to become rooted in the deeper soil of beliefs and values of the employee or his image of himself or his models about the world.

Organizations that seek to provoke thinking, attitudes and values of their employees must do more than hire people from a professional perspective, they must engage its employees in terms of personnel at all relevant levels. Here, the options are as follows:

1. to ensure that all training events have a dimension of personal development.
2. to give way to personal development before or simultaneously with the formation.
3. A third option is mentoring (tutoring) and/or face to face training (one-to-one coaching) The latter is currently in vogue, especially among managers who have the means to hire external consultants for personal development - budding occupational group currently extremely rich people who have basic training in neuro-linguistic programming and sport psychology/ training development (coaching). Attitudes towards support mentoring as a way for personal development varies from one organization to another. It is embraced, for example, in many companies and most state schools in Britain, in part because it is seen as a means of promoting personal development of both mentors and their public, but other important commercial organizations are avoiding it stating it is an outdated culture (eg Microsoft). The forms of DIY (Do It Yourself - Do it yourself) could represent the future.

5. Tips for personal development

The following points are indicators as being of good practice in providing personal development.

1. Try to obtain congruence. The organizations supporting personal development must ensure that their policy and practice is more consonant with the spirit of personal development.

2. Try to provide professional development opportunities for both individual (personalized) and for broader personal development.

3. Clarify who owns personal development plans and portfolios. Typically, the organization has a more legitimate stake in the plans that focus on professional development needs and intentions than those who are really more of a personal nature.

4. Usually, do not relate opportunities to participate in personal development trainings offered by the enterprise. As an opportunity offered and accepted as a gift ("something for me"), providing personal development is less likely to be rejected and more likely to be received positively.

5. Let anyone that has a function of development or works in human resources management to develop "relevant pro personal competence" - eg the ability to appreciate the personal development needs that support professional practice.

6. Encourage a proactive approach to career and personal development. There is the need to be an ongoing concern rather than a reaction to a "crisis" (restructuring, too many employees, etc.).

7. Encourage employees to see themselves as "self employed" and see the organization as being their best customer.

8. The following points show the quality of personal development programs:

- Tendency to limit the number of participants to facilitate a full interaction with the participant (although the group scale events can yield results, especially at an emotional and motivational level)

- Tendency to have a generous proportion of trainers for participants so that the latter receive a one-on-one guidance (in front) when needed;

- Looking to work on personal development in general, and on explicit course objectives;

- Tendency to include time for personal reflection, and for interaction and exercises.

9. Fill libraries and resource centers for employees with the broadest possible range of books on personal development, tape recordings, CDs and other materials.

6. Conclusions

One of the main reasons that continuous education and professional development is likely to fail, is probably the fact that the institutions lack a pattern of systematic training or personal development. If the main purpose of education is to contribute to the overall objectives of the organization, the main purpose of a model of institutional learning is to develop professional and public officials, to prepare them to become people who learn continuously (lifelong learners).

Systemic Perspective of Communication - Business Development Premises in the Context of Global Crisis

Popescu Manoela

Crenicean Luminița Cecilia

"Dimitrie Cantemir" Christian University of Bucharest,

Faculty of Commerce and Tourism Management

manoela.popescu@yahoo.com

lumi_cecilia@yahoo.com

Abstract

Systemic approach to communication concerns that it could be captured in its dynamic, under the influence of its determining components, with a complexity greater than its component parts. In this sense, communication is considered an open system, being influenced by the context in which it appears and develops, but also the dynamics of its component parts. The synergy created thereby contributing to the effective operation and business development.

Essential is considering the communication both the trial and phenomenon, but especially, as a link between demonstrating the relationship which ensure high performance at the organizational level and national level.

Key words: system, communication, business, structure, function.

J.E.L. classification: D1, D83, D85, O1, P0

1. Introduction

Cognitive complexity, emotional and behavioral communication can be addressed only scientific and practical effect only in *systemic* perspective. Systemic theories concern Cybernetics (Wiener, Cybernetics or Control and Communication in the Animal and the Machine in 1948), organization (Morin, La methode.1. La nature de la nature, 1977) and constructivism (Foerster) provides points of considering communication as a premise for starting in business development. Obviously, business development, helping to increase the valued of the various components of the

communication process (communication means). Also, the type of interaction between communicators parties increases and / or appear other types of relationships (interactions) with repercussions on business efficiency.

Business - profitable organization - is the major institution of key economic sphere and its role is to produce goods and services necessary to maintain a certain standard in society. Although the business (profitable organization) is a system that does not mean that the organization is the only place or principal place of communication. Arguably, at the organizational level, cultural context influence the process of communication and support external communication, and the one who is articulate and manifest within it (socio-professional communication, group communication, local communication, for companies with branches in many areas, communication or communication department compartment level).

Business Communication is an open system based on the concept of interdependence, subsystem, equitable-purpose, multiple-purpose, structure, processes, and the premises is an informational filter "color" components of the process communication.

2. Systemic communication approach - between reality and objective necessity in the context of economic crisis

Communication system approach not only tries to make sense of action within the organization or provide all important communication to coordinate its components in a precise meaning, but to exploit and

capitalize elements of communication process, uncovering interdependencies and internal connections communication, generating synergies and complex structures needed for business development in the current context. Also, cognitive and practical approach that takes into account the communication as a subsystem of the business (profitable organization) and manage effectively generated on the one hand influences the socio-economic formation that manifested itself, and on the other hand, the existence of national communicators, which determines the content and forms of communication.

The economic crisis is a crisis of communication in business and systemic perspective of communication is essential in overcoming it, especially since there are concerns about crisis communication. But whatever the context, systemic approach to communication is a primary means of business development as contributing to the development of communication personalities (staff and economic entities).

2.1. Communication structure and functionality

Known is that any communication behavior has a great cultural value. From this perspective, communication is a system of meanings and symbols created by human thought, whose diversity results from changes occurred during individual events. There should not be omitted the class character of any system of symbols, the relations between social systems and the forces holding symbols of power, technological nature of the system of symbols, etc. The output from the communication system is the conversion of human behavior. Therefore, one can say that the business organization, communication emerges as a subsystem of the business that is open. In this case, correlating communication subsystem with the other subsystems is very important in order to identify the influences exerted by the on the work of the organization.

Spheres of communication are a matter of morphology or anatomy of communication. Through their intercession may be understood internal processes of diversification of communication as a result

of historical development in time of the organization. Indicating and analyzing every sphere of communication and their relationship to identify and delineate the structure of communication that is relative to the type of organization. Communication systems are of great diversity in time and space relative to the many human groups and ways of combining elements of communication process.

So we can talk about a basic level of business communication, but the level is not homogeneous, it is composed of several distinct units called communicational spheres. As the levels increase to the peak of organization, communication spheres begin to be homogeneous.

Spheres of communication, as an expression of a minimal variety of communication media, are also basic communication functions such as position information, socialization, advocacy culture, integration, motivation, etc. As a characteristic type of business, each sphere is undergoing a process of internal differentiation and specialization. This process can be analyzed by morphology of the spheres. A separation of these spheres of communication is difficult but not impossible, and could speak of the sphere or *members of the sub system-culture of the organization, science sphere, language area or subsystem sphere, or ethical subsystem*[6].

Morphology of communication involves a process of differentiation of types, genera and species of various elements of the communication process. At the organizational level there is a different kind of process, namely the integration of various elements of communication in an organization's communication structure. Typically, this integration is pursued in developing a strong communications within that organization. As a result, areas of organizational communication can be searched in two ways: as research specific areas of human groups, that research integrating social legislation of a sphere of action of the communication structure of an organization.

Culture members of business organizations is translated into manifestations in action, the participation in events, feelings, *the creation as a form of labor in general, affecting the life and work collectively with*

serious consequences and can even transform business. In this regard, creation plays a decisive role, and communication is essential in the act of creation. When researching the creation-action as a form of thinking of how an individual is considering the following issues: social background of the individual, spiritual and material dependence of the ruling class, or one that represents social position, economic situation, prestige, studies, etc..

The analysis of science sphere involves examining organization, planning, management and administration theoretical and practical knowledge, efficient use and personality of those who possess this knowledge, their typology (professional categories structure age, sex structure, occupational mobility, etc.), their overall motivation of applying theoretical knowledge of the working structure of individuals, age in relation to the type of activity, the combination of theoretical knowledge in relation to the activities implemented in practice. It is also necessary to know the degree of cohesion, competition between members of the business, and specialization within its existing relationship between the body of knowledge and results, the social climate of the organization of groups, individuals and corporate social responsibility organization. One should not forget to analysis the social functions of the combination of knowledge, knowledge that all the factors of production, assembly and integration of knowledge production. It should be noted also that the dynamics of various sciences contribute greatly to the increasing complexity of different knowledge in different fields. In such a context, this important sphere of communication, it is a series of functions[3], such as cognitive function, regulatory function, practical function - transforming creative function etc. Under these conditions, it should be mentioned that all members of an organization's knowledge is influenced and determined by: the development of the society in which that organization operates, the degree of specialization of the work of the organization, the degree of development sciences and forms of education in that country in which the organization operates, the social, political, cultural organization, the language used by the organization, existing

training system in the country, family, group of friends of each member of the organization, the degree of interests of members and the organization, social class in which each member of the organization, the degree of membership of each member of the organization, the value system of each member and the organization, religion, etc. organization members.

For its part, science has many influences on: the work of the organization, the language used by an organization; spheres of communication in business environment in which the organization operates, results generally members of labor, religious members; efficiency of the organization, rules, regulations, laws, organization, attitudes and beliefs of its members; values (value system) organization, thinking of organization members, etc..

The set of knowledge held by an organization (by members of an organization) influences and is influenced by the language used by members of the organization[3]. Each domain of knowledge operates with concepts, categories and laws developed inductive or deductive, rational level. Thus, in any organization there are two types of language: scientific and common[2].

Language is an integral part of social activities, he articulating practices, guidelines and human relations in a particular life situation. In business, messages reach individuals situated in a relational context previously determined by the membership and reference groups. The reference group performs a normative and a comparative basis, taking an active role in receiving messages in the selection and understanding the meaning of meanings given to[1]. There is a direct connection between the position of the organizational structure of each member of the organization perceives the message and its image.

In contemporary society, information has become an essential component of the human condition, an important means of knowledge. It is indispensable for the organization and business development, degree of organization depends directly proportional to the amount of information stored in these organizations. **The means of communication are consisting as important resource in development**, information provided by them

being an effective way to reduce uncertainty socio-economic processes.

2.2. The place and importance of communication in all social structures and business processes

Communication is a social phenomenon with a specific character, the reality of the communication process cannot be conceived outside the office. First, because both, the transmitter and receiver are men, bearers of culture. Man is a social product, in essence, being a social being. As such, he creates culture, expressing the ideals; aspirations, confronted by his work with the wishes of other people, and are developed through relationships with other person, that is through communication[5]. Communication is really a social variable. If any communicational reality is also a social reality, it can be said that all social reality is both time and communication phenomenon? Given the complexity and the level at which it was currently exploring the phenomenon of communication, the answer is relatively clear.

It should be noted that any process of communication requires the establishment of premises as two elements: objective reality (inside and outside the organization) and the human subject. Man enters into the objective world in accordance with nature's own, on a spiritual level, but it must transform the environment, not by its mere presence, but through knowledge. On the origin of any act of human communication is dissatisfaction with the situation found by a goal and aspiration towards an ideal toward which the change existent. Certainly, the situation is not only found the objective reality, but is a function of culture, because the existing objective and impersonal viewed from the perspective of human socio-cultural, subjective.

Business organization is a social space, communication is continuous reality creation occurs social reality is a socio-communicational (according to school in Palo Alto). A new paradigm of communication highlights the crucial importance of context in determining the characteristics of the communication process. Along with human nature, *communication is*

the key factor that creates and develops the personality and significance.

In order to define elements that may identify the coordinates communication across organizational structures and social processes, communication could be defined and analyzed through guidelines: structure-functional, actionable (model formulated by Jurgen Habermas - Communication and Action, representing the latest generation of the Frankfurt School), structuralism and phenomenology (model formulated by the Palo Alto school based on the integrated consideration of communication as a social phenomenon).

The social system of the business is a multitude of individual actors (individuals), interacting each other in certain situations. The office is in their view a specific analytical concept which allows knowledge interdependencies, how to integrate the parties, the nature of interdependence, the social regularity, etc. The system components are connected in functional complex, and the type of connection between components is one of functional dependence. In these circumstances, a *certain communication increases the creative forces of the individual Communication is the human capacity in the service of growth, the active creative forces of man, becoming a force*, because it contributes directly to business development, and that *allows individuals to adapt to the social life of the organization by buying and mental characteristics habits.*

Structure-functional as models of objective and holistic analysis of social reality are projections of epistemic relations and social space in which social facts, since they are shaped and motivated axiological are material[6]. Thus, the means of labor within the social organization not covered due to their physical, chemical, technical, etc., because in fact they express work relationships. All these relationships that make up a given social system's own structure, by fleshing out the specific mechanism of its development, are determined and influenced by communication.

Social action cannot be reduced to the analysis of the actor in terms of role and social status, which are given in the system because, in reality, the individual is able to transform the roles and statuses the system

itself, transforming social relations system. Note that an actionable analysis of communication focuses on the *analysis of the action and interaction contexts associated with language and symbolic exchanges*. Interaction between the individual, organization and culture leads to the formation of behavior patterns that provide the organization: structure, organization and cohesion.

Social relations have a characteristic that is they are average. This feature means that the interpersonal relationships involved in the diversity of traits consistent and repeatable ways of social relations. As average, social relationship is a normative relationship, it involves a pattern which standardize behavioral reactions of some individuals being in social relations.

Communication is a complex phenomenon, dependent on the society in which business occurs. Moreover, communication is a tool works, through an exchange of information. Addressing the communication as a term that expresses man's relationship with the world, says the idea that the phenomenon, instrument, understanding provide rules for everything in the world, as science, ethics, art, practices are only subsystems of the communication system.

In this context, as a system with a given social structure, organization structure affects communication, that it takes a configuration dependent group structure, community, working, etc. operated.

3. Implications of the systemic communication perspective over the business growth

Regardless of how privileged manifestation of the interaction between the firm and the environment, provides communication support scientific, theoretical and practical to provide a high efficiency by undertaking activities, by generating a communications culture in which all organizational members have market awareness, product and the company.

The dynamic environment in which firms operate they hardly find proper ways of action that a proactive role to assume. In this respect, it is clear that companies have three options with regard to attempts to generate

changes in the desired environment for them, namely: adaptation to the requirements of the environmental features of the company, trying to influence business-friendly elements of the environment, diversification horizontal activity and / or vertical based on the existence of clusters, networks of companies or partnerships.

All these options can be undertaken successfully if the firms take into account *community and communication skills*[5]. At the same time, successful completion of products / services and business process is a direct result of people involved: employees, suppliers, customers, funders, intermediaries, counselors, etc., *culture and information carrier*, and *various communication capabilities*. The companies that help in identifying and generating change by giving them the necessary support and understanding of organizational development is communication.

Is a reality that communication is seen as the most important form of human interaction. But if it starts from the notion that the company is the people who compose it, we can say that one of the most important manifestations of the interactions between the firm and its environment action is communication. Thus, inside the company is developing a specific subsystem, the communicational one, which manifests itself as a self-system.

Known is that the competitive firm has a synergy of its components necessary to achieve performance in a highly competitive context. Communication is one that ensures that invisible thread that unites people and which determines its synergistic explosion. But it is vital that communication within the company to be effective.

Each firm is characterized by a different communication behavior since the communication entity bears the influence of personality is firm. Thus, as an individual communicates with his entire life experience, by virtue of his personality, interact with the environment in which the company operates under the imprint of its cultural uniqueness. Peculiarities of communicative behavior may occur are the result of the influence of internal and external business factors that are nothing more than factors of influence organizational culture.

Based on the logic of a systemic process and very complex phenomenon, it becomes an important element of communication, supporting its effects. In systemic approach communication directs developmental models of the principal element of the communication process: the entity (individual, business).

4. Conclusion

Regardless of the models used in communication or communication approach as a process phenomenon is significant social relationship established between communication partners. Developed by the semiotics school, structural models of communication bring to the fore the systemic perspective of communication as a requirement for the development entities. The communication is developing not only individual persons but also economic and social entities, regardless of the context in which it occurs, although the influence of that context supports. In other words, the crisis, taking into account the spheres of communication and synergy elements of communication process generates an effective tool for business development.

Considerations on the Rationale and Approach of Decision Science

Popescu Oana Catalina
Academy of Economic Studies, Bucharest

Abstract

The approach to decision theory has varied from one scholar and school of thought to the other from the development of mathematically complex systems, models and equations to the disregard of this particular academic endeavor altogether due to randomness and overwhelming subjectivity and complexity.

This paper shall briefly cite the main opposing perspectives on the general decision-making model, and in so doing argue whether the study of decisions makes academic sense at all. Concluding as to not only the pertinence, but the necessity of decision science, we do however admit the need for a more comprehensive and integrated approach.

We then attempt to draw the guidelines of a general decision model, and later list some of the factors that such a model should integrate in order to constitute a realistic point of reference.

Key words: decision theory, decisions, game theory, economic modelling

J.E.L. classification: C18, C51, C70, D70, D80, D90

1. Introduction

If our proudly-affirmed factor differentiating and ultimately defining the human species is the development of conscience, then the most powerful manifestations of the said conscience is decision-making. Existentialism – determinism debate apart, people's actions are driven by deliberate choice in a manner that shapes the future state of themselves, those around them and the environment. It is therefore not only highly interesting, but also prudent and responsible to research the way in which people fundament and pursue their

decisions. People in the marketing industry have understood and implemented this quite well. Psychoanalysis apart as well, the better we understand what drives us and our cognitive functions to function the way we do, the more control we will have over ourselves and the effect we have on our environment (by environment here we mean not only natural habitat, but social, organizational, etc.). In the words of two of the most prominent figures in decision research, "in making decisions, you may be at the mercy of your mind's strange workings". Since von Neumann and Morgenstern's (1947) and Savage's (1954) first attempts to formulate a set of axioms that frame the decision-making process, decision and game theory have well-established themselves as self-standing fields of study with a significant degree of applicability, relevance and impact. The better-known and somewhat more popular discipline of management science, organically linked to decision and game theory, brings a vast literature and a great number of case studies and real-life examples to the cause. Beyond what Raiffa envisioned as "decision science", virtually every field of research concerned in the least with human thought or action has an input to bring to the interpreting and understanding of decision-making: from statistics to ethics and psychology to history and biology, and the list could continue. What now constitutes a great effort is to accommodate the different views, perspectives and angles on the different constituent details of decision-making into a great comprehensive and integrated theory.

Looking into the vast literature on the way people do and should make decisions and all the factors that interfere with this process, at least three broad basic questions stand out: Is it relevant to pursue the study of decision-making at all? What is the general framework for the decision-making process? and Which

disruptive factors interfere with this process?

2. On the relevance of pursuing the study of decision-making at all

This debate is one of coherent versus chaotic approaches to decision-making.

One extreme, disjoint incrementalism [1] proposes three guidelines:

- In taking a decision one should only consider those policies which present marginal differences one from another.
- The known or expected consequences of these policies should present only marginal differences from the status quo.
- Policy comparison should be led by comparing only those marginal differences among policies, and not by comparing entire „social states”.

The implications of this approach involve the review the classical framework for social welfare: the reference is no longer the general optimum, but rather the status quo. Marginal differences are the only ones pursued not because of their ability to lead to the optimum, but because a deeper investigation would be impossible or otherwise unwise. However, disjoint incrementalism shouldn't be considered a form of conservatism; even though a „revolutionary” change is excluded because of too far-reaching and unpredictable consequences, a succession of marginal changes still preserve the whole capacity of adding up to a major change. On the other hand, practice provides numerous cases in which alternatives differ among themselves by numerous aspects; sometimes an alternative favored by one criterion is regarded far less favorably by another. This observation contradicts the theory of marginal variations of alternatives. Secondly, certain decisions, such as strategic decisions inside companies, may suppose fundamental changes, with vast repercussions, thus also contradicting the marginal variation from the status quo. Finally, comparing alternatives at a detail or criterion level presents the disadvantage of capturing only in part the relative importance of criteria, while in the same time inhibiting decision-makers from forming and assuming an overview understanding, involving both advantages and disadvantages. Disjoint incrementalism

is well suited in return to be applied to the successive detailed steps needed in implementing a large-scale policy. In this case, following marginal differences presents the advantage of ensuring the coherence of actions as they unfold and the approach of each element „in due time” and with full attention. Disjoint incrementalism would therefore form a useful tool in implementing large-scale decisions rather than a conditioning of decision in general.

At the other extreme, inside “garbage cans” solutions are generated prior to problems and are attached to problems in a seemingly random manner [2]. This chaotic paradigm would be especially characteristic to large and bureaucratic organizations as a result of over-procedurisation. If this were so, then such organizations would be not only inefficient, but their very survival on the competitive market would similarly be a matter of hazard. Otherwise stated, if no decision is fundamented and no decision is duly carried out then the organization can only progress towards chaos and nonsense until the point where it is no longer adapted to cope with its market environment and acts like the organizational equivalent of a “mad man”. Therefore, although it is obviously the case that in some organizations bureaucracy and imposed procedures hinder some lean decision-making processes, decision-making, though admittedly delayed and with numerous approvals, does occur and is indeed enforced. What's more, such procedures and bureaucracy were originally adopted as a system for risk prevention and should be considered as an integrated part of decision-making in this particular environment. The whole discussion is however framed by the distinction between individual or personal decision-making and organizational or group decision-making. The first process stops once the decision-maker has reached a choice of action. The second process, on the contrary, is barely triggered by the individual preferences, stakes involved and relationships or degrees of authority of all stakeholders involved; what follows is negotiation and/or consecutive approval in a recursive process in which one person may review his/ her original stance several times in relation to the stance of other stakeholders or to some system of authority. Individual/ personal

decision-making processes may be more coherent, while organizational/ group decision-making processes may be more difficult to generalize along a formal methodology and rather specific to each decision situation. The latter case may indeed hinder the decision makers' motivation and involvement with the decision-making process and ultimately its outcome, if we are to admit that „In order for decisions to actually prompt actions, they must incorporate cognitive, motivational and involvement aspects” [3]. All things considered, the actual decision-process is adapted to the decision situation, including organization regulations and dynamic factors; in all cases one can trace a logic of the decision process and possibly its failures. Therefore, such a process is actually thought of and pursued, and hence worth studying.

Intermediary variations include discontinuous processes and recycling [4], in which decision processes are neither sequential nor chaotic but rather an iterative sequence in which decision-makers react to each “dynamic factor” as it emerges.

If the chaotic paradigm may have overrated the vastness and insufficient regulation of the decision context, disjoint incrementalism risks, on the contrary, to overrate the framing, restrictions and regulations of the decision context. As expected, the stance most often adopted by specialists lays between the two extremes – namely a decision-making model that would capture a wide range of aspects of various natures, and, according to Mintzberg's proposition, to allow for possible shifts in context. Such an approach would combine the control capacity suggested by rationality and sequentialism with the versatility imperative in the face of complex factors such as suggested by the “garbage cans”, and would therefore constitute a sophisticated tool in the decision-making process.

To conclude on the above, just because some decision processes are complex, may not follow the same clear pattern and may ultimately be overturned altogether does not mean that people resign themselves to be placed at hazard's whim and renounce any tentative to influence their state and their environment through self-aware decisions. It is therefore meaningful and useful to study the different ways people come to their

decisions in order not necessarily to establish a best practice, but to gain insight as to what the predominant driving factors are, the point and extent of their influence and the recommendations that could improve people's control over the decision-making process.

3. On the general framework for the decision-making process

This issue addresses a mapping of the process people generally pursue in making decisions. We will only address here individual/ personal decision-making processes, without involving such aspects as organizational regulations, approval systems, negotiations, etc. These form several fields of study altogether, and while such aspects should eventually be integrated in a complex decision framework, we consider this to be a later step in the integration effort. In answering this question we will mention a number of models formulated by different authors in order to finally draw our own conclusions.

In order of complexity, one four-step approach may include: searching for alternatives, estimating consequences, assessing the alternatives and finally making the choice [3]. The same number of four steps can be described in more detail as follows: structuring the decision process, assessing the possible implications of each alternative, determine decision makers' preferences and values, and finally analyzing and comparing alternatives [5]. Another version of decision-making would be segmented into: exploring possibilities, including familiarizing oneself with the decision problem, assessing options and testing premises, and finally learning from the experience [6]. While summarizing in part the analysis in itself, this model also introduced an additional element, namely the dynamic and evolutive nature of the decision-making process. In other words, the decision maker learns from his/ her own mistakes and successes and adapts the process accordingly. Perhaps one of the most detailed general model is described as being composed of: defining objectives, assessing each objective's importance, ordering options, assessing each option's chances of reaching

the objectives, choosing one option to follow through and finally changing the objectives according to the decision outcome [7].

Based on the above we will suggest a description of the decision-making process that combines the details observed separately by the different researchers and thus satisfies their different perspectives (we mention that steps 5 and 6 are carried out after the decision has been implemented and after it has manifested its consequences):

1. Defining the problem, which in its turn consists of:
 - a. Setting objectives
 - b. Establishing criteria for achieving the objectives and the relative importance of each criterion
 - c. Identifying initial position in the achievement of the objectives
2. Establishing possible alternatives/ options
3. Establishing the consequences of each option by means of each established criterion
4. Comparatively assessing alternatives and choosing one
5. Re-assessing objectives set initially and the respective importance of each
6. Analyzing the decision in hindsight and drawing conclusions for similar future situations

These steps seem detailed enough to rigorously describe a process of fundamenting decisions and in the same time generic enough to maintain a character of general applicability. However, a certain number of psychological hypotheses must be met in order to allow for certain decision models, among which those noted above but also expected value theory and expected utility theory [8]. These hypotheses are: independent assessment of alternatives, exhaustive search for information, trade-offs between the characteristics of the same alternative, objective probabilities and objective values. To each of these there is of course an anti-thesis: for instance the one stating that "no theory based on separate assessments of games could possibly work" [9]. Moreover, an extensive search for information could indeed prove unpractical when the information in question is extensive [8]. Across time, numerous researches have been rather inclined to view actual information-seeking as limited [10] [11] [12] [13], yet intended as representative and

meaningful. As information-seeking is an investment in time and intellectual effort, and possible money, this investment may also be sized according to the decision problem structure [14] [15], and most likely the stakes the decision-maker perceives as being involved. The third hypothesis also has its contesters, with non-compensatory heuristics stating that individuals do not in fact make trade-offs between, for instance, the value of an outcome and its probability [8], with empirical studies to support this [16] [17].

Admitting however inherent limitations and imperfections to the structuring of the thought process, establishing a structure is however necessary in ensuring as much as possible a coherent and thorough analysis of the decision issue and therefore maximizing the chances of obtaining desirable results.

4. On the disruptive factors that interfere with the decision-making process

This list would be virtually never-ending, with each field of study involved in the least with human behavior providing constantly new controversies on the subject. I will cite only a few much-debated factors in order to frame the discussion. Factors disruptive to a decision-making process may be structured into factors pertaining to the decision environment, on one side, and factors pertaining to the decision-maker's own person, on the other. The first category involves difficulties that even a perfectly rational decision-maker would encounter in structuring an all-inclusive decision-making model. The second category involves factors of subjectivity and personal characteristics that determine distinct decision-makers to potentially arrive at distinct decisions given the same decision context. There is one particular element in decision-maker that stands at the border of the two categories: the setting of objectives.

Debates regarding the setting of objectives are usually centered around trade-offs between short-term and long-term interests, conflicting interests of various stakeholders, moral concerns, etc. Though general conclusions may be formulated (such as long-term interests ought to be preferred to short-term ones), the issue is too case-

specific to generalize [18].

"Environmental" factors of decision complexity include large time spans, a large number of impacted groups, the interdisciplinary nature of the issue, a multiple number of decision-makers, uncertainty and risk, sequential decisions [5], but also the constant evolution of the decision environment affecting all the previously-stated factors.

Person-specific factors of decision complexity involve the decision maker's past experience, his/ her cognitive style, cognitive biases, motivation, emotional involvement, mood and attitude towards risk. Each of these individual factors has been duly researched. A significant niche for further research rests however with the study of the correlations and interactions between all these factors, and the piece they each play in the intricate puzzle of decision-making. While scholars have already taken steps in this direction (for instance, Nutt took into discussion decision styles, steps in decision-making, and factors that inhibit and mislead decision makers [6]), discussion and integration should be an ongoing academic activity.

In an actual situation of complex decision, any combination of the factors above may come into play: a manager having an innovative problem-solving style [19], with a feeling decision-making type [6], a life experience that would form an entire case study for psychoanalysis, a rather virtues approach to ethics [20], manifesting average risk adversity and being in a relaxed mood [21] may be asked to make a given complex decision in a certain regulatory framework and requiring the approval of two other individuals with a number of different interests and among which certain relations have already been formed.

4. Conclusions

The study of complex decisions is perhaps more complex than its name announces. If thoroughly pursued, however, its results may change the way we perceive our own thoughts, drives and actions. In the vast scientific literature addressing, specifically or in context, a variety of perspectives and details, real-life decision-makers usually faced with great time limitations may not find their way to that one study that could

guide them through the dilemmas they face. It would be therefore useful to put all these perspectives and insights in relation to one another and develop a more comprehensive, more integrated, better structured and more easily-accessible guide through decision-making.

Human Resources Management Using Diversity Managing Tools

Popescu Silvia

"Titu Maiorescu" University of Bucharest

silvipopescu@gmail.com

Abstract

This paper intends to investigate the causal relationships existing between managing diversity and company performance, by analyzing individual diversity at the workplace. Case study was used to indicate possible ways forward in the field of personnel management, and advancement of conceptual thinking in this area. At the individual level questionnaires would be a useful measure, and changes could be visualized by repeated questioning. It tries to demonstrate that a good management of diversity issues in an institution shall exempt the tensions that can arise between different people. The paper explains that a good management of diversity can exempt the tensions that can arise between different people. Productivity will continue to grow due to lack of conflict and motivating employees.

Key words: managing diversity, human resources management, the firm performance
J.E.L. classification: M12.

1. Introduction

The paper addresses not only managers and staff, but all those who experience problems related to (the investigated topic). The nature of the subject is the diversity of staff in an institution and problems that may occur in these conditions. The diversity management literature falls generally into three categories: first are a large number of books, articles, which are focused on both understanding and practice in organizations; second are a number of empirical studies which take a variety of approaches to delineating the effects (ultimately on productivity) of some of the variables related to diversity in the workforce, and; third, is a

much smaller body composed of critical approaches. The main concept used is defined by [3]: "By managing diversity I mean planning and implementing organizational systems and practices to manage people so that the potential advantages of diversity are maximized while the potential disadvantages are minimized". Thus, by eliminating racial prejudice, cultural or institutional, the employer should make efforts to sustain the recruitment of minorities, women, people of color, persons with disabilities and other disadvantaged groups. So we suggest "treat others as they want to be treated", by creating flexible work commitments, accommodation and special training programs. It is proved that such efforts go to a top employer reputation, to flexibility and adaptability for satisfy customer needs and to maximum profit.

2. What is diversity?

Managing diversity is defined as "planning and implementing organizational systems and practices to manage people so that the potential advantages of diversity are maximized while its potential disadvantages are minimized," according to Taylor Cox in "Cultural Diversity in Organizations." Managing diversity well provides a distinct advantage in an era when flexibility and creativity are keys to competitiveness. An organization needs to be flexible and adaptable to meet new customer needs. A simple dictionary definition of diversity is "to make different, to give variety". Applied to organizational life, there are at least three categories of diversity related to performance and strategy. These are structural or functional diversity (differences based on organizational functions and tasks such as administrative vs. operational), business diversity (differences in markets, products and services), and workforce diversity

(different types of employees) .There is not one common usage of the concept of diversity in the organizational literature [19] and [15]. Nevertheless, in the context of employment issues, it is typically discussed in reference to the benefits of variety in work force attributes [8] ; Workforce attributes range from those that are directly related to work or tasks such as differences in skills, to those that are social in nature and –in theory – only indirectly related to work, such as gender. A critical question from a managerial perspective is which attributes become the markers of the dynamics of workplace diversity. Another issue refers to how these attributes affect the experience and opportunities of employees who have them. Professional diversity addresses training and credential requirements to ensure effective performance of diverse tasks. And social diversity refers to variations in the characteristics that identify a person with a social category. Furthermore, there are interdependencies among types of workforce. Any systematic effort to manage diversity in civil service systems must address these differences and the consequences of their interdependencies. The specific configuration of diversity categories to be addressed in an agency, however, is workplace specific. Research suggests that what makes certain attributes salient is constructed in particular social and historical contexts [14] ; [19]. The mix of salient attributes may vary from organization to organization and from society to society. But social categories appear to greatly influence employment contexts in most societies. Social markers include gender, race, ethnicity, religion, sexual orientation, physical ability, age, and family, economic, educational and geographic backgrounds and status. Some scholars distinguish visible from invisible social dimensions and highlight implications for managing diversity [13] . Others also include behavioral attributes such as differences in learning, communication and work styles [12] Primary and secondary social attributes combined produce the “social types” that make up an organization’s workforce[14] , and determine its particular diversity challenges. But the reality of social diversity is even more complicated. Each employee in an organization fits into several potential social categories and, furthermore, many

identities occur simultaneously. In addition, social diversity involves both self-definition and attributes perceived by others; [3] Diversity is generally defined as acknowledging, understanding, accepting, valuing, and celebrating differences among people with respect to age, class, ethnicity, gender, physical and mental ability, race, sexual orientation, spiritual practice, and public assistance status [6] .Managing and valuing diversity is a key component of effective people management, which can improve workplace productivity [1] Dimensions of diversity include, but are not limited to: age, ethnicity, ancestry, gender, physical abilities/qualities, race, sexual orientation, educational background, geographic location, income, marital status, military experience, religious beliefs, parental status, and work experience. It's important to understand how these dimensions affect performance, motivation, success, and interactions with others. Institutional structures and practices that have presented barriers to some dimensions of diversity should be examined, challenged, and removed.

3. What is managing diversity

To address diversity issues, consider these questions: what policies, practices, and ways of thinking and within our organizational culture have differential impact on different groups? What organizational changes should be made to meet the needs of a diverse workforce as well as to maximize the potential of all workers? Most people believe in the golden rule: treat others as you want to be treated. The implicit assumption is that how you want to be treated is how others want to be treated. But when you look at this proverb through a diversity perspective, you begin to ask the question: what does respect look like; does it look the same for everyone? It depends on the individual. We may share similar values, such as respect or need for recognition, but how we show those values through behavior may be different for different cultures. How do we know what different cultures need? Perhaps instead of using the golden rule, we could use the platinum rule which states: "treat others as *they* want to be treated." Moving our frame

of reference from an ethnocentric view ("our way is the best way") to a culturally relative perspective ("let's take the best of a variety of ways") will help us to manage more effectively in a diverse work environment. There are two distinct but connected channels in diversity management, which will lead to superior company performance. The first channel focuses on how to tap into the benefits that flow from effectively managing diversity. The second channel focuses on corrective strategies to address ineffective diversity management, which imposes costs.

4. Benefits of Diversity in the Workplace

Diversity is beneficial to both associates and employers. Although associates are interdependent in the workplace, respecting individual differences can increase productivity. Diversity in the workplace can reduce lawsuits and increase marketing opportunities, recruitment, creativity, and business image [6]. In an era when flexibility and creativity are keys to competitiveness, diversity is critical for an organization's success. Also, the consequences (loss of time and money) should not be overlooked.

There are challenges to managing a diverse work population. Managing diversity is more than simply acknowledging differences in people. It involves recognizing the value of differences, combating discrimination, and promoting inclusiveness. Managers may also be challenged with losses in personnel and work productivity due to prejudice and discrimination and complaints and legal actions against the organization [5]. Negative attitudes and behaviors can be barriers to organizational diversity because they can harm working relationships and damage morale and work productivity [6]. Negative attitudes and behaviors in the workplace include prejudice, stereotyping, and discrimination, which should never be used by management for hiring, retention, and termination practices (could lead to costly litigation)

5. Implications for managing diversity

Increased diversity in the workplace generates interpersonal and organizational challenges that require direct managerial attention. Some employees must learn to interact with members of new groups and managers may have to mediate conflicts. Managers must monitor the extent to which organizational and managerial practices are adapted to address the demographic changes. For example, incorporating more women in the workforce requires wider consideration of family friendly policies and flexible schedules. Having more individuals from a particular ethnic group may require adjusting the dress code and language policies to ensure respect for the life style demands of their religious background or their language traditions. Managing interpersonal dynamics and new policies and practices introduced to adjust the workplace will guarantee that the organization's primary resource – its people – feel welcome as individuals and as organizational citizens.

The interpersonal challenges of diversity

Williams and O'Reilly's review (1998) of research on the effect of diversity on group performance provides compelling arguments for a need to consciously manage the interpersonal dimensions of diversity. Based on empirical evidence from studies in the past 40 years, these authors conclude that variations on group composition can have important effects on group functioning. Williams and O'Reilly argue that "diversity appears to be a double-edge sword" (p. 79). On the one hand, it increases the opportunity for creativity and the quality of the product of group work. On the other hand, it also increases the likelihood of group conflict, member dissatisfaction, turnover and failure in the implementation of ideas. They conclude that "diversity is a mixed blessing and requires careful and sustained attention to be a positive force in enhancing performance" (p. 120). The challenges of managing functional diversity are complicated by the fact that social identities play a critical role in human interaction. Identity theory suggests that managers and their employees tend to experience organizational life and its working dilemmas along identity lines. For example, empirical

studies suggest that employees tend to use both demographic characteristics (such as gender or ethnicity), and functional attributes (such as occupation or organizational position), as salient instruments to categorize themselves and others. Furthermore, employees often use membership in social groups as a proxy of effectiveness in functional performance (e.g. the false claim that women are more effective nurses compared to men). Employees outside a social group also tend to attribute similar values and interests to those inside the group, while they tend to assume easier communication, more trust and higher reciprocity with members of their same identity group. As a result of these and other dynamics, sharing a social identity may highlight perceived differences between social groups. This may lead employees and managers to assume that there are irreconcilable conflict of interests, values and preferences between individuals with different social identities, when in fact this may not be the case [15]. These authors conclude that diversity initiatives in organizations often fail because they do not challenge the generalized assumption that "the needs, desires, values and perspectives of members of different social groups are mutually exclusive". Managers must find ways to show that these can be "congruent or complementary" (p. 1449). They must help diverse individuals find common ground, and this can happen around the goal of organizational effectiveness.

The organizational challenges of diversity

Theories of organizational stratification further shed light on the social psychology dynamics that need to be managed at work. Documentation of patterns of exclusion from society's resources along social identity lines is too large to cite here. Many organizational studies report findings about these patterns for women and minorities in the work place. Examples include the existence in organizations of clusters of jobs occupied by individuals with similar social traits often unrelated to the job, what experts call job segregation, or clusters of persons in occupations and professions who belong to the same identity group, what experts call occupational segregation [18]. These realities produce differential opportunity in processes and outcomes for members of different

identity groups and thus reproduce inequality. For example jobs with large proportions of men tend to have better salaries compared to those with large proportions of women, and so on. Furthermore, studies show that work place inequality has a direct impact on the way employees perceive themselves and others, how they assess the employment relationship and react to their jobs [14]. Hence, attributes associated with social identities cannot be entirely separated from attributes associated with functional requirements for effective performance. The former directly and indirectly affect perceptions and realities about merit and performance in the work place. The challenge of managing diversity in organizations includes the important exercise of addressing issues of social inclusion and exclusion as they affect the experience of work. Organizational and HR mechanisms must be put in place to redress exclusionary practices that may affect the opportunities of diverse individuals. All aspects of the employment relationship, from recruitment and selection to promotion and compensation must be scrutinized carefully [13]; [14]. This must be accompanied by a strong culture that embraces functional and social diversity as organizational values. After all, research shows that if persons believe that their values and norms are not supported and appreciated, their sense of well being, job satisfaction, organizational commitment and task effectiveness will decrease. Indeed, effective management of diversity calls for some degree of reciprocity between organizational and individual cultural systems [13]. Addressing these organizational and interpersonal dilemmas requires managerial will and appropriate organizational mechanisms to translate it into action. The following questions may help managers generate ideas about how to do this systematically:

□ How to minimize the negative effects of diversity on the ability of groups to meet member needs and to function effectively?

□ How to, at the same time, maximize the positive effects of diversity on creativity, organizational justice, better decision-making and increased participation in organizational governance?

□ How to downplay differences across social identity groups interacting in the

workplace and highlight common interests, while valuing and appreciating the contributions that stem from social diversity? and

□ How to ensure sufficient and prompt organizational adaptation of policies and practices, so that the work place becomes a welcoming place to employees who may have been excluded in the past? Answering these questions can help managers develop a diversity management agenda for their organization.

6. Required Tools for Managing Diversity

Effective managers are aware that certain skills are necessary for creating a successful, diverse workforce. First, managers must understand discrimination and its consequences. Second, managers must recognize their own cultural biases and prejudices [11]. Diversity is not about differences among groups, but rather about differences among individuals. Each individual is unique and does not represent or speak for a particular group. Finally, managers must be willing to change the organization if necessary [11]. Organizations need to learn how to manage diversity in the workplace to be successful in the future [7] . Unfortunately, there is no single recipe for success. It mainly depends on the manager's ability to understand what is best for the organization based on teamwork and the dynamics of the workplace. According to [16], managing diversity is a comprehensive process for creating a work environment that includes everyone. When creating a successful diverse workforce, an effective manager should focus on personal awareness. Both managers and associates need to be aware of their personal biases. Therefore, organizations need to develop, implement, and maintain ongoing training because a one-day session of training will not change people's behaviors [11] .Managers must also understand that fairness is not necessarily equality. There are always exceptions to the rule. Managing diversity is about more than equal employment opportunity and affirmative action. Managers should expect change to be slow, while at the same time encouraging change [11].Another vital

requirement when dealing with diversity is promoting a "safe" place for associates to communicate [11] . Social gatherings and business meetings, where every member must listen and have the chance to speak, are good ways to create dialogues. Managers should implement policies such as mentoring programs to provide associates access to information and opportunities. Also, associates should never be denied necessary, constructive, critical feedback for learning about mistakes and successes [7] .A diverse workforce is a reflection of a changing world and marketplace. Diverse work teams bring high value to organizations. Respecting individual differences will benefit the workplace by creating a competitive edge and increasing work productivity. Diversity management benefits associates by creating a fair and safe environment where everyone has access to opportunities and challenges. Management tools in a diverse workforce should be used to educate everyone about diversity and its issues, including laws and regulations. Most workplaces are made up of diverse cultures, so organizations need to learn how to adapt to be successful.

7. Conclusions

Considering, pursuing, managing and maximizing workforce diversity are tasks that will help realize the benefits of this required condition for organizational effectiveness. Yet this cannot happen without organizational leadership, vision and commitment. All members of the organization must choose to meet the challenges and all the managers – senior, departmental, and HR –must assume the responsibility to achieve diversity success by embracing diversity management as the preferred organizational paradigm. A number of organizations across sectors have begun efforts toward managing workforce diversity. In Romania, almost 30 percent of agencies report that they are actively managing diversity. However, very little empirical research has tied diversity management to work group performance or other work-related outcomes. This paper uses a survey of Romania employees to test the relationships between diversity management, job satisfaction, and work group performance.

The overall aims are to help practitioners understand diversity and interaction in organizational change, to encourage the creative use of mixed methods and assist with the application of the approach within a critical framework. Productivity will continue to grow due to lack of conflict and motivating employees. The company will be able to attract and retain talented people, thus saving time, money and efficiency. This paper is another step in social development for the 21st century; she plans on changing mentalities regarding disadvantaged people. I don't think that the efforts discussed here will be needed over several decades. It's just a matter of time until the acceptance and understanding of diversity issues. These results provide a complement to other studies on diversity. Conventional change approaches are seen to be methodologically inadequate to address the diversity and interaction of different types of organizational change faced by today's complex organizations. Critical systems perspectives, while seen to be useful to help address key change issues, are not sufficient alone. By combining critical systems thinking and change management, a systemic framework is seen to be the improved way forward, which emphasizes managing organizational change as a whole, and promoting the use of different change approaches together within a given organizational context. The paper has positive implications for the groups but the statistics still do not look too encouraging. For example, in education the diversity should be supported more intensively. The fact that some people with certain problems may have more developed skills than others should be implemented since early. But many times due to lack of knowledge prevents the deployment. This paper may shed light in supporting various categories of people, for practical and moral reasons. Theoretical implications: As the discussion about diversity management is rather a theoretical and this research stream seems to be underdeveloped with regard to its theoretical foundation, this article represents a first step in strengthening the theoretical foundation. Empirical implications: Data for all three variables (diversity management measures, intercultural competence, and performance dimensions) would be needed for an in depth

examination of the above-mentioned black box. The practical implications: Diversity management matters. At the organizational level, it means that resources should be devoted to diversity management programs and training opportunities. Diversity should be viewed as a core competency for all employees, particularly managers. However, these measures usually focus on relatively small groups inside a company such as executives or young potentials, while diversity management should address all levels of the institute. The literature on diversity management is replete with theoretical assumptions about its relationship with performance. In the sections that follow, I will test some of these assumptions empirically in an attempt to understand whether the data support hypothesized links. I will focus on two of many potentially useful work outcomes: work group performance and job satisfaction. The paper refers to institutional structures and organizations which need creative, flexible and adaptable people to function more effectively and maximize profits. The uniqueness of this paper is precisely this argumentation of the greater efficiency brought by diversity in an institution. In a world where diversity is poorly integrated, where even the polls are reserved, this paper brings the undeniable evidence of the effectiveness of diversity.

Abstract

Human resource management represents all activities of operational and energy order allowing the organization to ensure the necessary human resources and their efficient use. Currently, human problems occupy leading positions in business analysis, although the personnel function has long been almost absent from the economic literature. Quality labor is essential to the success of any organization, in peak areas but also in areas less technologized.

Key words: human resources, management, qualification

J.E.L. classification: J28, M51, M54

1. Introduction

Humans are considered one of the key resources necessary to achieve organizational goals. They are, however, a very special kind of resource. Not only working for the organization - they are the organization. In fact no organization can exist without a human resources component[1].

Good progress of the work of an organization, be it economic or otherwise, is about finding and hiring people to meet job requirements, transposing the the organization's objectives and functions derived therefrom. Managers create a plan to attract and retain people with the skills needed by the organization. Implementing the plan involves the recruitment, selection, integration, training, rewarding, choosing the

most appropriate benefits and continuous assessment of performance to assess whether organizational objectives are achieved. These activities represents components of human resource management[2].

2. A general presentation of "Doina" Hotel

This paper presents the development of human resources within the Hotel "Doina" from Mamaia resort.

"Doina" Hotel is the second in a series of four 10-story hotel. It is directly accessible by car from the main road that runs through the resort of Mamaia.

The resort "Doina" is structured as a limited company and its principal business is in tourism services (accommodation and food) and sale of goods through its own unit. The entire activity is coordinated by the hotel manager, who is also a shareholder and an administrator.

The hotel consists of two buildings: building A - represented by the main building fully dedicated for renting rooms, including the ground floor and building B represented by building where the restaurant works and functions (terrace restaurant and the bar).

3. Analysis of human resources within "Doina" Resort

Resources integrated into the company's activity is presented in a heterogeneous structure, with components having different skills, different hierarchical positions, with different personality features.

Total number of employees of the company is 135, plus two contract employees with temporary benefit: a lawyer and a programmer analyst.

"Doina" resort situated in Mamaia, registered in the period 2007 - 2009, an oscillating trend in the number of employees. Their progress is shown in the chart below.

Graph 1 – The evolution of the employees number

Source: own processing

From the chart shown above, it can be seen that in the period under review, namely the year 2007 - 2009, the total number of employees has decreased, given that 2008 was marked by economic crisis. During this period, hotel management decided to lay off a total of 26 people.

Analyzing staff depending on qualifications, underlines the fact that most employees have secondary education. It appears that the share of employees with higher education is very low (2,22%), while the number of employees with secondary education (10 grades and under 10 grades) is 72%, which practically represents more than half of the total staff.

The chart below is shown the distribution of employees depending on qualifications:

Graph 2 – Distribution of employees depending on qualifications

Source: own processing

Quality of service provided by employees of "Doina" resort depends largely on vocational courses which they have followed. In this case, it can be said that 45% of staff has been improved.

4. Developing human resources plan

"Doina" resort is using a number of **recruitment** methods considered efficiently for this activity. *Internal recruitment method* is used, but a lower percentage. If there is a job release at a higher level, in the hotel, promotion is achieved primarily in the organization, subsequently making calls to external sources. The main recruitment methods used are *external recruitment* methods because of the seasonal pattern activity of hotel. The most common methods are: recruitment through advertisements in the press (the company aims the announcement include the following major parts: conditions of study, training, criminal records, medical records, provided minimum promotion), recruitment based on references from the same branch managers, recruitment in the form of school references (hotel intends to recruit on long and medium term, and has as a target recruiting young and qualified staff and therefore collaborates with colleges such as the Economic High School, School Food Group, Pontica Technical College, School Group Ioan N. Roman).

Selection is the next stage and the first step is the interview. Potential employees are asked questions about enterprise, why are they running for the post, then are presented their responsibilities and duties, working condition (salary, bonuses, travel expenses)[3]. "Doina" Resort is based on two policies that govern the selection of potential employees: policy based on equality (the share of working women is approaching that of men, their responsibilities are distributed depending on the job description) and a policy-oriented young people (young are those who can bring a new spirit in working).

At "Doina" Resort, **professional incorporating** is based on familiarizing the new employee with the new job, the candidate must receive all the information needed, facilitate the accommodation of the working group and, thirdly, there must be a secure atmosphere, confidential. Human

Resources Department has assigned as tasks towards the new employee: explaining the structure of the organization, employee payroll entry, integration planning, assessment of integration activity.

Evaluation processes are closely connected with the promotion of personnel within an organization[4]. General assessment methods apply to any employee of the company, such as major ways: notation, global assessment, functional assessment. Specific evaluation methods are: case, self-tests, self-centers, grading, patterns of comparative personality tests.

Promotion of personnel is a set of processes to assign staff in managerial positions within the company and graduations or larger classes in the same post[5]. Since Doina Resort is a traditional hotel, which operates at a high quality standard, due to employees who successfully complete their tasks, the hotel management was concerned with identifying roots in key elements that motivate them. For this, all 135 employees were interviewed by the board in relation to factors that determine their motivation to work ever more and ever better. In the interview, the board staff presented a number of factors such as salary, working conditions, job content, the team they are part of, opportunities for promotion, financial and economic facilities and organizational culture, and each employee had to elect and justify the factor that motivates them most in their work.

Table 1 – The main motivation factors

Motivation Factors	No. of persons	%
Salary	39	28,88
Workplace safety	28	20,74
Working conditions	19	14,07
Post content	5	3,70
Team they are part of	9	6,66
Opportunities for promotion	24	17,77
Facilities	8	5,92
Organizational culture	3	2,22
TOTAL	135	100

Source: own processing

It can be easily seen , that for most employees **salary** represents the main motivating factor. The importance of salary as a motivational factor emerges from the fact that some people judge their success or failure depending on the money with which they are rewarded for their work. Of those employed, 29 responded that this criterion has the most important part in motivation, its share being 29%.

The economic recession has changed the priorities of employees. If a few years ago economic-financial benefits were most important to employees, now they say that **job security** is essential, therefore it ranks on 2. A percentage of 21% and 28 people, believes that keeping a job is the problem faced by most employees and is also an important motivating factor.

Of the eight motivating factors presented, organizational culture has the least interest to employees, although in the sphere of culture tare are symbols, norms, laws, values, rituals, all forming a style that defines in a special manner every organization. For this criterion have chosen only three of the 135 people employed in "Doina" Resort, weight of this factor being the lowest, respectively 2,22%.

4. Conclusions

Coordinating "Doina" Hotel requires training to achieve good management staff, given the large number of employees exceeding in the peak season also 130 people.

The main problem is lack of trained labor. "Doina" Hotel is also facing this problem. Despite increased efforts by management to keep employees and to create a strong organizational culture reflected on the quality and efficient results, seasonality is a negative factor which is difficult to master. Although, the hotel has built a strong team of 30 permanent employees during several years, that determines the return of tourists every year, is hard, problems arise in recruitment of seasonal staff.

Regarding selection the classical steps taken into account are interviews and various tests, the essential is to compliance with policies governing the selection of prospective employees: policy based on equality and youth orientation.

Another direction set by the hotel unit in 2011 is to implement quality system for objective evaluation of employees regarding pay-performance ratio.

After analysis motivational factors it was found that the main criteria that determine hotel employees are: salary, working conditions and job security. In this context it is quite challenging for the hotel to create a culture where employees put quality consumer services on the first place.

Abstract

What this paper suggests is taking a quick look on the everyday managerial reality through a rather original lens. This way, the economic ciclicity begins to be comprehended for what it really is: a key ingredient in any business activity; but, and unfortunately so, an often times ignored one, especially when it comes to making important strategic decisions. For the most part, counter-intuitive measures applied with a perfect sense of timing in the uncertain global business world seem to add up to that sixth sense only a few lucky players appear to be equipped with. But of course, it all goes beyond that, pointing towards an intimate understanding of the economy cycles and the signs/tools helping to predict their unfolding. Hence, intrigued by this realization, our aim would be to emphasize the importance of mastering the different stages of the business cycle, as well as the set of skills and information much needed in order to successfully navigate through this ceaseless economic roller-coaster.

Key words: economy cycles, management strategies and tactics, competitive advantage

J.E.L. classification: D20, L20

1. Introduction

We live in a complex world, acutely defined by uncertainty more often than we think about it and certainly more dramatically than we would like to feel on our own skin. What everyone calls the “financial crisis” started in 2008 - the economic disaster we are so much struggling to leave behind us – stands as the most vivid proof of this fact. If we look back only along the past century so do, among others, the great depression burst

in 1929 (a recurrent point of comparison for what we experienced lately), the oil crisis of 1973 and even the burst of the dot-com bubble in 2001.

These troubling phenomena are nevertheless effortlessly explained by what illustrious minds introduced in the economic theory as economy cycles. According to their legacy, such difficult periods are nothing more than natural contractions of the business cycle called recessions and implicitly following every blossoming stage from an economic point of view. In other words, if we may put it very bluntly, mankind seems to be doomed to ever-riding an authentic economic roller-coaster, with nothing but mere fatality to offer us some peace of mind. The cycle always dictates its well pre-known history: when economy is good - companies thrive, when it goes down the descending slope again – things can go from bad to very bad to bankruptcy. Moreover, everybody wins and loses according to this scenario. Jobs are created in flourishing times only to be lost again when crisis strikes, affecting the livelihood of the individuals depending on those incomes. Also, investors of all kinds play the same risky game, only hoping to be smarter this time around.

But then again, if it’s all so natural and especially if we should have already gotten used to this reality, why do we keep falling in the same trap? More precisely – why haven’t we adapted? Why haven’t we already learned to manage the business cycle, to prevent what can be prevented and essentially prepare for the bad days while still enjoying the good ones, as trivial as this may sound?

Well, maybe it’s not that simple. As we commenced, it is indeed a complex world we live in and things are not always what they seem to be at a first glance. Nevertheless,

there are cases in which a broader perspective and a deeper insight have brought amazing results. There are cases in which bright managers have not only learned to strategically face up to the inherent challenge of economy cycles, but they have also learned to exploit the opportunities presented in their expansionary and recessionary points. How is this possible? This is the question!

Our journey departs from this ambitious prospect of regaining faith into the very nature of economic reality and grasping the enormous potential that lays within. This being said, we believe that the secret in doing that resides in the complete understanding of this particular economic process and of the exact ways in which strategic thinking plays a role within it. After thoroughly completing these two lags, we shall expose our conclusions and recommendations for future research deduced from them.

2. Economic cyclicality: an overview

The term economic cycle (or business cycle) refers to economy-wide fluctuations over several months or years, usually measured through the growth rate of real GDP. As it can be observed in the graphical representation below, these fluctuations occur according to a long-term growth trend involving recurrent shifts in time between periods of relatively rapid economic growth - expansion or boom periods - and periods of relative stagnation and decline - contraction or recession (O'Sullivan & Sheffrin, 2003).

Figure 1: Graphical representation of economic cycles

Source: <http://www.wikinvest.com>

It was the French economist Clement Juglar who, in 1860, identified economic cycles of 8 to 11 years, being cautious enough not to claim any rigid regularity in their occurrence.

Later on, Schumpeter argued that a Jugular cycle has 4 stages:

- Expansion (increase in production and prices, low interest rate)
- Crisis (stock exchange crash and multiple bankruptcies)
- Recession (prices and output drop, high interest rate)
- Recovery (stocks recover because of the fall in prices and incomes)

Following these reflections, he proposed in the *History of Economic Analysis (1954)* a typology of business cycles according to their periodicity and named after their discoverers / proposers:

Table 1: Business Cycles classification

Cycle / Wave Name	Years
Kitchin inventory	3-5
Juglar fixed investment	7-11
Kuznets infrastructural investment	15-25
Kondratiev wave	45-60

It is fair to say that the development of modern macroeconomics has left these typologies of cycles in a shadow. There is little support for the idea of regular, periodic cycles, especially due to the multitude and complexity of endogenous and exogenous factors that could be charged with their occurrence. Despite the remarkable efforts of great economic thinkers such as Schumpeter and others following in his steps, one cannot convincingly argue nowadays that economic cycles, even named as such, do follow a predictable periodic pattern.

And still, they do occur. History offers a myriad of evidence for frequent crisis in Europe and America ever since the beginning of the 19th century. Other similar events are recognizable before this period as well, going back in time up to debasements of currency and sovereign defaults, which were forms of crisis prior to the 18th century (Reinhart & Rogoff, 2009).

Under the irrefutable proof of centuries and centuries shaped by economic ups and downs of all sorts of causes and influences, we find ourselves even as we speak traversing one more of these phases. The

crisis effects are visible in every aspect of human life. But, as it attacks the deep levels of our economic fabric, this is the where we track it and try to nail it down. Usually recognizing the danger too late, ill-equipped decision makers do their best in sailing big or small company-ships in the descending waters of the business cycle. Escaping or not the cruel bottom of the ocean, their sometimes remarkable efforts can not compensate for haemorrhaging cash and people during recession.

Consequently, it seems as if a central puzzle piece is missing from this rather sombre landscape, one that might just turn it into a hopeful scenario. One that can pinpoint exactly how there is no danger in economic cycles, but rather different opportunities in its expansionary and recessionary points and always the possibility to hedge business cycle risk. As startling as it might sound, the missing element we are talking about is nothing more than pure strategic thinking, with all its intriguing facets.

3. A strategic approach to economic cyclicality

Despite the great and intricate impact of economic cyclicality upon our fates, up to a few years ago there was a monumental gap in the management literature, where in fact should have stand a comprehensive explanation about how to strategically and tactically manage the business cycle. Peter Navarro, the one who first saw the need for a connection between economy cycles and business strategy, even dares to call it the "black hole" of corporate strategy, since business cycles represent one of the most important determinants of corporate profitability and stock price performance.

Through the Master Cyclist Project, an extensive research conducted over 5 years at the Paul Merge School of Business at the University of California-Irvine, Navarro and his colleagues tried to answer the following question:

"How can the modern executive team strategically and tactically manage through the various recessionary and expansionary phases of the business cycle to gain competitive advantage over rivals?"

Drawing on hundreds of examples from around the world, from the economy giants to the very small companies, the results of this study (Navarro, 2006) bring to life simple principles for managing economic upswings and downswings, that make appeal to strong analytical thinking as a basis for a sharp sense of timing and anticipation. Consequently, these principles defining every "Master Cyclist Manager" target every compartment of business life, from the generic units such as Production and Inventory Control, Marketing and Pricing and Human Resource Management up to Risk Management, Capital Expenditures, Acquisitions and Divestitures.

Building upon Navarro's fascinating findings, we would like to further on underline concrete measures that can be implemented at different business levels in order to smoothly navigate through the economic cycle. Some of them might seem bluntly counter-intuitive, which is exactly why most managers do not apply them and instead end up being "fooled" by the natural unfolding of the business cycle, luring them into ill-timed and ill-considered reactions to the external conditions.

Adopting the already famous common belief that the people are a company's principal and most valuable resource, we would add that this fact becomes even more so applicable during a recession. Why? Because, as odd as it might sound, this is the best time to hire more people. During the recession, the labour pool is at its deepest and highest quality. Add this to the fact that labour contracts are much easier to negotiate in a bad economy and you come up with the best time to "cherry-pick" talents, who will most probably further on help you overcome the challenging financial situation.

In a similar manner, marketing and brand management experts should build the brand and market share through countercyclical advertising. Given the fact that during a crisis period consumers respond better to advertising messages relying the value of the product and not its style, the product mix and advertising message should be alternated in order to fit the stage of the business cycle. Such measures, coupled with adapted price tactics and targeting techniques can really make a big difference.

Another very important aspect is represented by the capital expenditure segment. A good manager senses when the level of capital expenditure reaches a certain peak and will choose to counter-cyclically cut its volume in anticipation of recession. This simple tactic has the power to save many companies from bankruptcies by assuring a comfortably large cash reserve for darker days. Just as unexpectedly, capital expenditure is encouraged during recession (with the condition to have endured enough funds beforehand) in order to develop innovative products and new capacities in time for recovery.

But, just as Navarro puts it, when you can't beat the business cycle what else is left to do than to hedge its risks? Managing business cycle risk can be done through a series of well-timed strategies and tactics, out of which the most played with are hedging instruments such as options, futures and swaps. Other risk management tools would be business unit diversification and geographical diversification. While these can be employed also in order to achieve economies of scale and scope, fine-tuning them with business cycle can bring enormous advantages. Since business cycles and political conditions of various countries are not perfectly correlated, it's not hard to learn in which directions to take the winning moves, especially in our increasingly global economy. Last but not least, true riders of the business cycle learn how to speculate the underlying conditions of a crisis and adapt by developing new products and markets in response to macroeconomic shocks that might have marked the beginning of a recession period (war, terrorism etc.)

Understanding the fine logic behind these custom strategies makes the difference between success and failure more and more often nowadays, thus the line is drawn between business cycle-savvy managers and those who either don't see the big picture or don't have the courage to act upon such counter-intuitive measures.

4. Concluding remarks and suggestion for future research

Arnoldo Hax, professor at the Sloan School of Management, thinks that "the essence of strategy is to achieve a long-term advance over the firm's competitors". If we take into consideration that external business factors for competing companies in any given field are more or less the same, then their success depends largely upon their internal strengths and the capacities to deploy these strengths when and where they are needed. Among these, a well thought-through and carefully implemented strategic plan is maybe the most important one of all, as being granted to practically sustain a leader's vision and make the company stand out from the crowd in every way.

With economic cyclicality interfering into the regular business development path, such ambitions become much more than just salutary – they become the only sure and sought-through way to success. As random macroeconomic shocks provoked by either mankind or mother nature madness throw companies into the tumult of recession, economics has gained a bad reputation as the "dismal science". In fact, we believe this is only pessimistic in-take on such events. Chaos in general presents both danger and opportunities and so do economically chaotic time frames. The only difference lays as usually in our attitudes – this is why this articles purpose was first and foremost that of a paradigm shift towards a positive and opportunistic attitude. And if some of the proposed strategies and tactics may seem somewhat Machiavellian or resting too much on a fine sense of timing with the different stages of the business cycle, then so be it. If it won't be the manager of one company thinking or reading about them, there will most probably be the manager of a competitor who will.

Concluding, since we find ourselves exactly in the VUCA¹ world, maybe we should try to deepen the principles of this acronym and, why not, even see how they fit with the strategic approach for economy cycles. Volatility, uncertainty, complexity

¹http://en.wikipedia.org/wiki/Volatility,_uncertainty,_complexity_and_ambiguity

and ambiguity - all these elements present the context in which organisations view their current and future state. Maybe a similar framework should be built for the case we tried to make with the present paper, in which similar premises as those of VUCA will enhance an organization's capacity to:

- Anticipate possible issues related to business cycles
- Fully understand the consequences of their actions under changed business cycle conditions
- Appreciate the interdependence of variable within the business cycle stage context
- Prepare for alternative realities and challenges brought by shifts in the business cycle
- Interpret and address relevant opportunities brought by the business cycle stage

We believe the importance of such a conceptualization is crucial, especially in our complex socio-economic and political world arena. But maybe once again Peter Navarro puts it best:

"In an increasingly global and fiercely competitive economy, the line between corporate success and failure is now being drawn by the ability – or lack thereof – of the modern executive team to first understand the business cycle in all of its strategic and tactical richness and then proactively manage that cycle for competitive advantage."

Last but not least, let's not forget that all of this is in the end for a higher purpose, for building a better world for our children to grow up in, full of love, opportunities and abundance. Isn't this what it's ultimately worth fighting for? We strongly believe in a positive answer.

Abstract

This paper aims at defining, measuring and determining the effects of the underground economy. Consequently, it focuses on the specific aspects of every type of assessment method used in the specialty literature of this phenomenon and the possibility to apply them to the realities of the Romanian economy. Underground economy is a fact of life in the entire world, with clear signals of becoming more and more extensive, reaching remarkable dimensions and offering serious grounds for concern over the past few decades.

Key words: underground economy, assessment methods, DYMIMIC method

J.E.L. classification: E26

1. Introduction

The economic realities of the past few decades, with a globally extensive underground economy, more or less present in every country of the world, have shown that the efficient strategies against this phenomenon are not those targeting to eradicate it, but those who control it. Under these circumstances, the globally wide-spread activities of the underground economy have become an even more recurrent preoccupation, both at the international organizations level, as well as the country level and that of leading political groups active in every state. As a consequence of this situation, more and more economists have tried to define, measure and determine the effects of the underground economy.

The dimension of the underground economy in Romania is a very important indicator, just as in all the ex-communist

European countries. Being easily observable even in the statist period, this phenomenon continues (and with too much success even!) its perennial existence even in the new market economy. Tax evasion, which can not be tied only to the democratic period of the '90s, is being observed and discussed ever since the beginning of the 20th century.

The underground economy is defined as the sum of organized economy activities which break the social and economic legislation norms, with the purpose of gaining revenues that can not be controlled by the state.

Globalization and regionalization also facilitate the worldwide underground economy. New communication systems and advanced technology have shortened the distance between states, have opened the borders and created unimaginable opportunities for political or social interactions, but also extension. Assessing the underground economy is an important stage, essential for knowing the status-quo and the long-term consequences of economic and - most importantly - fiscal policy decisions, both the direct but especially the indirect ones.

2. Conceptual delimitations and assessment methods

The underground economy has entered the specialists' spot-light ever since the '60s, when the phenomenon has taken a great extent. The first academic paper in which the problem of underground economy is noticed and made public belongs to the American P. Gutmann, who, in 1977, estimated that the statistically unregistered economic activity can no longer be considered a negligible entity. Regarding its motivation, V. Tanzi sees the development of underground

economy as a product of two large categories of factors: those tied to the desire of escaping taxes and those tied to the desire of avoiding governmental rules and restrictions.

The object of our paper appears in the academic literature under various names (more than 20): „occult economy”, „hidden”, „dissimulated”, „parallel”, „annex”, „dangerous”, „ghost”, „invisible”, „unofficial”, „dual”, „cash”, „informal”, „secondary”, „illegal”, „grey”, „shadow”, „unmeasured”, „counter-economy”, etc.

The difficulty in defining the underground economy, generated by the diverse activities it reunites and by the fact that these activities vary according to space and time particularities specific to this type of economy, determined the birth of a multitude of longer or more restrained definitions in the academic literature. These numerous definitions mainly express the opposition of underground economy in relation to the official economy, the legislation and respect for ongoing rules. This way, the concept of underground economy largely reunites those activities whose existence is not officially known (accounted for) and whose associated incomes do not make the object of fiscal declarations.

If on a national basis one can find a variety of definitions for the underground economy, at an international scale a universally accepted definition is still looked after. Therefore, it has been convened that the underground economy definition should include two aspects:

✓ The underground economy is the one “escaping” statistical records and precise quantification;

✓ Activities of the underground economy must be expressed in G.D.P. terms, so that a comparison between the size of the underground economy and the officially measured G.D.P. is possible.

Generally, it is thought that, in economically developed countries, legal undeclared activities with the purpose of evading the payment of fiscal obligations account for the most important part of underground economy, while in developing countries, because of a very strong auto-consumption and the limited possibilities for statistical recording, the conventionally unaccounted for production is very high, surpassing often the official economy.

Fraudulent tax evasion represents an important part of the Romanian tax evasion. In comparison to other countries, where the percentage of underground economy components is about 50%, in our country it is very likely that this percentage is higher because of at least two reasons: crime, prostitution, drugs, money laundering are still at unreasonably high levels, while there exist extremely favourable conditions to fraud the fiscal system so that this phenomenon becomes even larger and eventually surpasses the growth rhythm of the official economy.

Analysing the studies and references of underground economy leads us to the conclusion that three main approaches can be identified in order to determine its size:

➤ Launching some speculative numbers, according to certain situational interests. The role of such “estimations” is that of convincing the public and the media that the entitled entities will adopt the right measures when noticing the dimensions of activities escaping legal

➤ Releasing some numbers according to a purely logical reasoning and a good knowledge of economic activity (both formal and informal), this type on analysis offering many times some pertinent figures, at least when the author is a very well assessor of the reality in its own country, has the specialty training and the intuition for such an attempt. An important role when taking this approach is played also by performing international comparisons with countries having a similar economic structure and educational and behavioural characteristics of the population.

➤ Estimations based on well-defined assessment methods, for which certain calculus methodologies are elaborated and built upon the idea that underground economy leaves certain marks easily traceable on the labour market, in monetary aggregates or under the form of incongruence incomes and expenditures.

According to this last path for determining the size of underground economy, the following general approaches are known, each of them offering the possibility of different practical assessment methods:

- Methods based on data from the national account system;
- Assessment based on data obtained from fiscal verification and control methods;

- The method of labour market parameters;
- Monetary methods;
- Methods based on the electricity consumption;

A few other methods have been perfected at an international level, having to mention though that their results are rarely concordant when applied to the same country and time frame.

- The most obvious one is *the direct surveillance through data offered by companies whose activity is performed fully or partly within the frameworks of underground economy*. This method offers an insight of the underground economy structure, but is based on the accuracy of the data, which is usually untrustworthy, especially since some of the activities are illegal and those companies are not ready to admit their implication, even under the protection of anonymity.

- A similar method is based on *the detailed analysis of a sample of tax payers under the threat of being sanctioned, should they refuse to collaborate*. Without covering an important part of the underground economy, this method achieves obtaining data about the tax evasions of little dimensions, performed by those who work independently and usually avoid paying the taxes owed to the state.

Despite the advantage of detailed information, because of the evident disadvantages (data subjectivity and the impossibility to perform evolutionary projections of the underground economy) these methods are not very used in practice.

More objective and precise are the indirect assessment methods of the underground economy, based on discrepancies in the evolution of different markets.

- *The method of expenditures discrepancies* – people who work in the underground sector spend more than their declared income. This discrepancy, reflecting the quantum of the underground economy, can be emphasize both at the individual level as well as the national financial system level.

A way of measuring the underground economy pertaining to this method is by comparing the results registered in the national account system, during the process of determining the G.D.P. through the

incomes method and through the expenditures method. Usually, the first method offers lower numbers than the second one. The “unexplained residue” from this difference can serve as a basis for estimating the size of the parallel economy.

This method has the advantage of a simple and easily applicable calculus and the possibility to explain the general evolution of the occult economy by following the relative measure of these differences each year.

At the same time, there seem to be a series of disadvantages as well, among which :

- ✓ Errors in estimating both aggregates;
- ✓ Errors caused by differences in statistical coverage;
- ✓ G.D.P. estimations are not always independent of estimating the income on the basis of fiscal data (un noticed income by the fiscal authorities can be absent in the national accounts as well).

Financial audit programs are especially used for estimations. The problem with this method resides in the embedded errors, both measurement and substance errors - for example, by not taking into consideration the possibility of higher expenditures through contracting a bank credit. Moreover, samples used for financial audit programs are not representative for the entire population of a country.

- *The method of discrepancies on the labour market* – an unjustified decrease in the labour offer can be simultaneously considered an increase in underground economy, while also this estimation is affected by interpretable elements. In most of the cases, people work both in the underground economy, as well as in the official one, therefore this estimation method is less used. Nevertheless, its main advantage is that it permits taking into consideration not only those activities paid for in cash, but also those paid for in nature, this modality of payment being far from negligible.

- *The method of transactions discrepancies* – an estimation method perfected by Edgar Feige and departing from the premise of a constant relation in time between the volume of transactions in a given country and the official G.D.P. In order to estimate the level of underground economy, Feige started from a basis year when there was no underground economy and further on took into consideration a “normal” volume of

transactions that would remain the same over the period of several years. Naturally, all these assumptions make the accuracy of the obtained data highly questionable. Moreover, it is difficult to estimate the volume of transactions, especially those undergone in cash.

- *The method of discrepancies on the monetary market* – the discrepancy visible on the monetary market lays at the base the most used assessment method of the underground economy. This one starts from the premise that unofficial transactions are accomplished in cash in order to make their discovery by the authorities more difficult. The level of underground economy is thus brought forward by the extra cash quantity used at the national level in comparison to cash quantity associated with official transactions. This method is considered to be more exact, as the structure and quantity of the money supply are generally known in detail. Nevertheless, it should be pointed out that even unofficial payments are sometimes performed via bank or electronic means.

Three methods implying the monetary approach of the underground economy are practically known:

- Considering the fact that releasing a growing quantity of high value denomination in order to facilitate payments would prove the existence of underground activities, some try to validate the idea that the size of informal activities could be determined this way. By simplifying a very complex reality, this method rather gives clues of the trends manifested in this field, than a fairly pertinent idea of its size.

- The transactions method starts from the hypothesis that there is a constant relation in time between the cash transactions volume and total G.D.P., official and clandestine. This method is based on Fisher's well-known quantitative relation: $M * V = p * T$, where:

M- money supply

V- velocity of money

p - price level

T- volume of transactions

By observing the total money supply M, which contains both the actual quantity of money and the demand deposits, the size of total G.D.P. can be deduced. From this value, the official G.D.P. is further on deduced in order to obtain the clandestine G.D.P. as a residue in G.D.P. terms. The underlying

supposition is that the velocity of money is equal in the two sectors (legal and illegal).

- The most frequently used method from this category is the one founded on the ratio between the circulated money and the demand deposits, owned by the banks. It states that clandestine economy transactions are reflected in the modifications of this ratio. This way, supposing the velocity of money is the same in the occult economy and in the official economy, any significant increase in liquidity demand in comparison to the demand deposits can indicate an expansion of unofficial activities.

The criticism brought to these monetary methods refer to their underlying hypothesis:

- implying the choice of a base year with a supposed level of clandestine economy, usually considered zero;

- cash transactions, even in this sector, are more and more frequently performed by checks and other modern payment methods;

- the velocity of money considered equal in the two sectors is very hard to determine even for the official economy, let alone for the informal one.

- Modelling the underground economy and defining it as a system is a practice employed by modern assessment method of the underground economy – the method of electricity consumption – introduced by Maria Lacko proposing the determination of the underground economy level in several European countries with the help of one model. The premise for this model is that a part of family consumption of electricity in every country is used in the underground economy. Thus, households' consumption of electricity in a given country is not determined only by evident factors such as population size, standard of living, geographical position (for climate implications), the relative price of electricity or the access to alternative sources of energy. On the other hand, a significant percentage of the unregistered companies perform their activities within individual households, obtaining income.

- Assessment based on data obtained as a result of fiscal verifications and other control methods. Starting from the data obtained by fiscal authorities during control operations, this method ignores voluntary questionnaire-based responses. It permits a thorough understanding of the situation,

underlining those profession declaring lower incomes than the real ones or not declaring any income at all.

One of the problems with this method, suggesting that the obtained results are much more diminished than the real ones, is the high number of people who don't fill out any fiscal declaration and are only discovered by total accident from time to time.

- A distinct method from those exposed above is the DYMIMIC method (dynamic multiple-indicators multiple-causes). It takes into consideration multiple causes that determine the appearance and extension of underground economy, as well as its multiple effects in time. Based on the statistic theory of unobservable variables, the method consists in two parts which tie the unobserved variables to the observed indicators. In this case there is only one unobserved variable – the size of underground economy. The hypothesis bring a set of causes and a set of indicators influenced by the size of underground economy, this way the structural dependence of underground economy from these variables is emphasized, the dependence being used for foreseeing the future modifications in size of the underground economy.

3. The dimensions, causes and consequences of the underground economy

A high underground economy has as main negative effects a lowering growth ratio of the official economy. In Romania, statistical data regarding this phenomenon are concerning, as the negative effects of the high underground economy are strongly felt both in terms of G.D.P., as well as of tax receipts. In 2010, our country had an underground economy of 30.2 % of G.D.P din, being surpassed only by Bulgaria from this point of view. The average for the UE-27 countries is of 20% of G.D.P., which gives our country 10 percentage points above this average, an interval with potentially considerable amounts for the public national budget, if fiscal discipline would accentuate.

Figure 1 shows us a percentage of underground economy of 15% in the Nordic countries, Austria, Germany, France, Ireland, the UK, Luxembourg and Holland. Even for these states with lower values, the percentage of underground economy must be controlled, since even the lowest value is still considerable - 8,67% in Austria.

Figure 1. Underground economy in UE countries in 2010

Source: Prof. Friedrich Schneider's estimations

Analyzing the evolution of underground economy between 2003 and 2010 and comparing Romania with the average of UE-27, a slight decrease in the size of this phenomenon is notices, with around 2 percentage points, both for our country and for the UE-27 average. The difference between Romania and UE-27 is relatively

constant though, of about 10 percentage points, which evidently reflects a systemic problem of our economy. In 2009 Romania was the second last EU country in terms of G.D.P. per capita, with 45% of the UE average, followed only by Bulgaria.

In May 2010, underground economy was estimated at 35%-40% of G.D.P. Tax evasion

in the food industry reaches 7-8 billion euro annually, while other 2 billion euro are lost

through tax evasion with tobacco, alcohol and petroleum products.

3.1. Identified tax evasion

a. identified tax evasion in Romania - % of G.D.P.

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of identified tax evasion in G.D.P.	1,80	1,71	1,76	1,77	2,80	2,75	2,87	2,34

b. identified tax evasion in Romania - % in fiscal revenues of consolidated national budget (C.D.P.)

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of identified tax evasion in fiscal revenues of C.D.P.	6,51	6,26	6,33	6,19	9,66	9,82	10,07	8,36

3.2. The evolution of underground economy in Romania

a. NIS methodology

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of underground economy in the official G.D.P.	14,3	14,5	16,6	19,2	20,0	19,6	21,3	23,5

b. DYMIMIC methodology (professor Friedrich Schneider)

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of underground economy in the official G.D.P.	33,6	32,5	32,2	31,4	30,2	29,4	29,4	30,2

This is how the percentage of underground economy in the G.D.P. is expressed for the UE-27 countries and for

other 4 European states, according to the DYMIMIC methodology:

Year	2003	2004	2005	2006	2007	2008	2009	2010
Romania	33,6	32,5	32,2	31,4	30,2	29,4	29,4	30,2
Austria	10,8	11	10,3	9,7	9,4	8,1	8,47	8,67
Belgium	21,4	20,7	20,1	19,2	18,3	17,5	17,8	17,9
Bulgaria	35,9	35,3	34,4	34	32,7	32,1	32,5	32,9
Cyprus	28,7	28,3	28,1	27,9	26,5	26	26,5	26,8
Czech Republic	19,5	19,1	18,5	18,1	17	16,6	16,9	17,2
Denmark	17,4	17,1	16,5	15,4	14,8	13,9	14,3	14,4
Estonia	30,7	30,8	30,2	29,6	29,5	29	29,6	29,9
Finland	17,6	17,2	16,6	15,3	14,5	13,8	14,2	14,3
France	14,7	14,3	13,8	12,4	11,8	11,1	11,6	11,7
Germany	17,1	16,1	15,4	15	14,7	14,2	14,6	14,7
Greece	28,2	28,1	27,6	26,2	25,1	24,3	25	25,2
Ireland	15,4	15,2	14,8	13,4	12,7	12,2	13,1	13,2
Italy	26,1	25,2	24,4	23,2	22,3	21,4	22	22,2
Latvia	30,4	30	29,5	29	27,5	26,5	27,1	27,3
Lithuania	32	31,7	31,1	30,6	29,7	29,1	29,6	30
Luxemburg	9,8	9,8	9,9	10	9,4	8,5	8,8	8,8
Malta	26,7	26,7	26,9	27,2	26,4	25,8	25,9	26
Holland	12,7	12,5	10	10,9	10,1	9,6	10,2	10,3
Poland	27,7	27,4	27,1	26,8	26	25,3	25,9	26,1
Portugal	22,2	21,7	21,2	20,1	19,2	18,7	19,5	19,7
UK	12,2	12,3	12	11,1	10,6	10,1	10,9	11,1
Slovenia	26,7	26,5	26	25,8	24,7	24	24,6	25
Spain	22,2	21,9	21,3	20,2	19,3	18,7	19,5	19,8

Slovakia	18,4	18,2	17,6	17,3	16,8	16	16,8	17,3
Sweden	18,6	18,1	17,5	16,2	15,6	14,9	15,4	15,6
Hungary	25	24,7	24,5	24,4	23,7	23	23,5	23,8
Average EU – 27	22,3	21,9	21,5	20,8	19,9	19,3	19,8	20,0
Croatia	32,3	32,3	31,5	31,2	30,4	29,6	30,1	30,3
Switzerland	9,5	9,4	9	8,5	8,2	7,9	8,3	8,34
Norway	18,6	18,2	17,6	16,1	15,4	14,7	15,3	15,4
Turkey	32,2	31,5	30,7	30,4	29,1	28,4	28,9	29,2
Average Europe – 31	22,4	22,1	21,6	20,9	20,1	19,4	19,9	20,1

3.3. Assessing unidentified tax evasion based on underground economy

a. NIS methodology (according to NIS estimation, unidentified tax evasion is on average 2/3 of the entire underground economy)

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of unidentified tax evasion in official G.D.P.	9,53	9,67	11,07	12,80	13,33	13,07	14,20	15,67

b. DYMIMIC methodology

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of unidentified tax evasion in official G.D.P.	16,8	16,25	16,1	15,7	15,1	14,7	14,7	15,1

3.4. Total tax evasion

Total tax evasion = identified tax evasion + unidentified tax evasion

a. NIS methodology

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of TOTAL tax evasion in official G.D.P.	11,33	11,38	12,83	14,57	16,13	15,82	17,07	18,01

b. DYMIMIC methodology

Year	2003	2004	2005	2006	2007	2008	2009	2010
Percentage of TOTAL tax evasion in official G.D.P.	18,60	17,96	17,86	17,47	17,90	17,45	17,57	17,44

These values determined through the DYMIMIC methodology are much more credible (both as values per-se, as well in

terms of the trend they show) than those determined through the simplifies methodology of the NIS.

3.5. The perception index of tax evasion in Romania according to WORLD COMPETITIVENESS

Year	2003	2004	2005	2006	2007	2008	2009	2010
Perception Index of tax evasion	3,85	1,36	2,27	2,04	3,13	3,21	1,68	2,09

Specification: this index is established on a scale from 0 to 10, where 10 is the country with a practically inexistent perceived tax

evasion and 0 defines the perception of a state with the highest tax evasion.

4. Conclusions

The underground economy has become an omnipresent phenomenon of the social and economic sphere. Its amplitude is concerning because, with lacking control methods, it can violate the future stability of the national economy.

From an economic point of view, a balanced situation of the state budget would lead to a macroeconomic equilibration and the assurance of conditions for economic development.

In order to fight tax evasion it is not necessary to impose drastic sanctions – an efficient fiscal control should be achieved, a viable legislative system and, maybe first and foremost, a fiscal education of the citizens.

Fiscal laws must be simple, clear, precise and relatively stable, in order to facilitate the distinction between cases when laws are broken with a fraudulent intention and those when they are violated by negligence or for reasons independent of the taxpayer's will.

Our country had one of the best fiscal procedure codes, which was unfortunately abrogated by the dictatorial regime installed after the 2nd World War. Therefore, it is necessary to reorganize the fiscal control and verifications and for the Romanian National Bank to establish clear norms regarding the conditions to be fulfilled and the documents to be presented by physical persons.

Using Ontologies in the Design of Forest Accounting Information Systems. Literature Review.

Postolache (Males) I. Daniela
"Alexandru Ioan Cuza" University of Iasi
males_daniela@yahoo.com

Abstract

In our paper, we conducted a literature review, in the field of accounting information systems ontologies. Our results are useful to researchers and developers of decision support intelligent solutions, to forestry accounting researchers and forestry managers, to be aware of new discoveries in the field, to managerial accounting researchers interested in using economic models for decision support tools development.

According to various studies, the use of ontologies in business information systems design can bring solutions to optimize the integration, the implementation of extensible interfaces, the availability of a common vocabulary, objectively specifying of information, to facilitate the sharing and reuse of information. For forestry information systems, using ontologies has proven to be beneficial in solving a thorny problem: the incompatibility of data. The requirements for ontologies in this area are: robustness, flexibility in communication and interconnection, extensibility.

The conclusion drawn from the study is that the use of ontologies is needed in designing accounting information systems.

Key words: ontology, accounting information systems, forestry decision support systems.

J.E.L. classification: D83, M15, Q55, Q56

1. Introduction

Development, diversification and widespread use of modern information technologies and systems, demanded new approach in terms of reports, records and accounting analysis. This development is the engine of the changes produced in the

achievement, presentation and use of accounting information and accounting knowledge.

This is the explanation for the increase in the intensity of the organization's concerns to design, develop and implement information systems that take advantage of modern technologies and support the decision-making process according to the current requests of the business environment.

Although the forestry area has a particular note, being an area governed by special laws, enjoying a diverse and complex range of activities, the forest management is also aligned to the new trends in the sphere of economic decision assisted by accounting knowledge.

Some of the latest developments and researches on information systems of organizations are using, as their center, the knowledge bases to assist the decision. Often, in the process of designing knowledge based systems, the modeling act plays an important role.

A real support for integration and representation of models in information systems engineering process, can be offered by ontology construction.

In this paper we intend, after reviewing the literature in this area, to form an opinion regarding the necessity and importance of using ontologies in forestry accounting information systems design.

2. Foray into the concept of ontology of information systems for business

In our approach we started considering the exciting game of words, according to whom, the ontology identifies what needs to be shaped by information systems and, at the same time, the ontology can provide a basis for modeling the information system itself. [28]

Over time, many researchers have had the concern to establish a meaningful definition of "ontology".

J. Hendler [13] defines ontology as a set of terms of knowledge through which the author recalls: the vocabulary, the semantic interconnections and some simple rules of inference and logic for specific topics. Other approaches to the ontology concept refers to the ability they have to accomplish specifications of communication between multiple agents in the form of a shared vocabulary, [20] and to be used in modeling. [14]

Regarding the use of ontologies in knowledge management, Jurisica, I., Mylopoulo, J., and Yu E. [15] note that there are the following four categories:

- static ontology;
- dynamic ontology;
- intentional ontology;
- social ontology.

In their survey, the three mentioned authors underline that the identification of concepts that are able to accomplish the computer modeling process (operating in knowledge management), is the subject of ontology, viewed from the perspective of information systems engineering.[15]

Using ontology can improve, as Gălătescu and Greceanu said, the team effort to achieve business increase, because:

- It provides a common vocabulary to the team members;
- It makes automated comparisons;
- It integrates verbal diagrams and structures with ideas;
- It provides to the user an extensible interface [11].

According to several researchers [2], [10], [21], [29] the objective specification, which ennobles the information using ontology, represents ground zero in constructing a business semantic model to be used in designing the appropriate information system.

Noy and Klein [18] reviewed the similarities and differences that exist between database schemes and ontologies. Among the differences observed, there were listed:

- different ways to use the paradigms;
- explicit semantics;
- modeling knowledge differently.

Differences were observed between ontologies and conceptual schemes by Fonseca and Martin [8] as follows:

- they belong to different epistemic levels;
- they have different objects, but different objectives, too.
- ontologies explain and integrate the information, while conceptual schemes, link together general ontological categories to specific observations.

De Cesare and Lycett [7] even propose a modeling language, Unified Modeling Language (UML), to achieve business profile ontology definition.

In a study on dynamic modeling of the enterprise, for organizing the planning and control, [6], Church and Smith give reasons to support the hypothesis that a dynamic model based on ontology allows managers an optimal estimate of the consequences of resources allocation decisions, but also the determination of the appropriate performance indicators.

Another approach, on rules based analysis needed in the economy, which aim to share the information system domain in subdomains stakeholders oriented, was led by Bogdan and Păduraru [5].

In terms of marketing activities involving the exploration of large databases (DBM), too, the definition and use of ontologies have advantages [23]:

- provide a set of options for defining activity of DBM;
- suggest best approaches in terms of DBM objectives;
- guide the selection of relevant data;
- achieve specification of constraints for the selection of data mining algorithms.

Relevant classes of users of ontologies, for financial control in the accounting profession, as they were listed by Tiron-Tudor et al. [26], are:

- financial professionals;
- police and other statutory supervisory agencies;
- control and economic supervisory bodies;
- multinational companies and groups of companies;
- independent experts and professional bodies.

In their paper [1], Andersson et al. have presented a reference ontology for business modeling that is based on three ontologies of the business:

- *Resource-Event-Actor (REA)*, which originates in enterprise accounting;
- *e³ value* which identifies the changes that the objects' values have among the actors involved in the business;
- *Business Model Ontology (BMO)*, which performs in-depth description of the company's business model.

The goal of this reference ontology construction was to increase the understanding of the three ontologies, but also to develop a tool which can forward models from one formal system to another.

Geerts's studies [12] underline the conclusion that operational enterprise ontologies give a shareable and reusable support to the business specific applications, to maintain flexibility. XML (eXtensible Markup Language) technology is proposed to achieve ontology.

The proposal made by Funk et al. [9], in order to achieve the best possible resultant integration of separate information extraction tools and to improve accuracy of this process is an information mining system for business intelligence, using a *de facto* "standard" web ontology: *Proton*.

The study conducted in 2010 by Mangiuc [16], shows how the use of UML can improve the definition, description and representation of *Semantic Web* type enterprise ontology.

3. The ontology of forestry systems

During the World Forestry Congress in 2009, Petrokofsky and Mills [22] have emphasized that experts in computer and library should have the duty to ensure the forestry researchers, practitioners and policy makers, that they make decisions based on the best-organized existing records, systematically collected through basic research. A proposal was launched to create a pilot forum for discussion on this subject, in the *International Union of Forest Research Organizations 6.03 unit, Information Services and Knowledge Organization*. This emphasizes the increased role of information specialists.

Tochtermann and Maurer [27] have conducted a literature review in which they concluded that the application of ontologies in environmental informatics calls for ontologies adjustment to different

characteristics of specific data (ex.: temporal, geographical, thematic or organizational relations).

Since forestry, par excellence, is dedicated to sustainable projects, it has come to our attention the work done by Bodea et al. [4], which presents an ontological model of commercial projects for sustainable development. Ontological approach (with the support of ontology called *PMCatalog*) is related to a skills model in management projects.

In forestry, a major concern is the forest management plans and forest inventory accuracy. To ensure these requirements, was developed *FIM* (Forest Inventory and Mensuration) ontology, a possible web-service for *FMA* (Forest Model Archive) [25]. This was the solution to the "Achilles' heel" in terms of forest inventories centralization systems: incompatible data.

Forest Information Service (*FIS*) has become a focal point for many organizations such as the European Commission and IUFRO [24]. *FIS* nomenclature, it says in the cited paper, must be consistent and shared. This goal can be achieved by developing a European decision support system centered on the *FIS*. For this purpose, it is proposed the use of ontology languages such as: *DAML*, *OIL* or *OWL*.

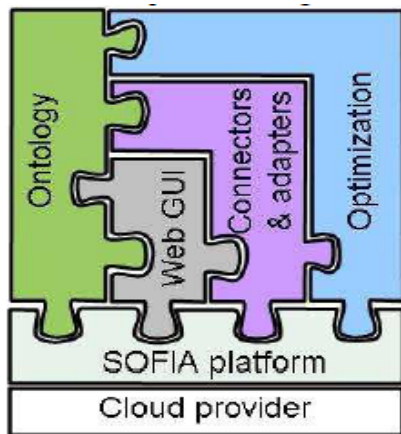

NED2 system is a goal-oriented intelligent system for forestry decision making, integrating databases, growth and yield models, wildlife models, silvicultural expert systems and geographical information systems, developed by a group of American scientists [19]. They considered a prerequisite, for the establishment and development of the system architecture, the use of a robust ontology, which supports communications between *NED2* and a variety of forest management decision assisting tools.

Information communication technologies within the organization or between organizations in the Australian timber and logging industry are analyzed by Blake [3]. The cited dissertation work shows us new ways of building the ontology of the domain first stage. Among the variables used for the exemplification, *Price* and *Discounts* are included.

Nikitin, Terziyan and Lappalainen [17] believe that the platform SOFIA (Seamless Operation of Forest Industry Applications) is suited for worldwide forestry market. SOFIA is a software platform for logistics integration optimizing, characterized by flexibility and extensibility. It can provide, according to the authors, a sustainable infrastructure as information and communication technology, for small and medium logging and transport firms.

Developing a SOFIA platform, ontology is considered the "backbone", a rich configuration file that describes the structure of software components set in motion in the same way as data, as shown in Figure 1.

Figure 1. SOFIA component view

4. Conclusions

A large number of researchers have been interested in the study of ontologies for a wide range of areas.

According to the business information systems researchers, the benefits that the use of ontologies makes in the design of these systems are:

- optimization of integration;
- extensible interface;
- common vocabulary provided;
- objective specification of information;
- facilitating the sharing and reuse of information.

For forestry information systems, the use of ontologies has proven to be beneficial in solving a thorny problem: incompatible data. The requirements for the ontologies in this

area are: robustness, flexibility in communication and interconnection, extensibility.

There are already a large number of languages for the computer assisted design of ontologies: XML, UML, DAML, OIL or OWL.

Conducted studies strictly in forest accounting information systems ontologies could not be identified. Current trend is to integrate these solutions within complex and unitary systems that can bring together all the information and knowledge necessary for such organizations.

We conclude that, due to the many benefits of their use in designing accounting information systems, ontologies are very necessary in this process.

The CR-Marketing Strategy

Pricop Oliver Constantin

"Petre Andrei" University of Iasi, Faculty of Economics

opric24@yahoo.com

Abstract

The Customer Relationship- Marketing supposes the adaptation of the marketing mix from the customers' and the market's perspective. Thus, the 4 P (product, price, place, promotion) must become 4 D (desired by consumers, distinctive from the competition, deliverable by the company, durable over time) respectively 4C (the buyer with his requirements and desires, the cost paid by the buyer, the convenience of the acquisition, the communication with the customers. The CR-Marketing strategy comprises the customer acquisition strategy, the customer engagement strategy, the customer recovery strategy, the competitive advantage strategies.

Key words: customer relations marketing, customer perspective, customer acquisition, customer engagement, customer recovery.

J.E.L. classification: M 31

1. Introduction

CR-Marketing (Customer Relationship-Marketing) is not a new concept from the point of view of its content, but what it lacks is its integration into a strategic marketing vision which confers it applicability principles and specific objectives. The customer relationship has become the central preoccupation of the marketing activity ever since the moment of the marketing optics development. Few organizations understand however this relationship in an integrated approach, the majority being limited to the sale process, to the service and follow-up customer monitoring and to the public relations activity. What this concept is attempting is to particularize the Customer Value Management in the marketing sphere [1] and to integrate marketing more

distinctively in the Corporate Social Responsibility .

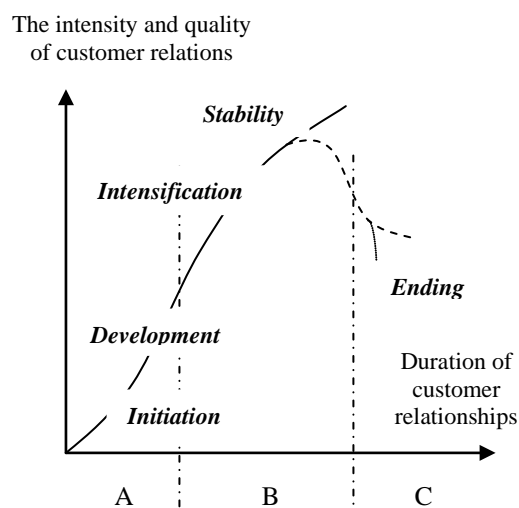

2. The CR-Marketing Strategy

CR-Marketing "thematizes the entire life cycle of the customer relationships in a company, placing to the fore the mutual benefit for the partners from the relation"[2]. The characteristics of this concept are [3]:

- the durability in time of the customer relations;
- achieving a continuous process for building the relationship with the customers materialized in acquiring customers, their engagement and recovery;
- customer dialogue;
- customer value.

The first two characteristics are strongly connected and can be analyzed through the life cycle of the relationship with the customer which is presented in the following manner:

Figure 1. The life cycle of the customer relationship

Source: Bruhn, M., *Relationship Marketing. Das Management von Kundenbeziehungen*, München, 2001, p.48.

A - Customer acquisition:

- initiation phase
- socializing phase

B - Customer recovery:

- danger phase
- dissolution phase
- abstinence phase

C - Customer recovery:

- danger phase
- dissolution phase
- abstinence phase

In order to implement the CR-Marketing vision, the marketing philosophy centered on the 4 components of the marketing mix must be adapted from the perspective of the customers and the market.

Thus, the 4 P (product, price, place, promotion) must become 4 D [4] (desirable by customers, , distinctive from the competition, deliverable by the company and durable over time) respectively 4 C [5] (the buyer with his requirements and desires, the cost paid by the buyer, the convenience of acquisition, the communication with the customers.

The correspondence relation between the 4 P and the 4 C, respectively the 4 D can be achieved in the following manner:

Table 1 . The correspondence between the 4P and the 4 C, respectively the 4 D

Product (1P)	The buyer's requirements and desires (1C)
	Desired by consumers (1D)
Price (2P)	Cost paid by the buyer (2C)
	Distinctive from the competition (2D)
Place (3P)	Convenience of acquisition (3C)
	Deliverable by the company (3D)
Promotion (4)	Communication with customers (4C)
	Durable over time

The product politics must be achieved from the customers' perspective, taking into account what they want and their requirements. The price politics must be configured so that the cost can be paid by the consumer and at the same time lead to a clear difference compared to competition. In the placement politics, the companies must prove

that they know the markets and must prove realism towards the efficiency of their own capacities or attracted by distribution. At the same time, it must offer consumers accessible and effortless solutions for acquisition. The promotion politics must be centered on the strong communication with the customers and on the transformation of this product in a long-term partnership relationship.

As we can see in the figure below, the marketing strategy is composed of the 4 P which must in their turn be reconfigured in the 4 C, respectively 4 D with whose help the CR-Marketing is formulated, which lays at the basis of the marketing strategy. This cyclic product manages to adjust the marketing strategy from the customers' perspective.

Figure 2. The CR-Marketing integration into the marketing strategy

The CR-Marketing strategy comprises the following sub-strategies [6]:

- the customer acquisition strategy supposes the identification and attraction of customers towards the company's offer
- the customer engagement strategy involves the customers in the process of offer design and achievement so that the loyalty towards the company's offer and its vision of making business be at its utmost. This strategy has a dynamics divided in three directions : satisfying the customers' expectations, building the customers' loyalty and involving them in the process of value creation.

- *the customer recovery strategy* is used either for reactivating the latent customers or for recovering the customers lost in favor of the competition. Most of the times the strategy supposes rebranding or repositioning actions.

- *the competitive advantage strategies* aims at identifying the elements of competitive differentiation from the consumer's perspective within the marketing mix. A model of adapting the differentiation competencies from the consumer's perspective in relation with the bidder's perspective may be achieved as below:

Table 2. The competences associated to the differentiation mix

Potential competitive advantages from the company's perspective	Competitive advantages in relation with the consumers' perception
Product: - the diversity of the product range - the performances of the product characteristics - the value of the product package - the trademark uniqueness - state of the art service operations	Product: - opportunities of satisfying different needs - reliability and utility of the product - quality of protection, facility of identification, manipulation, uniqueness of design etc. - easy information, social and psychological benefits - service availability, rapidity and quality
Price: - competitive offer price - significant discounts and advantages - convenient payment conditions	Price: - price variants – purchase power – quality Available to all the categories of consumers
Distribution: - high degree of logistic equipments - advantageous localization of deposits	- possibility of having a supplementary income or of paying less - favorable payment conditions for any category of consumers

- reduced distribution costs Personnel: - highly qualified personnel - available and nice sales personnel - consultancy services Promotion - responsible communication - company's reputation - quality public relations - use of the most efficient means of communication	Distribution - high quality of deliveries, safety of merchandise - rapidity at delivery, optimal market coverage - synergic commercial efficiency of the distribution network Personnel - high quality of products and services - promptness and consistency in serving, connected information, acquisition without stress or difficulties - quick information of consumers and quality solving of their potential problems Promotion: - real and opportune information - trust in the company's products/services value Relaxed atmosphere, availability of information Use of the communicational mix capable to inform efficiently all the segments of consumers
--	--

Source: Pricop, O.C., *Marketingul valorii concurențiale, prin preț și prin diferențierea produselor*, Junimea Publishing, Iași, 2006)

- *the strategies of customer focusing* which are of two types: the strategies of market processing and the strategies of relation processing. The strategy of market processing supposes the adaptation of the sales and distribution processes to the customers' needs. Moreover, the price level is particularized on categories of clients. The strategy of relation processing supposing adjusting the customer relationships in favor of satisfying their needs. The consumer is advised and asked about the level of the consumer satisfaction in all its three moments: pre-purchasing, purchasing and

post-purchasing. It is important to determine in this sense the degree of customer satisfaction during the purchasing process.

The consumers' degree of satisfaction (Gsat) can be divided in the following sub-indicators [7]:

- the degree of satisfaction before the purchase which estimates the consumer's expectancy level (lack of patience) to acquire the product (Gsa);

- the degree of satisfaction since the purchase moment, which measures the level of satisfaction in the moment of the contact with the product (Gsc);

- the degree of satisfaction in the consume/use moment (Gsu);

- the degree of post-use/consume satisfaction which helps assessing the extent to which the product consume/use increased the individual's standard of living/satisfaction. (Gspu).

Each sub-indicator is assessed with the help of a scale with three stages, each stage having a score comprised between +/-1:

- for Gsa: interested (+1), indifferent (0), not interested (-1);

- for Gsc: satisfied (+1), indifferent (0), unsatisfied (-1);

- for Gsu: satisfied (+1), indifferent (0), disappointed (-1);

- for Gspu: satisfied (+1), indifferent (0), unsatisfied (-1).

Since from person to person these moments from the acquisition process have a different importance in estimating the degree of satisfaction, the above-mentioned sub-indicators must be balanced with the help of certain importance coefficients with values comprised between 1 (minimum values) and 4 (maximum value) and which we will note with letters from "a" to "d".

The degree of satisfaction will be calculated with the formula:

$$Gsat = a \cdot Gsa + b \cdot Gsc + c \cdot Gsu + d \cdot Gspu$$

The individuals questioned will indicate a certain level for each sub-indicator, with the possibility of resulting negative, null or positive Gsat values.

- if $G_s < 0$ the good purchased produced lack of satisfaction, being very little probable that the consumer will repeat the acquisition, in the near future.

- if $G_s = 0$ the good did not produce satisfaction, the probability of repeating the acquisition being accidental.

- if $G_s > 0$ the good produced satisfaction, having great chances of being purchased in the future.

With the help of this indicator, by analyzing the conception or marketing deficiencies of goods/services and sale activities, the company can better protect its competition advantages and can discover easier the opportunities of penetrating the markets held by competitors.

3. Conclusions

Therefore, the Customer Relations marketing represents, together with creative marketing, the most recent tendency in the modern marketing. What this tendency is lacking is the operational content integrated at the level of all the behaviors and structures of the organization. The adjustment of the politics composing the marketing mix based on the model presented can be a solution in this regard. This demarche will lead to the real consumers' approach towards the organization and to the creation of a partnership relationship, partnership achieved by creating certain consultancy structures of the customers affiliated to the organizations. Thus, we will be able to speak in the future about CP-Marketing (Customer Partnership Marketing).

Comparative Analysis between the Economies of the Euro Area and the USA

Puiu Cristina

puiu.cristina@yahoo.com

Abstract

Differences in economic performance between the USA and the euro area have been the subject of much debate. Even though these large economies might be considered similar, there can be identified some differences. This paper aims to realize a parallel between two of the largest monetary unions in the world. To compare the economies of the currency unions in Europe and United States of America I have chosen a set of indicators regarding monetary policy, growth and financial markets. The answer provided by the analysis is that the Euro Area has made an impressive progress since its initiation, but this has to be continued in order to achieve the performances in the USA.

Key words: euro, currency unions, USA, monetary policy

J.E.L. classification: E42, E52, F15, F33

1. Introduction

The euro area and the United States of America are two of the greatest economies in the world, with over 600 millions habitants and responsible for approximately 40% of the world output. The preponderance of these two regions and their similar dimensions determined the interest for comparative analysis.

The United States of America represents a monetary union approximately similar with the Economic and Monetary Union in Europe in terms of dimension. In 2010, the population of the USA was around 310 million persons and the GDP was more than 14 trillion dollars, comparing with the population of 330 million and the GDP of more than 12 trillion dollars persons in the

euro area.

The origins and the development of a monetary union in the United States are very different from the conditions of introducing a single currency in Europe. While the institutions of the Economic and Monetary Union developed in a short period of time, those in United States have evolved in stages from the introduction of the dollar in 1792. The monetary union was created formally in United States at the same time with Constitution's ratification in 1788. However, USA has accomplished the characteristics of a complete monetary union, a central bank and a single currency, in the next 150 years. The institutions of a monetary union in the USA have evolved as an answer to certain needs or difficulties and not according to a preordained framework.

2. Main economic indicators

The position of the euro area as the second monetary area in the world taking in consideration its dimension, after the United States of America, has triggered many comparison analysis regarding the economic performances of those two.

Monetary policy

The monetary policy conducted by these two unions is differentiating by three aspects: the inertia of the monetary policy, monetary policy objectives and monetary policy strategy. [6]

Regarding monetary policy inertia, it has been considered that it is higher in United States. This fact can be observed by comparing the evolutions of monetary policy interest rates (figure 1). However, the apparent difference between the inertia of the monetary policies conducted by these two areas represents the consequence of different macroeconomic shocks, especially due the fact that the USA has been confronted with higher demand shocks than those in euro

area.

It is considered that the transmission mechanisms are different in these two monetary areas, being less powerful in Euro Area than in the USA. As a result, it can be thought that ECB should act more decisively and faster than the FED.

The comparison of changes in the two central banks' interest rates reveals greater inertia in the eurozone. The fed funds target has been lifted higher and cut lower since 1999 than the ECB's refinancing rate, varying from 1% to 6.50% since 1999 compared with a range of 2% to 4.75% for the ECB.

This could appear like a less active policy in the eurozone, but it has not prevented growth and inflation varying by less than in America. Therefore, what looks like inertia partly reflects differences in economic structures and macroeconomic shocks, with greater reactivity in the USA. It might not be entirely attributable to fundamental differences in the nature of the two central banks. [3]

Figure 1. Central banks' interest rates in the USA and the Euro Area

Source: [4]

Regarding monetary policy objective, the FED seeks to “promote effectively the goals of maximum employment, stable prices, and moderate long term interest rates”. From this statements results that FED has to pursue the objectives of growth and price stability, while the ECB gives priority to price stability. Thus, the FED is given greater flexibility but it must get its priorities right when interests clash between growth and price stability.

Some economists consider that the difference between the unique objective of the ECB of maintaining price stability and

the dual objective of the FED regarding price stability and full employment should not be over evaluated. Indeed, even Alan Greenspan and Ben Bernanke have admitted publicly several times the fact that maintaining price stability is the best contribution that monetary policy can bring to promote the objective of a sustainable economic growth.

Regarding monetary policy strategy, there can be identified many differences, among which two are more important. First refers to the fact that, unlike the FED, the ECB took the commitment to monitor and, if is necessary, to react at monetary supply and credit evolutions, taking into account the strong association between this and the inflation level. The role of money is much more prominent at the ECB than at the FED. The second difference is that the ECB accentuates the stabilization of inflationary expectations.

Inflation rate in the United States of America was in almost every observed year higher than the inflation in euro area. In 2009, the inflation went to negative values, being lower than the one registered in the euro area.

Figure 2. Inflation rate

Source: [4]

Inflation differentials between countries in the euro area have diminished and presently they are similar to those registered in the USA. In the United States – an old monetary union – starting with 2004 inflation rate dispersion between the 14 metropolitan statistical areas has fluctuated close to the levels for the euro area.

Growth

The economy of United States maintains its supremacy regarding the production dimension. Euro area comprises seventeen

states of which cumulate economic importance does not surpasses the one of United States, remaining on a second place.

Recent evolutions show that euro area tries to gain ground. Starting with 2006 and until 2008, gross domestic product growth surpassed the one of America. One possible scenario for equalizing the United States is that Great Britain, Denmark and Sweden adopt the single currency.

Figure 3. Real GDP growth rate

Source: [4]

For a long period of time, low unemployment rates made the United States of America a model for the rest of the economies in the world. Organization for Cooperation and Economic, International Monetary Fund and other international organizations commended the performance in terms of employment of the USA.

Current economic crises affected the workforce situation in the USA. According to most recent standardized data at international level, the USA is on the fourth place among big countries of OECD, considering unemployment rate level.

Figure 4. Unemployment rate

Source: [4]

As it can be observed from the previous figure, in 2009, for the first time since the beginning of publishing data by Eurostat, unemployment rate in USA was almost the same as the one in the euro area countries.

In March 2009, unemployment rate in USA has been 8.5%, lower only than Spain, Ireland and France and at the same level with Portugal. [8]

Another specific feature regarding unemployment rates in these currency unions is that unemployment rises first in the USA then in the EMU. US unemployment began to rise in the spring of 2000; the euro area followed a year later. The 2003-2004 peaks were even more than a year apart. More recently, US unemployment stopped falling in late 2006, while euro area unemployment continued its unexpectedly rapid decline until late 2007. Even the increase in unemployment in 2008 started first in the USA and then in EMU.

Current account

Regarding current balance, it can be observed in the figure 5 that United States deficit is very high, especially compared with euro area. This feature depends on the policy of the underlying asset issuer, precisely of the USA policy since the main reserve asset is the American dollar. In 1960, Triffin underlined the fact that the existence of low deficits of the USA can create liquidity problems and recession and that high deficit can alter American dollar stability. Currently, the volume and the volatility of capital flows create a potential tension between the willing of countries to accumulate reserves to protect against capital flows overflow and worries regarding the fact that reserve active supply depends solely to one country.

Monetary policy relaxation in the USA and credit deduction in price have taken to the growth of public money used for current account operations, especially imports, determining the maintaining of high current account deficits in USA. Simultaneously, current account deficits have made possible for the USA to supply dollar denominated assets that the rest of the world needed in order to protect against high and volatile global capital flows. Particularly, countries that have been confronted with capital inflow have wanted to accumulate dollar reserves to protect of possible sudden flood of these inflows. Thus, the pressure that the USA

functions with large current account deficit was relatively high. [2]

Figure 5. Current account balance

Source: [4]

The current account deficit of the USA has diminished from 4.9% in 2008 to 2.9% of GDP in 2009, respectively half of the level registered in 2006 (when have been registered most accentuated unbalances in absolute terms). Overall, current account deficit has been strongly reduced from 4.9% of GDP in 2008 to 2.9% in first three quarters of 2009, especially due intern demand reduction and lowering petroleum prices.

Public finance situation

It is well known that one important criteria of the euro area stability is the soundness of the public finances. The Eurozone comprises a single currency in combination with fiscal policies conducted at national level – albeit within a common framework – by its participating Member States. This is unlike federal monetary unions, like the United States, where a federal government is endowed with sovereignty to tax and to provide common public goods. The US federal budget acts as a powerful stabilizer, enabling fiscal transfers to automatically flow from booming to slumping states, whereas the euro area has no such transfer mechanism.[11]

Regarding fiscal policies, it can be observed from the next figure that public budget situation was better in USA in 1999-2001, after which followed a deepening of budgetary deficit higher than the one registered in the euro area. Recently, the gap between those two deficits became higher. In SUA, the strong deficit reflects the strong

diminishing of incomes, caused by reduction of taxes receipt and substantial expansion of public expenses, following fiscal measures meant to support the financial system and the economy.

Figure 6. General government deficit/ surplus

Source: [4]

The share of public debt in GDP was higher in the euro area comparing with the United States of America in 1999-2009 periods. Economists consider that bringing public debt share at lower levels it will be difficult for the United States. Taking into consideration the high public deficit and the high and growing levels of debt, there are necessary strong efforts for consolidation in order to change the growing trend of these weights. [5]

Figure 7. General government debt

Source: [4]

The yield of governmental bonds had in 1999-2010 range similar values.

In 2008, there have been registered higher values for the governmental bonds yields, situation unrecorded since 2003. At the end

of 2008, the yields of long term governmental bonds in the euro area and the United States have been approximately 3.6% and 2.2%, being lower than the levels from the previous year with 75 base points and, respectively, 184 base points.

Figure 8. Government bond yields, 10 years' maturity - Annual data

Source: [4]

The yields of the long term governmental bonds in the USA have marked a powerful decline at the end of 2008, thus at the beginning of 2009 these have been situated at the lowest levels in the last forty years.

The fact that bonds yields have been situated at the lowest levels compared with historical averages has been determined by the ample cuts of the monetary policy interest rates, adjustments in a descending way of market participant regarding inflationary risks and of the massive reorientation of investors to the public bonds, in the detriment of risk assets.

Pronounced increase of the yields of the titles in the United States conducted to the switch of yields of governmental bonds in the euro area and the United States registered at the end of 2008, thus, the yields corresponding to ten years governmental bonds in United States have positioned at higher levels than those in euro area in the last part of 2009.

During 2010, long term government bond yields decreased in both areas, remaining lower in the USA than the euro area.

The analysis of the economic situation in the euro area, comparing with the United States is important even from the perspective of the fact that this represents one of the features considered in establishing the role of the euro as an international currency against the American dollar.

3. Conclusions

The dimension of the monetary union in the Europe attracts numerous comparisons with the monetary union in the United States of America. The performances of those two monetary unions somehow resemble. From the introduction of the single currency, the euro area registered better evolutions comparative to the USA only regarding inflation level, current account balance and budgetary deficit, having to recover at the level of unemployment rate, productivity and public debt situation.

Rose Effect: How Far Can it be Argued that the Euro Increased Trade?

Puiu Cristina

„Alexandru Ioan Cuza" University of Iași, Doctoral School of Economics
puiu.cristina@yahoo.com

Abstract

Current imbalances in the euro area made it necessary to identify the benefits of a single currency in order to sustain the viability of it. This paper aims to review existing literature on the endogenous effects of monetary integration: whether sharing a single currency may bring countries closer together through an increase in trade. The first part is a review of significant paper in the vast literature on the endogeneity of optimum currency area theory that focuses on the main criterion that is subject of this hypothesis. The second part considers empirical literature on the effects of monetary integration on trade based on evidences provided by the euro area experience.

The main conclusion is that the hypothesis attracted a large number of studies and, although they provide heterogeneous results caused by using different methodologies, they all indicate a positive effect.

Key words: optimum currency areas, endogeneity, euro, Rose Effect

J.E.L. classification: E42, F15, F3

1. Introduction

The theoretical framework for analyzing monetary unions is provided by the Optimum Currency Area Theory. This was first introduced by Mundell (1961) and became known especially thanks to the cost-benefit analysis of monetary integration. Thus, the theory sustains that the advantages of joining a currency area depend on the capacity of the member countries to form an optimum currency area.

The creation of the European Monetary Union stimulated the interest in theoretical and empirical research on optimum currency areas and it is considered that the latter

contributed to the foundation of the single European currency.

Professor Ronald Mckinnon proposed one of the economic criteria, the degree of economic openness. According to this, countries which are more opened to each other could form a monetary union since renouncing at the exchange rate as an adjusting instrument for asymmetric shocks would not be costly.

One of the most important recent developments in the literature regarding optimum currency areas is represented by the analysis of how the creation of a currency union can affect the factors that influence the well functioning of it. The endogeneity problem of monetary integration can be explained by observing the fact that sharing a common currency by many countries can bring them closer together. These considerations have been captured in the endogeneity hypothesis of optimum currency area criteria.

The theory of optimum currency area endogeneity was first introduced by Frankel and Rose, who sustained the idea that countries joining a monetary union can satisfy the criteria ex - post, even though they are not fulfilled ex - ante [11]. Thus, according to Warin, Wunnava and Janicki ([21]), examining historical data gives a wrong image about the right moment to join a currency union since the criteria are endogenous. The argument brought by those two authors is based on the experience of the first wave of participants to the euro area which showed that some criteria for a successful monetary area, like trade openness and business cycle convergence, are endogenous.

This analysis should be regarded carefully because the degree of endogeneity can be exaggerated, some taking it too far by suggesting that almost any currency union can become optimal [22].

2. Criteria of the endogeneity hypothesis

The rich literature on the endogeneity of optimum currency area started with the article of Rose and Frankel (1997). Concentrating their analysis on trade integration they have showed that it increases significantly once a currency union is created.

With this paper, the authors have opened a series of debates on optimum currency areas, showing that the introduction of the single currency in an area can help to fulfill criteria ex-post even though they were not fulfilled ex-ante. Frankel and Rose analyzed business cycles and the trade intensity of twenty industrialized countries between 1959 and 1993 and found a positive relation between these two criteria. However, their analysis is based on non-euro data.

At the end of the paper, the authors sustain that this represents only the application of "Lucas's critique" to the optimum currency areas analysis, arguing that trade flows between states influences the business cycle synchronization since both criteria are affected by policies. According to the analysis of Silvestre and Mendonca ([20]), this shows that business cycles of the countries belonging to an optimum currency area are affected after integration by a centralized monetary policy and by an increase in trade flows.

Recent studies show that, before formulating the hypothesis of endogeneity by Frankel and Rose, this was intuited by the founder of the optimum currency area theory, Robert Mundell. The work of Warin, Wunnava and Janicki ([21]) brings to attention a less known article of Mundell that sustains the fact that risk division is optimal when countries fulfill a great degree of heterogeneity. This article represents an improvement, if not a correction of the optimum currency area theory, initiated by Mundell in 1961. Until this paper, Mundell argued that an economic area must be optimal before sharing a single currency or a fixed exchange rate mechanism. The causality has been reversed in 1973 since the sharing of a single currency or the participation on a fixed exchange rate mechanism can help an economic area become optimal. Thus, there is a precedent

for the endogeneity of optimum currency area theory (formulated by Frankel and Rose in 1997) represented by Mundell's intuition from 1973.

The endogeneity hypothesis of optimum currency areas is the opposite of the specialization hypothesis formulated by Krugman [15]. The latter appears illustrated in the work "Lessons of Massachusetts for EMU" where they use the example of the economic evolutions in USA from the last century. Based on this, the author considers that it will be specialization in the euro area countries and, thus, they will be more vulnerable to specific shocks.

Akiba and Iida [1] have sensitized the results of Krugman's work and showed that, as countries become more integrated, their reciprocal volume of trade increases (a macro-economic sufficient condition for the OCA), implying an increase in the degree of fulfilling the criteria. The increase of openness encourages specialization of production in commodities, for which the exporting countries have a competitive advantage and this determinates the undermining of the necessary condition for an optimum monetary area. Countries in a monetary union are vulnerable to asymmetric shocks because the correlation coefficient of the outputs tends to fall.

Frankel combated the anti-synchronization hypothesis of Krugman by emphasizing the fact that a great share of the current trade is in inputs and intermediate goods, therefore it leads to a positive cyclical correlation [12].

Later on, there have been discovered other sources for the optimum currency area theory. Many authors brought concept similar to the ones already mentioned, but in other fields than trade. Mongelli (2008) examined three additional sources of endogeneity, as:

- the endogeneity of financial integration or the equivalent of insurance schemes;
- the endogeneity of symmetry of shocks and synchronisation of outputs;
- the endogeneity of product and labour market flexibility [17].

3. Empirical results regarding trade effect

Endogeneity hypothesis launched by Frankel and Rose has been followed by a series of empirical studies considering the

impact of joining a monetary union on trade and business cycle synchronization.

Professor Andrew Rose from California-Berkley University opened a new chapter in the international economy research with an article published in 2000. He addressed a simple question and got a simple answer: What effects has a single currency on international trade? The answer: big. The model used represented a naive version of the standard gravity model and found that trade approximately triples among countries that share a common currency, after controlling for exchange rate volatility. The idea of Andrew Rose that monetary union can contribute to trade expansion within euro area lead to the formulation of "Rose effect" concept.

The results of Rose study showed that the effect of a monetary union might be different from the effect of reducing volatility. Taking into consideration that a common currency is a much more robust commitment than a promise to reduce exchange rate volatility or even a currency board arrangement, it might be expected to have non-linear effects. This can be illustrated in the figure 1 below.

Figure 1. Exchange rate volatility and trade

Source: [17]

From the previous graphic it can be observed that the non-linear relationship is illustrated by the solid line, while the linear exchange rate volatility term in a regression captures the relationship given by the dashed line. Thus, the addition of a common currency dummy to the linear volatility term might be showing up as the "Rose Effect".

The effect on trade of the single currency estimated by Rose was too high to convince many economists, fact that brought him many critiques. Such large estimates generated significant interest and researchers began the "Shrink the Rose Effect" effort [8]. Some of the critiques were grouped by Baldwin into three categories:

- omitted variables (omitting variables that are pro-trade and correlated with the CU dummy biases the estimate upwards);
- reverse causality (big bilateral trade flows cause a common currency rather than vice versa); and
- model misspecification [4].

A recent analysis conducted by Frankel ([13]) identifies five sources for the skepticism regarding Rose (2000) results. Two of them can be found in those formulated by Baldwin: omitting some factors and the endogeneity of choosing the currency [2].

A new critique is related to the fact that the evidences obtained at section level do not necessarily lead to the real time affect obtained by the countries who adopt a single currency. Also, Frankel sustains the fact that the estimated effect on trade is too high to be credible. The arguments brought by other authors, related to choosing the parameters and to the fact that the real effects are more reduced, seem to sustain this critique.

Finally, the last critique refers to the fact that Rose evidences are obtained after analyzing countries that were small or very small. Thus, it was not so clear that the estimations could have been extended to bigger countries. The economies in euro area tend to be large, very large, while the countries outside the area tend to be small, some of them even very small.

Rose (2000) paper regarding the impact that unions have on trade has been followed by many studies.

Micco, Stein and Ordoñez ([16]) have realized the first published study that applies Rose techniques to euro area. The authors used the gravitational model of bilateral trade, taking into consideration the fixed effects of countries pairs and using annual data for 1992-2002 periods. Based on different regressions, the authors have estimated that the single currency effects on trade inside euro area ranged between 4 and 16%.

Flam and Nordstrom ([9]) have introduced a number of innovations that corrected some standard econometrical mistakes in the literature. Their main results on aggregate data are similar to those of Micco, Stein and Ordoñez (2003), in matters of size and synchronization. They have used countries outside euro area and eight other additional countries with high income as a control group and obtained as a result the fact that Rose effect implies approximately a 15 percent higher trade; the volume of trade between euro area countries and other countries is raised with half of the previous mentioned value. Using the clearest definition of the control group, the Rose effect is only 9 percent. Findings on sectoral data show that Rose effect is found only in the sectors with differentiate products.

The work of Flam and Nordstrom ([10]) revised the 2003 study by using more recent data. Moreover, they have offered estimations of Rose effect on components trade in opposition to the final goods trade, for studying the possibility already indicated in 2003 that euro currency encourages production fragmentation. This study shows that the "Euro Effect" is increasing over time. While for their 1989-2002 dataset is 15%, for 1995-2005 data is about 26%.

Bun and Klaasen ([6]) represents an actualization of the paper wrote in 2002. Unfortunately, the results are destroyed by the „silver medal" mistake. This is kind of surprising because the previous paper, Bun and Klaasen (2002), is one of the few studies that have avoided this mistake. At the beginning of the paper they have reproduced the results from previous literature by estimating the euro's effect on trade between 51% and 18% for data sets from 1997-2002, 1992-2002 respectively. After including the trends, their estimations dropped to 3 percent and 2 percent respectively.

De Nardis, De Santis and Vicarelli ([7]) also improved their previous paper from 2003, the central point of the new one being represented by the application of the dynamic study in estimating euro's effects. Unfortunately, their results are difficult to interpret since their work is marked by the Anderson-van-Wincoop wrong interpretation, which is very common in the literature. This paper shows a euro effect about 4-5%.

A less known paper is the one of Gil-Pareja, Llorca-Vivero and Marinez-Serrano ([14]), which uses the gravitational model based on data referring to 25 OECD countries in 1950-2004 periods for estimating euro's effect on trade. The problems found in used methodologies are high lined by the obtained results. The main estimations show a euro effect between 38% and 71%.

As Baldwin mentioned about the literature before the introduction of euro, such high estimations lack of credibility [2]. If the trade between the countries who used euro would have increased in 1999 with 60-70% over the one of the other EU countries who had not adopted euro, there would not have been needed special econometrical studies to detect this growth. The effect would have been obvious since the rest of the factors which determined the trade was not different in euro area compared to the rest of the countries from EU5 group.

Baldwin identified the main critiques as the gold, silver and bronze medal for gravity equation mistakes. The gold medal is for omitted variable bias; the silver is for using the average of exports and imports and the bronze medal is for deflating nominal trade variables by US CPI inflation [2].

Baldwin and Taglioni examined the dimension and the sign of the errors caused by the mistakes in the econometric studies previously presented [3]. The paper also analysis a number of problems related to data manipulation. To offer a reference point, the authors took as example the paper of Micco, Stein and Ordoñez, using a data set as close as possible to those regarding the analyzed years and countries.

The most recent paper of Jeffrey Frankel (2008) studies the causes of the discrepancies between estimations referring to euro's trade effects between member countries – approximately 15% result of own research and of other previous studies – and the estimates of the effects on other currency unions – up to 200% [13]. The author shows that the difference between estimations is not caused by one of the invoked reasons. Mainly, the difference is not caused by lags (or by the vision that it takes time for the monetary unions to have an effect on trade), by omitted variables, by reverse causality (trade can help the creation of a monetary union) or by the threshold effect (or the

vision that monetary unions can determine important increases of trade in countries with a certain dimension or with a certain income. In exchange, the paper shows that the difference between estimations can be determined by the sample size.

Rose (2008) considers the analysis of 26 studies regarding euro currency effect on trade [19]. The author observes that individual analysis of each study shows the fact that there is no consensus on the effects of EMU; a conservative estimation shows an increase with 8 percent, but there is also plausible a 23 effect. The hypothesis of no effect can easily be rejected.

In the same paper of Andrew Rose are synthesized the studies regarding the effects of trade on business cycle synchronization. There are analyzed 20 studies realized from 1998 to 2007. And in this case the results are heterogeneous; the idea that a change in trade volume has no impact on business cycle synchronization is incompatible with the results found. A more conservative estimation shows that every increase of 1% in the trade between two countries seems to lead to an increase of the correlation coefficient about 2 percent.

Berger and Nitsch (2008) formulated some critiques to Micco, Stein and Ordoñez (2003) study. Most important ones referred to: the euro effect is too large relative to EU membership effect, it appeared in 1998, a year before the launch of the single currency and the effect is heterogeneous among countries.

Baranga (2009) argues that trade gravity equations will always suffer from omitted variable bias and that including fix effects can never completely control for endogeneity problems, as at least one free dimension of error variation has to be left uncontrolled for in order to estimate the coefficients.

Despite these critiques, the prior empirical evidence finds that the euro trade effect exists, but is much smaller than previously thought and smaller than results obtained with non-euro data.

4. Conclusions

The endogeneity problem is relatively new and it makes necessary many empirical studies to prove its functionality. It remains an open question if the countries form a

monetary union because they have a high trade level or trade increase is due the fact they form a monetary union. At the same time, we can ask if countries can form monetary unions and wait to automatically appear the benefits of a greater integration.

The validity of Frankel and Rose arguments is controversial as a result of the fact that recent empirical studies confront with difficulties caused by the short period of time since the euro introduction and the differences in the methodologies used. Even though the triple effects of trade volume described by Rose have been rejected by many economists, monetary union positively influences trade openness of the countries that choose the participation to a monetary area.

Thus, after the analysis of many empirical studies regarding euro area, I can say that monetary integration in euro area had a direct consequence on trade growth. Even though there are no similar experiences and the time since euro introduction is relatively short for estimating the effects on trade, European monetary union is about to become an optimum monetary area.

Abstract

Connected to an environment characterized by dynamism, the organization faces both opportunities and difficulties. It must possess a high capacity to adapt to changes and quickly respond to the environmental signals.

The market or environmental instability may undermine the organizational behaviour and its objectives only if they have not existed or have been wrongly taken into account. One can appreciate that a clear horizon attaches importance and necessity to the incorporation of the company shares in a future vision, in an unitary and coherent policy-the marketing policy.

Key words: advertising, persuasion, communication, marketing strategies.

J.E.L. classification: M30, M31, M37

1. The Marketing Approach of the Advertising Representation

Viewed over time, the organization's marketing policy is characterized by a relative stability, a continuity of its defining features. The relatively sustainable marketing policy is mainly explained by the determining role of its strategic components, which relate to a specific time horizon. [3]

The particular features of the company's marketing policy and its promoting performances specifically reflect the ways the four elements of the marketing mix - product, price, distribution and promotion - are used in an appropriate combination. Their combination must ensure the adaptation of the company's opportunities to the external environmental conditions.

The future orientation of the company is increasingly required by the new conditions in which they operate, that is to say, by both the company's internal conditions (technical, organizational and others) and the conditions characterizing its external environment.

The future orientation does not imply only the increasing role of the foresights in making decisions; it is a global attitude, a behaviour that gives meaning to all business activities. This is the politics of the global marketing consisting of a mix of strategies and tactics.

The strategic orientation of economic activity is a feature of the marketing policy of the modern enterprise. The policy incorporates a set of marketing strategies that are appropriate to the conditions in which the organization operates. Being closely connected, the marketing strategy and policy are different concepts. They are in a whole-party relationship.

We live in an environment dense with influence attempts. A large number of the population makes a living simply by getting others to comply with their requests. Conservative estimates suggest that a person will receive up to 400 persuasive appeals *from marketers alone* in the course of a single day. In the situations in which a manager encourages productivity, a salesperson closes a sale, or a president tells us we need to spend more money on social programs, each of us is subjected to an uncountable number of influence attempts each day.

Bringing together the strategies and the related tactics, the marketing policy designates a company's particular "mode" of address and solving problems. The physiognomy of the marketing policy reflects not only the specific objectives of the

company but also the options regarding the ways to achieve its objectives.

In advertising, communicating a message is what the organisation wants people to know. People ask for information about its existence, offer or about the ways they can solve their problem. They are establishing a communication channel that is persuading people to listen.

In the composition of each of the four components of the mix there is a wide range of tactical elements; they represent the materialization of particular strategic guidelines established for each component. [6]

The marketing-mix designates the totality of all the variables that a company may use to influence the target market, namely how available resources are trained to get the desired effects. [3]

Each of the four basic components of the mix contains a considerable number of characteristic elements, called components of marketing (product, price, distribution, promotion) that can be combined in different ways.

Sometimes overlooked, often overloaded, it occupies an important place in promoting the theory and practice of the marketing. [1]

Promotional activity involves a complex communication with the market informing potential consumers about specific actions. Any business that produces or sells a product or service must communicate with the customers by sending them messages through various marketing communication techniques to create a favourable image of the company and its products.

2. Persuasion and Advertising

From our perspective, society is a massive group of people influencing, persuading, requesting, demanding, and otherwise manipulating each other to achieve their goals. We call it society because we persuade instead of physically coerce. Persuasion makes society work smoothly, while physical coercion grinds it to a halt. Successful persuasion makes physical coercion unnecessary, interpersonally and internationally. Thus, society benefits from persuasion. The individuals who know how to persuade benefit the most from society.

Persuasion is a communicative function that can be pursued in many different settings, ranging from face-to-face interaction to mass communication. Mass media persuasion takes three primary overt forms: commercial advertising (of consumer products and services), pro-social advertising, and political advertising. On each of these subjects, there is extensive empirical research and theorizing.

Studies of consumer advertising have examined such questions as the effectiveness of different advertising strategies, the role of endorsements in consumer advertising, effects of varying the frequency and timing of advertisements, the role of visual elements, and so on. Advertising is commonly one part of a larger marketing effort, involving decisions about pricing, product distribution, market segmentation, sales force management etc.

Pro-social communication campaigns (sometimes termed "social marketing" because such campaigns apply familiar marketing tools to pro-social ends) aim to forward environmental or charitable causes or to advance health-related ends such as encouraging people to exercise, quit smoking etc.

Research on health promotion communication has been informed by such theoretical approaches as the health belief model, the stages of change model of health behavior change, and the extended parallel process model.

Studies on political persuasion (especially, but not exclusively, in the context of election campaign advertising) have examined issues such as the effects of negative advertising and the role of televised political debates in elections.

The cognitive process of persuasion through communication is not new; we have leaned to associate cognitive thoughts and perceptions to a certain sets of emotions. The emotions arise as a result of our perception in marketing through the message and also through their level of awareness, acceptance and buyer stage.

If we change the perception, what will happen? Will that have an effect upon the persuasion? We deem that it will. The retailers created a change of perception with the sales. The retailers persuaded people to want to have. Surveys have shown that

people said that while they bought for others, their reason for going was, for them, too good to pass up. The retailers know this and create a message to them. Did they talk to the children's parents to get that doll or loopy loop Hot Wheels? It was certainly advertised in their sales circular and on the children shows but not so much on network TV. They changed the perception that we can buy for us. When we communicate do we persuade?

3. The Contribution of Advertising to the Overall Economic Welfare

The productivity of the economy should be seen both from the perspective of firms, and in terms of global economy. Obviously, companies need to advertise to prevent erosion of market share mark, even in the absence of total sales growth in a particular branch. However, many economists are interested in advertising from a macroeconomic perspective. That is, it can be said that advertising contributes to the overall success of the economic system, or only to the success of a particular company? Does advertising introduce effectively new products? Does it contribute to economic growth and creates new jobs?

Economists see advertising contribution to the economy divided into four categories. [7]

- Counterproductive. Advertising is counterproductive when prices increase or, in one way or another, creates dissatisfaction with products that are still useful.
- Unproductive. Unproductive advertising does not increase overall demand but do not bring any harm. Advertising aims to determine the brand change from existing customers included in this category.
- Less productive. Advertisements in this category result in an increase in overall demand but at a lower level than other techniques or an unreasonably high cost.
- Very productive. The most productive advertising produces the lowest welfare cost. The implication of this category is that both buyers and sellers have equal advantages.

It is difficult to use generalities when we consider the economic value of publicity. Advertisers' contribution to sales of products depends on a lot of circumstances unique to

each product. Utility market productivity of relatively new products such as personal computers, is much different from beer and tobacco industry market, which are characterized by uniform sales and brand changes between existing users. However, it is obvious that advertising brings a real contribution to profitability; otherwise companies would not use it.

4. The Social Role of Advertising

While the economic contribution of advertising is the major preoccupation of both companies and consumers in recent years, its social implications are increasingly considered. Almost everyone agrees, even the most fiercely critics, that advertising plays an important role in informing consumers about products, locations, prices and markets. These are the economic functions of the institution of advertising. On the other hand, social and cultural role of advertising is much less clear and is increasingly becoming a topic of discussion in some circles.

Many observers points out that advertising is both a mirror and a shaper of public opinion, social mores and standards. They maintain that the absolute value of exposure, advertising establishes a social agenda on what is expected, what is fashionable and what is good taste for a considerable number of people. This is manifested especially on young people, poorly educated and impressed. Many people deem that the way advertising embraces different segments of society - for example, the elderly, minorities, or young people – determines, to a certain extent, the way these people will be treated by others.

It is used in an active social role when advertising sustains the fight against the abuses to which children are subjected. [7]

5. The Excessive Visibility of Advertising

Advertising has been criticized. It is too much that becomes annoying. Most critics of this category are directed against television because print ads are easily ignored by turning the page. It is an established fact that both advertising by mail and telephone sales struggle against those who wish to apply

legal restrictions against the use of these promotional techniques.

With the rapid introduction of the new communication technologies, the fragmentation and the interactive nature of the future advertising vehicles will undoubtedly reduce much of this criticism. It is obvious that in the situations when interactive communication means will allow consumers to select programs, advertising and desired advertising info, advertising is unlikely to be considered troublesome.

6. The Undesirable Social Effects of Advertising

The accusations that advertising determines people to buy things they do not want or need degrade the moral principles and, in general, exploit the most impressionable segments of society. Most studies have shown that mass ads, especially insistent open communication, such as advertising, have difficulties in determining small changes in behavioural attitudes or intentions.

The idea that we see an ad and forced, against our will, to buy a product, seems to be absurd. Like any other mass communication, there are situations in which some readers or listeners behave in a manner that is totally contrary to the intention of the person that sent the message.

It is an interesting fact that the overwhelming majority of critics in this category is meant to protect other people, not the critics themselves. This means that most critics consider that, although a particular advertising item will not deceive them, they are obliged to help those less intelligent that can be deluded by an advertising artifice.

Criticizing advertising is not a new phenomenon. A brief review of the history of advertising and its critics demonstrates that both parties have considerably changed over the past 130 years. The public's opinion about advertising has changed over three periods:

- The age of exaggerated claims (1865-1900). During this period, most people have accepted advertising as a communication form such as "the buyer is able to take care of himself". In fact, any product presentation was allowed. Some

business presentations, especially for the so-called miracle drugs, were so unnatural that nobody could trust them.

- The age of the public's maturity (1900-1965). In the early twentieth century, laws such as The Genuine Food and Drugs Law and demonstrated that the public required an accurate description of public goods and services. Many responsible companies have feared for the existence of this economic activity because the misleading advertising was increasingly spreading at the end of the nineteenth century.
- The age of the social responsibility (1965-up to the present). In the past thirty years, the companies involved in advertising have understood that the simple truth was not enough to meet the consumer's demands. These companies are aware of the fact that they must meet a standard of social responsibility, in addition to the achieving a fair advertisement.

Although the main offenders in the field of televised debates have few supporters among the public, there is reluctance to the idea that advertising holders should "cooperate" with the producers as far as the content of the programs is concerned. In the same way that tobacco companies against the First Amendment condemns interpretation to prohibit advertisements cigarettes, many disagree with the direct involvement of companies in the content of programs, however accurate would be the reasons.

7. The Evolution of Brands in 2010-2011

David Haigh, CEO of Brand Finance asserts: "The rise of the technology brands has been expected for some time, although Nokia's fall shows that it is tough to stay at the forefront of such a dynamic industry. Over the last couple of years, we have found that, across many leading companies, senior management are increasingly using brand valuation dashboards to monitor the health of their brands throughout the year in order to make better informed strategic marketing decisions. This trend is likely to continue as the sheer size of these brand values becomes impossible to ignore". [8]

Table 1. The Top 10 Brands

Brand				Brand Value (USD \$ Millions)		Brand Rating		Market Cap (USD \$ Millions)	
2011	2010	Logo/Icon	Name	2011	2010	2011	2010	2011	2010
1	2		Google	44,294	34,158	AAA+	AAA+	143,014	157,970
2	5		Microsoft	42,805	33,403	AAA+	AAA+	143,724	199,969

Source:

http://brandirectory.com/global_500_2011.html

Although the top tier of the Brand Finance Global 500 contains many household names brands that have existed for decades – IBM, Bank of America, HSBC – the world’s increasing dependence on the Internet is reflected by Google’s position at no.1. Five of the top ten largest growers are technology-related companies, reinforcing the commercial importance of embracing technological innovation to give a seamless, value-enhancing brand experience for customers and consumers. ‘Don’t be evil’-Google’s dominance of the search engine sector means it tops the 2011 table. The company has repeatedly undertaken ventures that are comparatively un-commercial but have a positive impact on its brand rating (AAA+) which is the highest in the table. These actions include developing services help rescue efforts following the natural disasters in New Zealand and Japan and its growing not-for profit arm.

Apple’s success continues as it moves up twelve places, supported by innovative design, a very loyal consumer base and well-executed marketing activities. However, Coca Cola has dropped out of the top ten for the first time. This is underpinned by the consumer trend in developed markets to move towards healthier, non-carbonated drinks. Wal-Mart was one of the few brands to actually increase its brand value during the banking crisis due to its well-defined, value-

oriented proposition. Its value has dropped slightly but, due to its overall size, its marginal loss (12%) means it also becomes one of the largest losers for 2011. BP suffered a torrid time in 2010 although, according to a Brand Finance study in August 2010, the brand value had dropped as low as \$4.7bn. It has now rebounded to \$8.8bn but is facing further problems relating to its partnership with Rosneft. Nokia suffered the largest fall in brand value – \$9.9bn. The company has struggled in the smart phone market, a victim of Apple’s success, although the partnership with Microsoft may help to revive their fortunes. Facebook enters the Brand Finance Global 500 for the first time with a brand value of \$3.7bn. Although monetisation of the world’s largest social networking site remains contentious and its product diversification strategy remains relatively opaque, there is little doubt concerning the brand’s huge popularity, its effectiveness in entering new markets and stratospheric levels of consumer usage.

Advertising, as any other business, must operate in a complex environment of ethical, social and economic, in a business world increasingly complex, may not be offered easy answers to many questions raised as critics and supporters of advertising. Companies that advertise, their agencies and mass media continued to struggle with ethical issues of content, presentation and acceptability of multitude of product categories, statements and advertising practices. These problems have easy solutions and should be resolved on a case-by-case basis.

The key to successful advertising is the concept of putting the consumer at the forefront. Companies operating from the perspective of business management in a manner that favors the consumer will benefit themselves. Also, firms that carry advertising may not be blocked by any critic or critical opinion. Eventually, companies will have to listen to advice from the branch manager, who said that companies must take into account all criticism, but to follow his own conscience and their sentimental value.

Advertising industry leaders are increasingly worried about the attacks made on legal advertising and fair, the critics fail to

understand the social and economic value of unhindered communication.

As different phenomena happen in this space, the job is going to evolve. You constantly have to be challenging yourself, challenging your client and learning new things.

Strategic Measures to Decrease the Adverse Effects of Financial Crisis

Radu Riana Iren

"Dunărea de Jos" University of Galati,

Faculty of Economic Sciences

raduriana@yahoo.com

Abstract

Romania, as in all countries of the world, can not overcome the financial crisis without business growth, without finding opportunities for economic development and attracting investment into the country without. Successful managers find ways to overcome situations of uncertainty. The strategies adopted are based on a series of simplistic reasoning such as analogy, taking into account the ideas of experts, rigorous debate and experimentation. Business leaders today must deal with an avalanche of ambiguity, it must decide on the future of the company. In this paper, I propose to develop marketing strategy called "blue ocean" as an opportunity to transform challenges into opportunities of economic crisis.

Key words: crisis, blue ocean, strategic sail

J.E.L. classification: O16

1. Introduction

After a considerable number of failures and bankruptcies landslide, companies have begun to pay increasing attention to be justified, how they are managed in-house activities, and identify all possible threats and skilled construction plans to address them.

The first step is to differentiate between the problems, threats and actual crisis. Although we use the term crisis management, effective management of the crisis is, in general, that the crisis is not reached. Basically it's more a management problems, or efficient management of business. Amid economic crisis, more and more companies are facing with financial and budgetary deficit. In these circumstances it is necessary to find solutions to finance

economic activity, to be developed, implemented and effectively managed.

In this paper, which is structured 5 chapters, I propose such a strategy, called blue ocean strategy, strategy developed by foreign researchers, which try to apply the current situation in Romania.

2. Chaos and economic crises

Rigid structures based on functional specialization, behavior formalization of the hierarchy of authority and claim to have the mission to preserve and coordinate the rarest resource of all, the most valuable economic factor - the information. Currently, more and more economic values are incorporating information and knowledge. Therefore, increasing the productivity of information and knowledge is no. 1 challenge of the new economies. Solving this problem related, in essence, by increase use a factor of production, is the focus of information and knowledge where they are really necessary for making decisions and solving operational situations. As sources of information and knowledge are diverse, their concentration, "where should" implies the imperative, to ensure their free flow throughout the economic system [1].

In the current economic crisis, some sectors or markets have been hit particularly hard, are practically the outbreak of the crisis. Most corporations that make up these sectors have been facing a rapid quantitative expansion, being adjusted, especially through central planning, and vertically oriented with a strong vocation Directive. In such circumstances, any short circuit, in particular information and data, the hierarchical control of disseminates pathways, accumulation and distribution of errors throughout the system. It's about quality degradation feedback circuits and as a consequence, the potential losses of self-organization. Massive

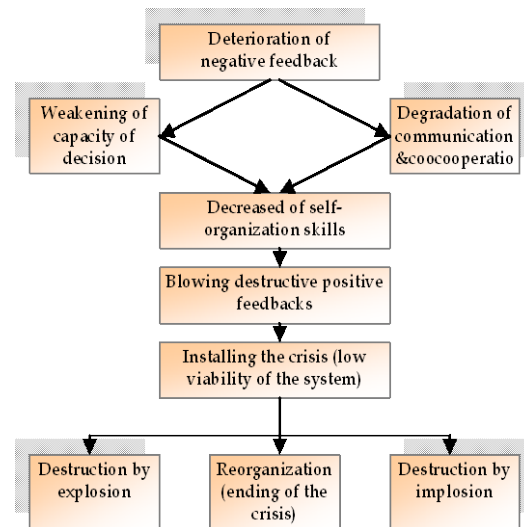

weakening of self-organization skills (based mainly on the horizontal relationships between the actors and autonomous decision-functional aspect) made impossible the resorption of these tensions dynamics of adjustment and "local" [2] adaptation.

The crisis is not simply a direct expression of these deficits: the systems are not able to be "The self" efficiently and simply, the "spoils". Any economic crisis is, above all, a crisis of adjustment, meaning that the mechanisms of information processing and knowledge, communication circuits, routines for cooperation and decision-making procedures do not work [3].

It begins with the deterioration of negative feedbacks that stabilize and control mission system. Malfunction negative feedbacks can happen under the pressure of both the external constraints, and those internal. The effect is essentially the same: the errors lead to error feedback control (management), and these, in turn, causes distortions in the functioning of the system. Impaired negative reverse connection circuit generates global and local decision-making capacity erosion and degradation intrasystemic communication and cooperation. Degeneration is to reduce the effect of these processes of self-organization skills. The harder is the recovering of the system from shock. More difficult problems are identified, mobilized resources, created internal and external connections necessary for effective action.

According to Vadim Dumitraşcu outlines the main elements of establishing a general model of crisis in the overall pattern of economic systems is the installation of the crisis.

Fig. no. 1. The overall pattern of the installation crisis

Source: Vadim Dumitraşcu, Smile of chaos. Management of hipercomplex systems Ed SEDCOM LIBRIS, Iasi, 2010, p. 127

The crisis begins when one or several variables of the economic system tends to shift to the border is the so-called "safe beaches", their behavior becomes unstable and abnormal, in other words is chaos. Installing the growing intensity abnormalities and, at some point becomes so great that manages to destabilize the entire economic system. Based on the model system - a company, we see a rapid increase in sales as possible (lead, after some time, adverse developments in other variables, resulting in those causing eventually a downward trajectory of the cash-flow and dangerous proliferation of various economic and financial risks [4].

The financial crisis that is currently going through was also triggered by a "local event" – bankruptcy of Lebman Brothers and ING banks - which has spread throughout the financial system violent world. A small economic crisis became the most highly consumed much of his energy and resources just to ensure simple survival.

The crisis is the negative aspect, destructive, destabilizing the chaos in economic systems [5].

In clarifying the mechanism of seizures in the economic systems, it holds an important place Volterra paradox: while the system no longer responds to stimuli that usually apply,

but instead displays the opposite behavior normal and expected [6].

The descriptive (qualitative) model of the evolving crisis could be an economic system. Let us assume a relatively simple economic system - company. Modeling this system based on two interrelated variables: the volume of sales (turnover) and cash flow (cash flow for the period), which evolves out of phase periodically.

Apparently, between turnover and cash flow, there is a positive correlation: higher sales increase cash flow and cash flow enhancement provides additional resources to expand operations and thus to further increase the annual business. However, this positive correlation only works in certain circumstances, and in others not.

Thus, too rapid a growth in turnover can cause, while a decrease in cash flow and, consequently, a reduction in future sales. Volterra is an illustration of the paradox. In this dynamic, can be detected following factors:

A too rapid sales growth, particularly if it becomes a normal development of the sector, followed by most operators will lead to market saturation and thus to a decline in sales and future cash flows.

Expansion of turnover may be driven mainly by lending to commercial customers to encourage purchase orders which mean a revenue deferral period and therefore a reduction in cash flow.

Multiply the number of clients will increase the percentage of bad payers' customers, with negative impact on earnings and cash flow.

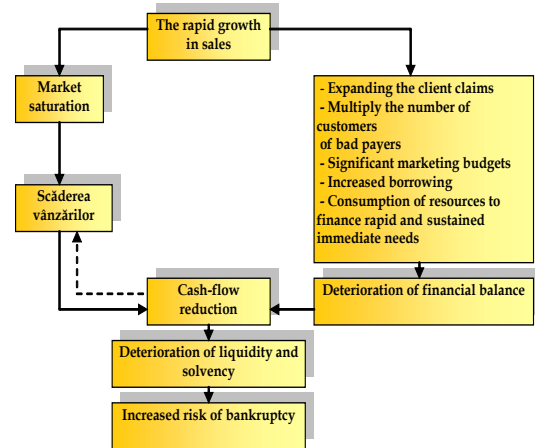

Turnover expansion means expanding the operating system (increasing the volume of current assets and assets), which means increasing financing needs both short and long term, with obvious negative effects on cash flow.

Expanding the market for sales growth may require significant allocation of marketing budgets, which will reduce cash flow.

Self-financing, regarded as a gross cash flow may not be sufficient to support the financing needs of increasing turnover, appealing to leveraged companies, a process that will reduce future cash flows from payments made in repayment of debt.

Entry mechanism in the crisis-business system is illustrated below.

Fig. no. 2. Installation mechanism crisis in the system – company level

We see a very rapid acceleration of growth in turnover can lead to suffocation financial-firm system. The two interdependent variables - turnover and cash flow – have not of the same period of development. Forcing one, in this case, the turnover will lead to the deterioration of values of other variable - cash-flow.

This development became possible because the firm left-attractor system stable, "friendly", which determines its behavior in the past, moving more in the area of influence of a chaotic attractor, "selfish". Stable attractor was represented by a prudent development policy management, balanced and rational, based primarily on grounds of sustainability of growth. Chaotic attractor is developing the new policy as soon as possible, which neglects important prudential restrictions, based on overly optimistic forecasts of future market developments. The company entered into a "whirlwind" of growth at any price, and while this growth has proven to be inconsistent in terms of money.

In this processuality, many errors are detected and feedback and destabilizing positive feedback. Imagine an entire sector or even more sectors are covered by such a "fever" of growth. In fact, this happened, at least if we consider the manifestations of the crisis in Romania. Let us remember the sudden drop in sales in the retail sector's durable goods storage platforms or packed

the car dealers or real estate collapse. These and other calculations have been based on unrealistic scenarios, but cyclically evolving markets, they can not grow indefinitely.

Each of the elements described above process creates specific risks, the cumulative action, fragile system, leading to a sharp weakening of financial balance [7] conditions:

- risk due to the fast-growing financial needs against available resources;
- increase the risk of not collecting due to bad payers customers;
- risk of non-recovery of expenditure invested in expanding the operational and marketing budgets;
- specific risk of borrowing;
- reducing the risk of liquidity and solvency.

Combined action of these risks, "hot" system, leading to a chronic financial balance and therefore increase the danger of bankruptcy risk.

3. Chaos between risks and opportunities

A critical feature directly related to the propensity of be a chaotic economic system, but also to stabilize their behavior, is the length (duration) of its normal operating cycle.

A typical operating cycle, specific micro-systems, the business cycle is the sequence of operations they carry out a firm from taking control of the customer and ending with receipt of invoice issued by the client.

Systems with short operating cycles are usually more sensitive, more frequent and can record large fluctuations in their functioning, but have at the same time, a stronger capacity to rebalance: they are "familiar" with the turmoil. Systems with long operating cycles are more stable, fluctuations in their operation being rarer and less spectacular if the shock enough to seriously disturb them succeed, it takes tremendous energy to stabilize them. The current economic crisis provides many examples: the most affected sector firms have been characterized by long business cycles (construction, metallurgy, shipbuilding, machinery and automobiles, chemicals, etc.), although the crisis first erupted in sectors

shorter business cycles (banks, financial services, retail, etc.).

4. Blue Ocean Strategy

W. Chan Kim Professor of Strategy and International Management at INSEAD, the firm Boston Consulting Group Bruce D. Henderson with Renee Mauborgne, Professor of Strategy and Management at INSEAD, Fontainebleau, France have developed the "Blue ocean strategy" [8] (2005) a famous book of marketing strategy that has been sold millions of copies sold and translated into 41 languages (Romanian and published by the Old Court, 2007).

The two teachers were studied over 20 years how to create novel market areas, so that competition becomes irrelevant. Their conclusion is based on a market universe composed of two sorts of oceans: some red, others blue. Red oceans represent all fields available today. This market area is known. Oceans blue means all areas which today still exists. This market area is unknown.

The central idea is this: it is pointless to continue fighting in "red oceans" with fierce attacks on the competitive market share and profits, but must seek or create "blue oceans", free from competition, which can grow rapidly and profitably. In red oceans of existing market you operate in and fight to be better than competitors by exploiting existing demand and choosing between differentiation and lowest cost. In blue oceans, creating a new market where competitors are irrelevant, develop and manage application and get the lowest cost and differentiation.

It criticized the theory that companies can create value for the client at a higher price (differentiation strategy) or to obtain a reasonable value at a lower cost (lowest cost strategy) and the proposed path of "value innovation" ("value innovation ") that create value and reduce costs at the same time.

In red oceans, within each business are defined and accepted, and the competitive rules of the game are known. By contrast blue oceans are defined as areas of virgin market with an application to be created with a high probability of profitable growth.

Although some blue oceans are created well away from existing areas within, most blue oceans emerge from the red oceans by expanding existing business boundaries, as

did the Circus of the Sun of Canada has developed a new circus, another audience, theater audiences closer than the public circus that Ringling Bros. and Barnum address & Bailey (Circus World Champion in the industry). In blue oceans, competition is irrelevant because the rules are not yet established.

"There will always be important to swim in red oceans, surpassing your competitors. Oceans will always look red and will always be a reality in the business world. "

A delicate situation is created when supply exceeds demand in more and more economic side, and goes fight for a share of a declining market, although necessary, however, will not be enough to maintain high performance.

Companies need to move beyond mere competition, and to possess the potential profits and take advantage of growth opportunities; they need to create blue oceans.

Unfortunately, blue oceans are unexplored because in the last thirty years the main concern in developing organizational strategy to focus on red oceans, based on the idea of competition.

Red ocean strategy, based on competition, "assumes that all branches of economic structural conditions are predetermined and that firms are forced to fight In a given framework. Scientists call this structural view or environmental determinism. In opposition to this vision is the specific value innovation blue ocean (see figure below).

Fig. no. 3. Red ocean strategy vs. blue ocean strategy

Red Ocean Strategy	Blue Ocean Strategy
Competing in an existing market area	Creating a market undisputed
Upgrading competition	Making competition in an irrelevant factor
Exploitation of existing application	Creating and attracting new applications
Compliance ratio value / cost	Abolishing the ratio value / cost
Adaptation of the whole system of activities of the company the option of differentiation or low cost strategy	Adaptation of the whole system of activities of the company's business objective of differentiation and low cost

5. Strategic vela

Strategic Vela is a diagnostic method and a framework for designing a compelling blue ocean strategy. Strategic Vela should answer two questions:

a) How come the red ocean of bloody competition for making your competitors irrelevant?

b) How to discover and take possession as a blue ocean, the undisputed market areas?

The following figure range on the abscissa the factors that are manifested in the provision of transport services in Romania inland today, and the ordinate shows the level offered to buyers for each key part.

Fig. no. 4. Rendering the Vela strategic cargo shipping services in Romania

Source: processing by W. Chan KIM, op. cit., p. 45.

As shown in the figure above, the industry sector provision of cargo shipping services, there are seven main factors influencing the market

- Price
- Duration of transit
- Transport capacity
- Charging time
- Time of discharge
- The subdivision of the ship
- Prestige carrier.

For a better interpretation of strategic sails, it must be supplemented by matrix eliminates, reduces, develops and creates that if SNCF NAVROM SA looks as follows:

Fig. no. 5. Matrix Elimination-Reduction-
Development-Create

<p>DELETE Additional maneuvers load times Disadvantageous mode of subdivision of cargo vessels</p>	<p>DEVELOPING Special transport different price than that of the general transport Involvement of port operators</p>
<p>DECREASES Offering unspecialized Working on the basis of commitment Bunkering operations</p>	<p>CREATE Competitive transit times Client access to temporary storage facilities at berth Combined Transport in collaboration with naval + road transporters</p>

Source: processing by W. Chan KIM, op. cit., p. 58.

6. Conclusions

Blue Ocean opportunities have always existed, and as have been explored, the universe expanded business. This expansion is the foundation of economic growth.

Blue ocean strategy challenges companies to leave the red ocean of competition by creating areas still undisputed, to determine competition becomes irrelevant. Thus, instead of dividing the existing demand, blue ocean strategy refers to an application already on the rise and the elimination of competition.

Through this work, we tried to challenge other companies to have the attitude that they adopt solutions for overcoming the financial crisis to the firm to achieve its objective by adopting a new mentality by putting into practice innovative ideas, those of creating "blue oceans".

Abstract

Blue ocean strategy challenges companies to emerge in the middle of the fierce competition that is by creating undisputed market areas which result in competition to become irrelevant. Only, instead of dividing the existing market demand, blue ocean strategy refers to a growing demand and to eliminate competition. Blue Ocean opportunities have always existed and have been explored as the universe expanded business. This expansion is the foundation of economic growth.

Key words: blue ocean strategy, competition

J.E.L. classification: M10

1. Introduction

W. CHAN KIM is Professor of Strategy and International Management at INSEAD, the firm Boston Consulting Group Bruce D. Henderson and RENE MAUBORGNE is Professor of Strategy and Management at INSEAD, Fontainebleau, France.

"Blue Ocean Strategy" (2005) is a famous book written marketing strategy by two teachers mentioned above, required reading in MBA courses, sold millions of copies and translated into 41 languages (Romanian and

published by The Old Court , 2007). The book is punctuated with many examples, case studies, and policy tools easy to use.

The two teachers were studied over 20 years how to create original areas, so that competition becomes irrelevant. Their conclusion is based on a market universe composed of two sorts of oceans: some red, others blue. Red oceans represent all fields available today. This is the area known market. Oceans blue means all areas which today still one exists. This market area is unknown. [1]

The central idea is this: it is pointless to continue fighting in "red oceans" with fierce attacks on the competitive market share and profits, but must seek or create "blue oceans", free from competition, which can grow rapidly and profitably. In red oceans of existing market you operate in and fight to be better than competitors by exploiting existing demand and choosing between differentiation and lowest cost. In blue oceans, creating a new market where competitors are irrelevant, develop and manage application and choose between differences and get the lowest cost.

It criticized the theory that companies can create value for the client at a higher price (differentiation strategy) or to obtain a reasonable value at a lower cost (lowest cost strategy) and the proposed path of "value innovation" ("value innovation ") that create value and reduce costs at the same time.

2. Blue Ocean Strategy

In red oceans, within each economic activity are defined and accepted, and the competitive rules of the game are known. By contrast blue oceans are defined as the virgin market with an application to be created with

a high probability of profitable growth. Although some blue oceans are created well away from existing areas: limits, most blue oceans emerge from the red oceans by expanding existing activities borders, as did Sun Circus in Canada has developed a new circus, another audience, theater audiences closer than the public circus that Ringling Bros. and Barnum address & Bailey (Circus World Champion in the industry). In blue oceans, competition is irrelevant because rules game is not yet established.

"It's always important to swim in red oceans, surpassing your competitors. Red Oceans are always looking for and will always be a reality in the business world " A delicate situation comes when supply exceeds demand more and more economic side, and go fight for a share in a falling market, although necessary, though not enough to maintain high performance [2].

Companies need to move beyond mere competition, and to take possession of the potential profits and take advantage of growth opportunities; they need to create blue oceans.

Unfortunately blue oceans are unexplored in the last thirty years because the main concern in organizational strategy to focus on red oceans, based on the idea of competition. [3]

Red ocean strategy, based on competition, "assumes that all branches of an economic structural conditions are predetermined and that companies are forced to go fight a given framework" [4]. Scientists call this structural view or environmental determinism. In opposition to this view, innovation is the specific value blue oceans (see Figure below).

Fig. no. 1 - Red Ocean Strategy versus Blue Ocean Strategy

Red Ocean Strategy
Competing in an existing market area
Upgrading competition
Exploitation of existing application
Compliance ratio value / cost
Adaptation of the whole system of activities of the company to strategic choice of differentiation or low cost

Blue Ocean Strategy
Creating a market undisputed
Making competition in an irrelevant factor
Creating and attracting new applications
Abolishing the ratio value / cost
Adaptation of the whole system of activities of the company's business objective of differentiation and low cost

3. Blue ocean strategy for Arabesque Company

To have brilliant performance, innovation is needed, creating something new or at least moving towards a new field, the blue ocean. First, there is a risk search or wrong choice of the field of commercial opportunity. This risk can be eliminated if it remains in the field of excellence and we try broadening of the six boundaries of competition: industry, strategic group, group purchasing, product or service use, functional-emotional orientation of industry, time.

If Arabesque, traditional areas of construction materials are markets for retail for merchants (Arabesque is now the largest wholesale market trader profile, with a turnover at the end of 2010 1.492.649.686 lei and commercial transactions occurred globally). New areas of opportunity for Arabesque e-commerce site are construction materials and the development of chain stores that final consumers. In light blue ocean strategy, the risk of wrong choice of domain boundaries is dissipated by increasing competition as follows:

- Expanding the Strategy Group - from a relatively small group (wholesale traders) in a large group (end users)
- Use of products and services - accessibility is extended to products and services of company
- Focus on emotional-functional branch of trade - the strategy is based on social impact, particularly among end users, and focus on a closer approximation of them, including the introduction of the 'door to door.

Secondly, there is a risk of entangling planning because no new action is unprecedented and can not be predicted correctly financial. This risk can be eliminated if you forget the numbers and focus on the visualization strategy. There are four steps:

1. Visual awakening when they first built the strategy chart (horizontal axis competitive factors, supply-side vertical axis for all competitors).

2. Visual exploration - analysis of the six boundaries of competition and innovative ways, the benefits of each alternative. How can I get a new value curve? The four types of action: reducing non-essential factors, the elimination of harmful or useless, increasing the positive impact and create new ones.

3. Visual presentation strategies - and are asked to draw feedback from enterprise customers, of competitors and non-customers.

4. Visual communication - is distributed before and after strategic profiles and supports only projects that lead to the target situation.

Thirdly, there is a risk of scale: the business will reach a size that ensures profitability. To counter this risk, should aim beyond existing demand. Those who are not customers can be classified into three categories: Category 1 - those waiting to become consumers, to test the product, Category 2 - those who refuse product, Category 3 - those who have never thought about the product. The rule is to attract those who are in greatest number. If Arabesque, the risk is covered scale, Category 1 - those waiting to become consumers holding the largest share among the three categories mentioned above.

Figure no. 1. The structure of potential market

Category I (70%) – Those who are waiting to become consumers

Category 2 (12%) – Those who refuse the product

Category 3 (18%) – Those who were never thinking to the product.

Fourthly, there is a risk business model. It is diminished if you follow the correct sequence by putting the four strategic questions:

1. Is there exceptional buyer utility?

2. Is the price affordable for the mass of buyers?

3. You can reach the target cost for a profit at the chosen price?

4. Can you solve the problems of adopting the product?

If Arabesque, the answers are all yes, so the idea is commercially viable.

Fifthly, there is an organizational risk can be overcome by providing organizational problems and treatment: cognitive problem (need not be understood), the issue of resources, motivation problem, political problem (there are opposing interests). The best way to overcome these problems is the "tipping point leadership, i.e. acting on key points with small resources to get the epidemic spread of a huge change. Rather than act on the masses, act on the extremes: Opponents and supporters make it visible and motivate them. Their actions will have disproportionate influence over the management of change.

Sixthly, we risk management. For it must be ensured that the strategy is being executed. Blue ocean strategy recommends a fair trial based on three E: engagement (commitment), Explanation (reasons), Expectation of clarity (clarity of expectations).

4. Drawing new boundaries of the market

The first principle of blue ocean Strategies refers to redrawing boundaries so necessary for the separation of market competition in creating blue oceans. The challenge is to successfully identify, from the multitude of existing opportunities, those opportunities own blue ocean and the commercially appropriate. KIM CHAN Renee MAUBORGNE Teachers have identified six basic ways to market boundaries withdrawn:

1. Prove alternative fields;

2. Prove the strategic groups within the two areas'

3. Three categories of buyers Prove

4. Search the complementary product offerings and services;
5. May prove functional-emotional existing customers;
6. Prove timing.

5. Conclusions

Good for the blue ocean strategies have three characteristics:

- Focus on objectives (for Arabesque, the objective is broadening the target group)
- Unique, divergence from the general trend in the industry (it is a new trend, to try to reduce supply chain and network address of the final consumer prices up by the importer, this phenomenon of globalization which is active for Arabesque, plays an important role by providing access to cheap supplies)
- An intention, a great slogan .

The major problem of blue oceans is their sustainability: how long it takes to make strategies to be imitated by competitors? Solutions can be sought among the barriers to imitation, and here is an interesting list that begins with the attitude of other companies to ridicule the new offer, the small size of the market that do not bear a second player, etc., but the real solution is still innovation to be ready again to look for a new blue ocean.

Blue ocean strategy becomes even more interesting in the context of the following observations:

- There are always great industries.
Attractiveness increases or decreases after a period of time.
- There is always excellent company.
Companies rise and fall in time.
- Creating a blue ocean is a catalyst for business and industry.
- Blue oceans are created by old players or new entrants.
- Oceans appear blue not only by technological innovations, but innovations in value.
- Creating blue oceans is correlated with strong and profitable growth.

Eco Tourism Contribution to Sustainable Development in Romania

Răbonțu Cecilia Irina

Babucea Ana Gabriela

"Constantin Brâncuși" University of Târgu Jiu

cecilia.rabontu@gmail.com

babucea@utgjiu.ro

Abstract

The theme of this paper is the relationship between tourism and environment, with particular reference to the ways of protecting tourist areas characterized by fragile ecosystems, such as parks and beaches.

This paper analyzes and tries to show that environmental protection is not only a legal obligation in relation to the hydro-geology of the territory, but could also become an important tool for strengthening a tourist area. Green Tourism is one of the recently entered words in our vocabulary, and which, although using it increasingly more often, sometimes we do not fully understand it. In fact this notion still seeks a more complete definition, closer to the area of activities it virtually covers. Most often the preferred formula is "tourism that does not harm nature."

Key words: green tourism, sustainable development, promoting eco tourism

J.E.L. classification: L83, Q01, Q57

1. Introduction

Tourist activities, particularly those related to mass tourism imply clear environmental and social costs. Among these the most important may be air pollution, water pollution, noise pollution, and excessive production of waste, water shortages during the peak season, ecosystem damage, fires, overcrowding and congestion.

Many resorts, particularly those most required by tourists can be identified in this scenario. Here, in fact, tourism seems to have reached a critical limit for some time, with reference to certain peaks of the season, a

limit that affects the actual quality of the capacity utilization.

Tourism is a big business. It is one of the largest industries in the world and in many regions is the single most common source of investment and workforce employment.

Although transportation, as a base service in the tourism product, does not have the same image of the 'chimney' as the manufacturing industry, it is not at all safe for the environment, generating significant levels of pollution and consuming considerable amounts of natural resources. Romania is an attractive and preferred tourist destination for at least the domestic tourists and, therefore, it faces significant challenges in its action to make green the tourism industry.

One of the biggest beneficiaries of a more sustainable tourism industry will be the industry itself in the sense that fewer people will want to visit a region where mass tourism has destroyed the rural areas and polluted the beaches.

The number of tourists in mostly all regions is growing. The tourism is one of the main causes of the high demand of transportation, especially for those ways with the most severe impact on the environment: private transport, and especially air transport.

2. The impact of tourism on the environment

Coastal areas, islands and mountain regions are the most vulnerable to tourism development. Already there has been an irreversible degradation of the environment in certain areas which are popular tourist destinations.

It is estimated that the impact of this sector will increase as a result of growing affluence of tourists and the lifestyle and demographic changes. Tourists' behavior remains still a

crucial factor for sustainable development of the sector.

In addition, regarding the types of architectural structures, the problem applies alongside the providing of tourist facilities such as parks, golf courses or water parks with high land consumption and a significant impact on natural resources (e.g. water) along with the connecting road infrastructure, often constructed with little or no respect for the precious and fragile habitats.

A second critical point was identified in the "induced development", namely the distortion of local economies that appear in order to meet the needs of tourists and can lead to severe environmental pressures. This is the case, for example, of the rapid development of agricultural activities in order to satisfy the food demands of tourists, which translates into an increased use of pesticides and water consumption.

A third set of issues is related to "the loss of habitat and biodiversity", which means the destruction or deterioration of the natural habitat that leads to extinction of plant and animal species.

There are also a number of problems related to the over-exploitation of the environment in periods of peak season. First, the lack of sewerage and wastewater treatment. Only 30% of sewage is treated before being discharged into the sea. This clearly has negative effects on the quality of bathing water. Even the tourist boats are a source of pollution. There are also various forms of "unsustainable exploitation of natural resources." In particular, excessive water use.

Finally, another form of pressure is to be found once the season starts in traffic congestion on linking roads, which is the most responsible for short-term traffic pollution.

3. Tools and policies to reduce the environmental impact of tourism

World Tourism Organization, Pacific Asia Travel Association, World Travel and Tourism Council (WTTC) are among the international and regional organizations to develop policies and guidelines on conservation and natural resource protection. It should be noted that the hospitality

industry has initiated an aggressive move to combat water losses and energy use, by reducing chemical use in laundries and increasing the use of recyclable materials like toilet paper, soap, etc..

The World Organization of Tourism publication "Tourism in 2010" shows that the twenty-first century faces two major problems:

1 a great responsibility and a profound respect for the destination host populations and their culture.

2 a great responsibility to those who traveling are reflecting on new ways of consumption, an increasing attention paid by tourists education.

Therefore, sustainable tourism reflects three important aspects:

- **Quality** - sustainable tourism provides a valuable experience for visitors, while improving quality of life of the host community and protecting the environment;

- **Continuity** - sustainable tourism ensures the continuity of natural resources on which it is based and the continuity of the host community's culture with satisfactory experiences for visitors

- **Balance** - sustainable tourism ensures a balance between the needs of the tourism industry, the environment and the local community supporters.

The goals of sustainable tourism can be found in the following areas: improving the host community's life quality, provisions on intra-and inter-generational equity, environmental quality protection by maintaining biological and ecological systems diversity, the insurance of cultural integrity and social cohesion of the community and the providing of a high quality experience for the visitors.

The integrated, balanced and long term development- the so-called type of "sustainable" or "supported" development - implies the existence of community policies that support 'green tourism' for the capitalization of rural areas. In this regard it is worth to mention the recent *Community Action Plan for Tourism* and the *Community Programme of policy and action on environmental and sustainable development*. Furthermore, structural funds were allocated (Structural Development Fund and Regional Fund) for development of rural tourism and training in this area. (12)

4. Measures to support green tourism in Romania

The system operators and managers of Romanian tourism and of the places with high fragility of the environment and beyond are increasingly aware of the risks posed by improper use of components in a travel environment.

Developing ecological tourism is considered incompatible with mass tourism in terms of environmental objectives. The main strategies are identified to reduce negative impacts of tourism (in environmental and social terms) are two: the concentration and dispersion of tourist flows (Collins, 1999).

Focus is aimed at reducing the impact of flows of tourism on an area, the method of achieving this goal is identified in the creation of attractive places where the resources are held accountable and the services are integrated, in places defined in the literature as honey pots.

The solution adopted in many sensitive areas of interest, primarily within national parks, seems not to be in accordance with sustainability criteria, which requires integration between development and conservation and not sacrifice some sites for the redemption of certain other sites.

A second option much closer to the principles of sustainability, is the spread in different areas and in various periods of time of the tourist flows. In this way, excess demand in tourism, in some places or at certain times, is approached by reducing the discomfort created by the seasonal peaks and concentrations in specific sites.

Once established that the number of visitors present in a given area exceeds its absorption capacity, the tools available to reduce this number are different, being possible the identification of direct and indirect methods of intervention.

Direct interventions are those aimed at reducing or regulating tourism activities by thorough supervision of the area and limiting access.

Indirect interventions, by contrast aim visitor behavior that can be influenced by actions on prices and supply opportunities, with large variations depending. In the latter

case, there is need to seek and find alternative travel segments that can contribute to the recovery of losses in the low season months, given the lower earnings from reduced tourist flows in peak periods.

The continuing increase in the amount of tourist flows involving the above issues combined with increased attention to environmental quality in the affected tourist areas and not only, necessitated a series of instruments with long-term action.

These tools can be classified into measures to restrict access, seasonal adjustment of tourist flows and increase of the number of units and tourism products labeled organic.

Considering data provided by the ministry empowered with the tourism problems, the cost of the losses caused by non conservation of biodiversity are at 7% of GDP.

In the absence of funding mechanisms of SOP or the Environment Fund, Romania's efforts in sustainable tourism development are near to the lower limit compared with those of developed EU countries. It is noteworthy that the state institutions should take concrete steps to save the biodiversity, a chapter where Romania continues to face delays from the rest of the European Union (EU). (11).

According to data from the Ministry of Environment and Forests (MMP) is found that Romania is within the limits imposed by the EU in terms of biodiversity with a cumulative margin of 17 percent. Official data posted on the website ONG Natura 2000 shows that on the territory of EU-27 countries, including Romania, have been identified nine biogeography regions. Among the EU member and candidate countries, Romania has the largest biogeographically diversity, distributed in five biogeography regions: mainland (most common), Alpine (in countries with mountainous areas), Pannonian (available in Hungary and neighboring countries), Black Sea (only in Romania and Bulgaria), steppe (only in Romania).

The list of proposals for Natura 2000 in Romania's case includes 108 SPAs (11.89 percent of the country) and SCI 273 (13.21 percent). The total area of proposed Natura 2000 sites represents 17.84 percent of the country.

Romania is in infringement proceedings before the European Court of Justice (ECJ) on protected areas for not respecting its commitment regarding the protected areas management. Romania, with its high biodiversity value, holds an important contribution to the Natura 2000 European Ecological Network.

Many of the existing proposals for Romania network sites list overlaps protected natural areas of national interest (national parks, natural parks and reserves). Environmental organizations affiliated to Natura 2000 NGO Coalition have made requests to the authorities to support the protected areas in Romania, one of which was to allocate a budget for them.

The next reporting that Romania needs to sustain before the officials in Brussels is set for the year 2013 and currently is being worked on finalizing a research on biodiversity done by the National Institute of Biology. Until then, in the first half of 2011, the EC will present a perspective on future sources of financing of Natura 2000.

After analysis of eco-touristy potential identified the following strategic objectives for the development of eco-tourism in the Romanian area:

- the development of regional organizational conditions specialized in promoting agro-tourism and alternative tourism;
- the official acknowledgement of areas with a rich touristy potential and the development of county cooperation with concrete responsibilities;
- the union of efforts in consolidating forms representing genre offers, in which both owners and local councils play a role;
- the conservation and protection of environment by taking all the measures concerning meadows, water courses, forest limits, etc.;
- the mending and modernizing of roads and equipment;
- the setting of population and the control of youth exodus;
- the development of information and instruction of rural population;
- the protection, conservation, and rehabilitation of natural patrimony in areas of scientific interest and of cultural and historical patrimony.

5. Romanian tourism eco-labeling

The purpose of introducing the eco-label is to promote products with reduced environmental impact, eco-labeling being a voluntary action. The Certification Program offers tourists the certainty that the tourism product they are buying is of good quality and contributes to nature conservation and sustainable development of communities in the area of the program.

The action of organic certification is possible for: accommodations (hostel with 25 rooms), travel programs offered by tour operators (at least one day, maximum 15 participants) and tourist destinations (areas that offer products, promotes and coordinates eco tourism services in a uniform manner).

Eco-Certified products are on the tourism products market since 2006. So far, 17 products have been certified (hostels and packages / tours) in the certification system "Eco-Romania".

They are available in various parts of the country: Retezat Apuseni National Park, Sibiu, Brasov, Saxon villages, Danube Delta.

The certification system "Eco-Romania" offers a wide variety of benefits both for those who carry out tourism activities, and tourists, and not least for the nature of Romania.

For the operators in eco tourism this is a simple method of recognition of the quality of their services and an opportunity to promote products/services as products "eco". For consumers of eco tourism, certification is a guarantee that the chosen products offer quality services and nature experiences in a way that does not impact the site, nature and culture.

Validity of a certificate in eco tourism is 3 years. The system is not binding; it is based on voluntary participation by its beneficiaries.

6. Conclusions

The concept of sustainable development is a goal of developing a bridge between watching a good chunk of time without spectacular results, even satisfactory, and a movement to save the nature and the environment.

Tourist activities, especially those of mass, require social and environmental costs such as air pollution, water and noise pollution, excessive waste production, water shortages, deteriorating ecosystems, crowding and congestion.

Strategies to reduce negative environmental and social impacts of tourism are: the concentration and dispersion of flow. Concentration strategy involves the creation of attractions (honey pots) in order to organize the necessary resources.

This solution is not fully in line with sustainability criteria because it does not realize the integration between development and conservation, assuming a "sacrifice" to save some places rather than others. The dispersion includes reducing the discomfort created by seasonal peaks and the degree of concentration in some sites.

The instruments available for policymakers to limit the environmental impact of tourism are: direct (monitoring, zoning, restricting access) and indirect (visitor behavior).

Access restriction tools require the imposition of a maximum number of visitors in a sensitive area, in accordance with regulations in force and also with a permanent control.

These tools are effective because they aimed at alleviating congestion of the end environmental interest, but there are side effects of tourists and residents.

The seasonal adjustment tool shows effective response to problems of congestion in peak periods and the possibility of extending the tourist product life cycle when it reaches the stage of maturity.

This requires the ability to deflect a part of traditional users in different periods of peak season (tools of taxation or promoting the advantages of the season), but also a reorganization of the tourism product concerning the interception of new application segments (sports tourism, environment, elderly people).

It also appears the possibility of refurbishing the premises for the adoption of voluntary instruments for accommodation (ISO, environmental, disciplinary) and eco-labels for tourist destinations.

Green Tourism knew a development in Europe and represents that form of tourism based on the use of rural heritage, with specific improvement of local resources.

Green Tourism can get one of the following meanings: all the tourism – environment relationships, environmental protection in tourism, direct contact in harmony with nature, a natural form of tourism, supportive to the nature, friendship between tourism and environment, the protection of the environmental resources by conscious tourist attraction, as to obtain economic benefits through nature for the nature; Generator of added value, given to the benefit of the Nature: well-being to human nature that creates wealth, compatibility between pleasure and joy experienced in the middle of the nature and the concern towards environmental resources, the knowledge of transforming leisure while spending as much relaxation time in nature.

Promoting green tourism in Romania can be achieved through actions focused on awareness for tourists and tourism operators on the role of that type of tourism in the sustainable development of an area, but also through the financial resources that will channel tour operators to find those products that will bring long term benefits in terms of financial and as well environmental considerate. European Eco-label identifies overall environmental performance of products and services based on life cycle analysis, but the trader is not obliged to apply to his goods or services.

Sibiu - The European Cultural Capital and Beyond

Richards Greg
Tilburg University, Holland
Greg@tram-research.com

Rotariu Ilie
"Lucian Blaga" University of Sibiu
ilie.rotariu@ulbsibiu.ro

Abstract

This study is a work in progress and presents the findings of field researches in Sibiu about cultural profile of tourist during and after the European Cultural Capital Program (ECOC). This paper focus on gender, age, education, occupational profile, usual holiday type used by coming tourists, visitor origin, previous visits to Sibiu, relation with the 2007 ECOC, sites visited and their score, spending. The overall conclusion is that cultural tourist profile in Sibiu has improved during the period for town tourism benefit.

Key words: cultural tourist profile, visitors' origin, education, scores

J.E.L. classification: L83, O17

1. Introduction

This study is a work in progress that presents some of the results of a ten year monitoring program on cultural and tourism development in the city of Sibiu.

This research is unique in that it is probably the first long-term study of the cultural and tourism development of a city in a former Socialist country in Central and Eastern Europe. The data in the current report build on and extend the analysis provided in the earlier report "The Impact of the 2007 European Cultural Capital in Sibiu: A long term perspective", published in 2010.

The backbone of the research program is provided by surveys and residents and visitors to Sibiu, conducted at regular intervals over the 10 years between 2001 and 2010. The most important findings of the research to date, largely based on the resident and visitor surveys, are presented below.

The surveys were conducted in sites around the city, with sampling over different days and times to try and achieve a representative sample of visitors.

2. Profile of visitors to Sibiu

In most cultural programmes, the most important segment of the audience is local residents. Not only are they numerically more important, but events such as the the ECOC are specifically designed to cater for the needs of citizens. In the case of Sibiu, however, tourism has also been particularly important, since Romania was being opened up the EU and because the ECOC in 2007 represented a unique opportunity to develop an image for Sibiu internationally.

The early results of the Sibiu surveys indicated that the proportion of men has increased and in 2009 and 2010 the proportions of men and woman were more or less equal. This to some extent reflects the shift in the types of events surveyed from fairly specialist to more general cultural events

Gender distribution of visitors 2001-2010

%	2007	2008	2009	2010
Male	49,3	60,5	51,6	49,3
Female	50,7	39,5	48,4	50,7

Foreign visitors were more likely than domestic tourists to be male, with almost 60% being men in 2009.

The age distribution of participants in cultural events in Sibiu also reflects general European patterns. The largest single age group is consistently 20-29, although visitors

over the age of 40 have also gained ground over the years. This may be an indication that Sibiu has developed a more varied cultural offer which is better able to cater for all age groups.

Age distribution of visitors 2007-2010

%	2007	2008	2009	2010
15 or younger	1	2	1	2
16 - 19	8	8	5	5
20 - 29	50	35	38	39
30 - 39	24	25	28	24
40 - 49	10	17	16	19
50 - 59	4	9	7	8
60 or over	3	4	5	7

The education level of participants in cultural events is consistently high, with almost three quarters of respondents having some form of higher education qualification in 2010. This is far higher than the level of higher education participation in Romania as a whole, and indicates that cultural events are attracting highly educated people to the city. This level is also higher than the average for Europe as a whole, as revealed by the ATLAS surveys of cultural tourists in different European countries

Highest education level (%)

	2007	2008	2009	2010
Primary school	0	10	2	2
Secondary school	4	8	8	7
Vocational education	11	20	16	17
Bachelor degree	16	40	58	53
Master or Doctoral degree	68	22	15	21

Over time the occupational profile of visitors also tends to be high, with a peak of 77% having a managerial or professional occupation during the ECOC in 2007.

Foreign visitors were even more likely to have managerial or professional backgrounds than Romanian visitors.

Many of those attracted to cultural events in Sibiu also have an occupation related to culture. This may be an indication that the successful events policy of the city has been able to raise the profile of Sibiu as a cultural centre, which in turn will tend to attract those in the cultural and creative occupations. Comparison with ATLAS data indicates that Sibiu tends to attract more visitors with a cultural occupation than the average European city (around 30%).

Occupational profile (%)

	2007	2008	2009	2010
Director or Manager	16	12	13	14
Professional (doctor, lawyer, teacher, etc)	33	26	25	23
Technical profession (technicians, nursing)	28	17	20	20
Clerical/ Administratio	9	20	18	15
Service and sales personnel	11	16	20	23
Manual and crafts worker	3	9	6	5

Perhaps not surprisingly, the type of holiday most frequently taken by respondents is sun and beach holidays. Mountain recreation is also popular, reflecting the location of Sibiu. More surprising is the fact that visitors indicating that they normally take cultural holidays has declined since 2007. This may reflect the fact that Sibiu has become a destination with wider tourist appeal for a general, rather than a specialist market.

Usual holiday type (%)

	2007	2008	2009	2010
Health/sports	2.9	13.9	5.1	4.8
Rural holiday	6.8	6.1	7.1	9.8
Touring holiday	15	18.2	13.7	14.4
Cultural holiday	16.5	19	11.1	12.7
City trip	16.9	9.9	15.2	17.0
Mountain recreation	21.3	13.5	18.1	20.5
Sun/ beach holiday	23.5	21.6	28.8	22.4

For foreign visitors, cultural holidays and touring holidays were particularly important.

In terms of area of residence, the largest single group of visitors is drawn from Sibiu itself, which accounted for almost half the respondents in 2009. Over the monitoring period, significant changes have taken place in the origin of visitors to cultural events. In general, the proportion of local participants has fallen while the number of visitors from elsewhere in Romania and abroad has increased. The growth in foreign visitors was most noticeable in the years up to 2007, when the ECOC recorded a record level of foreign visits, and has declined since then. This is at least partly in line with national trends, which have seen international tourism fall dramatically as a result of the economic crisis. However, the increasing importance of domestic cultural tourism is also a trend seen in other countries, for example as measured in the ATLAS surveys in Portugal

Visitor origin 2001-2010

	2007	2008	2009	2010
Sibiu	38	37	49	40
Elsewhere in Transylvania	12	23	23	16
Elsewhere in Romania	34	22	23	27
Abroad	16	18	5	17

Among the foreign tourists interviewed, the most important source countries were Germany, Italy and France, which together accounted for two thirds of foreign visitors recorded in 2010. Germany in particular has grown in importance as a source market for visitors, reflecting the cultural ties with Sibiu.

Top origin countries for visitors to Sibiu, 2010

	% of total foreign visitors
Germany	40.2
Italy	8.9
France	8.9
Spain	5.3
United Kingdom	3.6
Austria	2.4
Greece	2.4
United States	1.8
Belgium	1.2
Bulgaria	1.2
Canada	1.2

This picture in general reflects the pattern of visits to the ECOC in 2007 as well, except that the Netherlands was a much more important source market for the ECOC event (which may be related to specific events surveyed during the ECOC itself).

The proportion of visitors who have previously visited the city shows that it has steadily become an established destination within Romania. In 2001 less than half the visitors had been to the city before (even though most of the visitors came from Romania), whereas in 2009 and 2010 over three quarters had been to the city before. This shows that Sibiu has succeeded in generating a higher level of repeat visitation over the years, which is also related to improvements in the quality of the tourism product (see below)

Have you made a previous visit to Sibiu?

	2001	2008	2009	2010
Yes	49,6	68,1	80,0	76,0
No	50,4	31,9	20,0	24,0

Much of the repeat visitation since 2007 has been related to the ECOC. The proportion of visitors who had been to the city in 2007 grew from 50% in 2008 to over 70% in 2009 and 2010. There is clearly a high degree of overlap between repeat visitation to the city and having visited the ECOC in 2007.

Did you visit Sibiu in 2007?

%	2008	2009	2010
yes	50	74	72
no	50	26	28

There is also a strong relationship between those who visited the city in 2007 and those who participated in at least one ECOC event in that year. Again, it seems that the active ECOC participants have come back to Sibiu in relatively large numbers in 2009 and 2010, adding considerably to the long-term impact of the event

Did you visit ECOC events in 2007?

%	2008	2009	2010
yes	19,8	61,9	55,2
no	80,2	38,1	44,8

The proportion of first time visitors varies considerably according to the reason for travel. In particular, cultural events and attractions generate a relatively high level of first time visitation, whereas shopping or visiting friends and relatives are much more likely to be motivations for repeat visitors.

*Sites visited in and around Sibiu
(% of visitors)*

	2007	2008	2009	2010
Orthodox Cathedral	27	40	50	?
Bruckenthal Museum	27	71	61	57
Evangelic Church	25	60	46	39
The Lower Town	25	35	52	47
ASTRA Museum	20	58	58	54
The fortification	19	25	38	33
Fortified Churches around Sibiu	12	24	24	19
Street animation		50	42	43
None of these	36	4	7	4

Multiple responses allowed. One of the key questions about a major cultural event such as the ECOC is the effect it has on the consumption of cultural attractions by visitors. People who came to the ECOC in 2007 primarily to participate in an event in the ECOC programme obviously have a positive impact on the economy and the cultural life of the city. But if they also get involved in the wider cultural life of the city and visit other attractions, this may help to spread the impact of the event and to persuade visitors to stay longer in the city.

The evidence from 2007 suggests that almost two thirds of respondents also made visits to other cultural sites in and around Sibiu.

Since 2007, it is clear that visitors to the city have been visiting an even wider range of attractions. In particular, visits to the Lower Town and the Fortifications have increased, reflecting the investment in these areas.

The investments that Sibiu has made in culture and tourism certainly seems to have paid off, because visitors now rate the quality of their visit to the city much more highly than in 2001. The ECOC in 2007 did not in itself produce an increase in the quality of experience, which may point to a more critical cultural audience being attracted by that event. However, it seems that one legacy of the event is a markedly increased visit quality.

Even though foreign visitors scored Sibiu lower on average than Romanian visitors, it is clear that they also tend to give relatively high scores, with over three quarters scoring a 9 or 10.

Quality score distributions for foreign visitors 2010(scale 1-10)

An important aspect of the ECOC is the economic impact that it can have on the host city. The bulk of the economic impact of the ECOC usually comes from visitor spending, because visitors inject new money into the local economy. In 2007 we estimated that the total economic impact directly attributable to staying visitors to the ECOC was €19.35 million. It is difficult to compare this figure directly with other years, because the ECOC as a direct visit motivation is no longer there.

However, the figures on average visitor spending show that spend levels have increased since 2007. The average visitor to Sibiu now spends almost twice as much as the average visitor before 2007. Again, this underlines the structural change in the nature of the tourist market.

Average total visitor spend 2001-2010

3. Conclusions

The ultimate measure of success for any project is the extent to which it has been able to meet the aims set for it. If we look back to the original aims for Sibiu 2007, we can see that the most important aspirations were:

- Raising the profile and changing the image of the city
- Attracting more tourists
- Enhancing local pride

- Growing the local audience for culture.

The changing of cultural tourist profile seems that the city was able to meet all of these aims. The visitor surveys indicated that those visiting Sibiu cover a large diversity. In spite of it, many of them are repeat visitors that show the power of attraction of the town.

The large number of tourists coming to the city was also significant, as this had boosted the cosmopolitan nature of the city and the feeling that the city had something to show the rest of the world.

An overall conclusion, based on close observation of the city and nearly 10 years of survey research is that the ECOC in 2007 was the first time that Sibiu had developed a clear (cultural) tourism product

Going Concern after the Global Downturn

Ristea Luminița

luminita.ristea@crgnexia.ro

atrandafir04@yahoo.com

Abstract

One of the fundamental accounting concepts which underlie the annual financial statements of companies all around the world is “the going concern principle”. This paper presents “going concern” as a major risk assigned to the business environment starting with 2008 during the economic downturn from the auditor’s perspective. Positive features can be viewed at the horizon after the crisis including the major improvements in auditor’s approach when dealing with “going concern assumption” in connection with going concern risk. These aspects are going to be detailed in this study including the additional assurance and tests of the auditors in dealing with management assertions in respect of going concern versus professional judgment and skepticism.

Key words: going concern principle, global downturn, reasonable evidence, Clarity Project, material uncertainties, adequate disclosures,

J.E.L. classification: M42

1. Introduction

Going concern is a very complex concept that includes: going concern principle, going concern assumption, going concern value, going concern risk. The core of this concept refers to a viable business that should continue to use the resources and to operate in the foreseeable future for at least 12 consecutive months and has no risk of being wound up (gone concern).

Going concern principle is one of the accounting principles that is included in generally accepted principles (GAAP) and

refers to a company's ability to continue functioning as a business entity

Under the going concern assumption, an entity is ordinarily viewed as continuing in business for the foreseeable future with neither the intention nor the necessity of liquidation, ceasing trading or seeking protection from creditors pursuant to laws or regulations. Accordingly, assets and liabilities are recorded on the basis that the entity will be able to realize its assets and discharge its liabilities in the normal course of business.

Going concern value is viewed as “the value of a company as an ongoing entity”(www.investopedia.com) and this value differs from the liquidation value of a company, being the value of intangibles associated with the running of the business, such as goodwill and intellectual property(www.investorwords.com).

Going concern risk is associated with the auditor and the impact in auditing activity will be further developed and presented.

2. Going concern risk and auditor’s approach

Going concern risk is the risk associated with the auditor during overall audit process: preliminary assessments of going-concern, planning, performance of the audit and completion and reporting. An auditor shall consider whether the use of the going concern assumption is appropriate, and whether there are material uncertainties about the entity's ability to continue to operate as a going concern that need to be disclosed in the financial statements.

The biggest challenge for an auditor is to issue a going concern opinion because this “prophecy” may have dramatically implication in company’s existence and in

the auditor's professional activity, being subject to severe moral and ethical dilemma. A going-concern opinion has always fundamental impact in shareholders' and creditors' confidence in the audited company.

The concept of going concern has been in the profession's headlines during the last 3 years due to the economic climate and it is a very sensitive area where auditors and the audit clients alike encounter major difficulty in applying the concept.

The possible questions asked by the auditor may be:

1. Have I obtained sufficient and reasonable evidences in connection with understanding of the client's business that makes me comfortable (taking into consideration the Code of Ethic and Conduct requirements) to document that there is a threat of going-concern in the next 12, even if this going-concern opinion will escalating the financial distress of my client?

2. Have I obtained sufficient and reasonable evidence in connection with understanding of the client's business, even if it is the risk that interested parties wouldn't be informed in time of the possible failure of the company, that makes me comfortable (taking into consideration the Code of Ethic and Conduct requirements) to document that issuing a going-concern opinion might promote timelier rescue activity?

In both cases the auditor has a huge risk if his going-concern opinion fails:

- Question no.1- the auditor has not obtained sufficient evidences and the going concern was wrongly interpreted by the auditor and this situation can bring important prejudice to a viable company that should have been resources to continue its activity. In this case the auditor may be subject to lawsuit initiated by the client

- Question no.2- the auditor has obtained sufficient evidences but due to the intention to "protect" the audit from further financial implication in respect of inability to obtain new capital and an increase in the cost of existing capital company, he failed to inform the shareholders and creditors about the critical problems of the audited company. In this case the probabilities to be sue and held responsible is very high (WorldCom, Enron, Parmalat).

New research in this domain have been carried out in 2011 by Antony Young and Yi Wang Multi-risk level examination of going concern modifications) and focuses on all Australian listed companies within the volatility industry of building. This research examined all auditors' going concern modifications along with all indications of going concern problems identified by directors. The findings have demonstrated the above assertions about the major problems of auditors when dealing with going-concern opinion. The auditors have been more affected (the level of under reporting of going concern risk by auditors was of 75 per cent) that directors (the incidence of underreporting was of 57 per cent).

3. Changes in the evolution of going-concern concept since 2001 subject to research and studies

Several studies and research tried to present, using an empirical approach the close relationship between an auditor and his failure to express an appropriate going-concern opinion and also the various factor that influences this matter.

In 2005 Marshall A. Geiger, K. Raghunandan, and Dasaratha V. Rama examined the changes in the likelihood of bankrupt firms having received a prior going-concern modified audit opinion. (Recent Changes in the Association between Bankruptcies and Prior Audit Opinions) and noticed that beginning with 2002 the auditors became more conservative in their opinion. The main reasons of auditors presented in the research can be presented as follows:

- enhance their reputation as a high-quality auditor
- reduce the auditor's litigation risk
- give the heightened level of investor and public scrutiny of the profession
- to be proactive in an attempt to reduce the extent of government intervention and legislation imposed on the profession.

Another study of Geiger and Rama, dated 2006 (Audit Firm Size and Going-Concern Reporting Accuracy) indicates that over an extended 11-year period, auditors issue modified opinions to only about half of their client's who file for bankruptcy in the succeeding year. This finding was a warning

signal obtained using empirical consideration for the concerns expressed by legislators in respect of the lack of prior warning by audit firms.

Another new study has been prepared in 2007 by Tae G. Ryu and Chul-Young Roh (the auditor's going-concern opinion decision) and research the implication of materiality threshold level among BIG five and non-Big five and the study finds that Big five had higher materiality threshold and were less likely to issue a going-concern opinion to their clients with financial problems than non-Big five firms.

A new research based on an empirically study published in 2008 by Ilias G. Basioudis, Evangelos Papakonstantinou and Marshall A. GeigeR (Audit Fees, Non-Audit Fees and Auditor Going-Concern Reporting Decisions in the United Kingdom) reveal that the magnitude of both audit fees and non-audit fees are significantly associated with the issuance of a going-concern modified audit opinion, i.e. financially stressed companies with high audit fees are *more* likely to receive a going-concern modified audit opinion, whereas companies with high non-audit fees are *less* likely to receive a going-concern modified audit opinion.

In 2009, Brad Tuttle and Scott D. Vandervelde initialize a research (DOES THE GOING CONCERN AUDIT OPINION HAVE A STABILIZING EFFECT ON THE OVERALL STOCK MARKET?) that revealed that an important role for going concern opinions is to stabilize the broader market and not just to inform investors about companies with the going concern.

New investigation in going concern reporting decision has been researched by Linda A. Meyers, Jaime J.Schmidt and Michael S. Wilkins in May 2010 (An Investigation of Recent Changes in Going Concern Reporting Decisions Among Big N and Non-Big N Auditors). The findings revealed that those non-Big N auditors became more conservative while Big N auditors became more accurate.

Taking into consideration the above presented research and studies we can summarize that after the big scandals generated by major failures of auditor in issuing an appropriate going-concern opinion, the accounting profession has come under an increased scrutiny over recent ten

years and especially in the period of the economic downturn.

There were several motivations such as: the continuing concern of the accounting profession, legislators, third parties and the public regarding early warnings from auditors about pending client failures in the form of modified audit opinions, and the need to assess the impact of the new economic condition that severe influence the auditing environment and auditors' opinion.

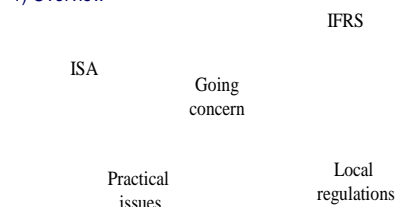

4. Effective changes in auditor's reporting as a result of economic crisis

As an immediate effect of the global downturn and the implication in the financial reporting and auditor's opinion, the IAASB, serving the public interest has completed so called "Clarity project" at the end of 2008 and has determined that all of its clarified standards are to be effective for audits of financial statements for periods beginning on or after December 15, 2009.

Going concern in the global downturn

1) Overview

The main target of this project was to set high quality international auditing and assurance standards that are understandable, clear and capable of consistent application, thereby serving to enhance the quality and uniformity of practice worldwide. (IAASB basis of the conclusion).

According with IAASB, the Clarity Project comprises 36 International Standards on Auditing (ISAs) and International Standard on Quality Control (ISQC) 1, including:

- One new standard, addressing communication of deficiencies in internal control;

- 16 standards containing new and revised requirements (these have been referred to as "revised and redrafted ISAs"); and

- 20 standards that have been redrafted to apply the new conventions and reflect matters of general clarity only (these have been referred to as "redrafted ISAs and redrafted ISQC 1").

ISA 570 "G5INTERNATIONAL STANDARD ON AUDITING 570, GOING CONCERN" has been an important part of this project that includes the main matters and concluded that, since the going concern assumption is a fundamental principle in the preparation of financial statements, it is appropriate for the auditor, in fulfilling the auditor's overall objective of obtaining reasonable assurance about whether the financial statements as a whole are free from material misstatement, to obtain sufficient appropriate audit evidence about whether management's use of the assumption is appropriate.

The IAASB also agreed that the form of the objectives appropriately reflects the two substantive elements of extant ISA 570 (Redrafted):

- appropriateness of management's use of the going concern assumption
- whether there are material uncertainties about the entity's ability to continue as a going concern that need disclosing
- whether there are adequate disclosures about going concern

Highlights possible warning signs including may include the following aspects in respect of:

financial issues		operating issues	other issues
adverse key ratios	borrowing facilities not agreed	loss of key management and staff	non compliance with statutory requirements
negative operating cash flows pre or post	indications of withdrawal of financial	loss of a major customer, license, supplier etc	pending legal claims which could not be settled

year end	support		
borrowings approaching maturity	substantial operating losses pre or post year end	fundamental market technology changes	changes in legislation with adverse effects
over reliance on short term borrowing	cessation of dividend payments	dependence on a few products where market depressed	issues with a wide range of outcomes
major restructuring of debts	inability to pay creditors when due	shortage of important supplies	
net liability position	non compliance with loan terms	obsolescence of key products	
unable to raise finance for essential investment	reduction in trade credit terms		
substantial sales of fixed assets not replaced	reduction in cash on delivery

5. What comes with the going concern after the crisis?

In a healthy economic environment going-concern has not been too much of a problem for the auditors, but a combination of the downward economic climate and the more risk-averse attitude of the banks to lending will mean that much more in depth consideration will need to be given to this issue. Auditors have a more important and sensitive role in assessing if a company is

subject of going-concern or not. Market conditions merely increase the risk of a potential material uncertainty materialising and increases the level of uncertainty in assessing future outcomes. Therefore the "blanket policy of emphasis of matter" is not the answer for the auditors anymore.

Forming an opinion on financial statement will be a higher degree responsibility work that an auditor can carry out and according with the new ISA 570 redrafted it is essentially to adopt the decision tree approach and to range of opinions for going concern issues in accordance with a very comprehensive evaluation of any of the possible warning signs presented above that may affect your opinion. Even if there is adequate disclosure the auditor need to use his professional judgement and to use emphasis of matter even to draw readers attention to this. That is not to say that we will see modified audit reports, i.e. 'emphasis of matter' paragraphs, everywhere we look, although inevitably the number will increase.

This new challenge for the auditor also raises the necessity to take into consideration the following aspects:

Ethical considerations – provision of non-audit services relating to refinancing and restructuring e.g. advising on valuations, advising on forecasts or projections, advising on restructuring programmes, advising on funding/financing

Quality control review – consider involving independent partner review at planning stage and completions stage for non-standard audit reports

Limitation of auditor liability – consider limiting or capping audit liability for high GC risk clients if allowable under local law and commercially viable. Also review specific conditions in professional indemnity insurance (e.g. prior warning of qualifications)

Legal advice – Take legal advice or specific specialist advice on certain issues [ISA 570] e.g. on complex intellectual property rights and revenue streams thereon

Bank confirmations – the absence of confirmation bank facilities does not itself cast doubt upon going concern or require

going concern to be referred to in the audit report – it must be looked at individually on the evidence to hand.

The main objective of auditor in the general level of uncertainty in financial reporting and economic environment is to encourage disclosure concerning judgments and assumptions made by the economic entity. If this issue is properly done than the risk of material misstatement and wrong audit opinion is getting lower.

stanciu_ionela09@yahoo.com

Abstract

The objective of this scientific approach is to present a valid and reasoned opinion on the contribution of a modern method of cost calculation, ABC method (Activity Based Costing), in improvement of managerial accounting, to conduct a comparative study of traditional methods of calculation and to highlight the benefits of adopting and implementing modern methods of calculation. ABC method is a methodological approach of "refining" the system costs, that places in the centre of cost matter the concept of activity.

Key words : activity-based costing method, cost driver, activity, limits, benefits.

J.E.L. classification: M40, M41.

1. Introduction

The *purpose and the objectives* of this research is to study, present and adapt the modern methods of calculation of production costs in the energy sector. To achieve this goal, I suggest the implementation of ABC method (Activity Based Costing), aiming, through others: examining specific principles governing this method revealing the causes that led to choosing the method of activity-based costing; transverse reorganization of entities where the method is to be implemented, taking into account the organizational and technological aspects of production in energy system, development of system accounts used for consumption and cost reflection on activities, specific to the entities in the energy sector; preparation of specific documents that match the needs of

evidence, analysis, control and highlighting the links between them; contribution of activity-based costing method to develop methodological and informational support to the energy sector entities.

2. Research methodology

Approaching the theme of research focused on investigating the ABC method of calculation, by presenting the general reference framework of the theme in literature. *Descriptive research*, used as research strategy, involves a preliminary study of collecting information in a complex research project, being used for the knowledge of systems and social processes.

The research type used is, on one hand *quantitative research*, based on the principles of *positivism*, and of *neo-positivism* and, on the other hand, *fundamental research*, aimed at deepening the theory.

The main research scientific methods used in my approach were the *analysis* and *synthesis*. The selection of these research methods directly depended on the nature of the studied phenomena, but also on the theory from which this study is claimed. I also made use of the *empirical method*, which is the simple observation of the facts without making assumptions, and of *experimentalism*, that both complements and opposes empiricism. Experience aims to control the assumptions, being a mental and rational operation, that brings certainty.

3. The theoretical significance and the practical value of this study

The theoretical significance of this study consists of the following issues: finding the need to address the complexities of the training costs of the production in energy sector, developing principles and methodology of accounting for production costs, highlighting the advantages of activity-based costing method and demonstrating the need for its application, The argumentation of the need of using the information provided by the ABC method to determine the steering indicators focused on the dashboard for managerial decision making.

The practical value of the work is to develop concrete suggestions referring to improving the method of accounting specific to activity-based costing method, namely: transverse organization of entities in the energy sector, on activities and processes; adaptation and use in the General Chart of Accounts on the production and cost accounting according to the specific method of calculation of activity-based costing; use the allocation process based on cost inducers or cost drivers of expenditure of activities and processes on objects of calculation, creating the dashboards based on the steering indicators specific to ABC method, setting the sequencing of the successful implementation of the ABC method and ensuring the continued operation - post-implementation of this in the energy sector entities, designing and using forms of supporting and calculation documents specific to ABC method.

Further on, I will try to outline a *qualitative analysis* of the state of my research up to this moment, I will describe the evolution of this methods of calculation and its framing in all modern methods of calculation used by managerial accounting.

4. The objective and the benefits of the ABC method

ABC management method is one of the new strategic initiatives in business, being considered by specialists an innovation in cost management. From conception to maturity, depending on the area of users' origin, ABC method (Activity Based

Costing) received different meanings. While some economic professionals have called it "technical" and other "process" or "system", researchers have given it the title of "method". Regardless of how it was made, the ABC method circumscribes to a continuous effort to improve the activity of an entity, with a dual role, of analysis and evaluation, being applied in accordance with accounting principles to interpret data on costs and provide a serious source of information which management decisions to be based on. *The origin of the method of calculating the cost on activities is found in U.S. literature, in "The Hidden Factory" developed by Jeffrey G. Miller and Thomas E. Vollman, in which it is subjected to critical analysis the sectors generating the indirect costs* [1]. The two authors have examined with great accuracy the places of production of indirect costs, reaching the conclusion that it is very important to assign a decisive role in controlling costs to the development of more detailed model of the causes of these costs. They have not insisted on creating a new system for determining the costs, but on the detail of producing indirect costs and on the measures to be taken at clarifying the causes which have contributed to record negative deviations of indirect costs

Some authors stated in the literature that the first attempt for the achievement of such a computer system and cost analysis dates back to 1987, belonging to Kaplan, Cooper and Jhonson. According to Robert Kaplan's statement "*costing calculation and the inspection procedure of the costs at that time did not show the production costs distorted and the nonfinancial crucial data was necessary for business efficiency and effectiveness in a new competitive environment.*" Coming out in 1989 in Germany, the paper "*Calculating process costs*" by Horvath and Mayer, was the starting point in the development of the so-called process costs calculation. The two concepts introduced by the authors, "Activity-based costing" and "Process-based costing" are used in the international literature as synonyms.

Since the beginning of the activity-based costing method (ABC), other methods have also appeared, such as: ABM or ABB. *Activity Based Management* (ABM) was defined as a systematic method of planning,

control and improvement of labour and indirect costs, being focused on the concept of "activities consume costs". If the traditional systems of costs were focused on the idea of 'labourer', ABM system is centred on the idea of "labour", the building core of ABM being activity-based accounting. *ABC method is motivated by the belief that, traditional accounting information is not useful to managers, who are interested in assessing the effectiveness of decision resources allocated in their businesses* [2]. *Activity Based Budgeting (ABB)* is the reverse side of activity-based accounting, being a systematic method of planning and budgeting the resources of an entity. In essence, this method defines cost per target and plans work tasks for each activity to determine the number of employees and expenditure budgets. Activity-based accounting is *a system that allows to follow the development of an enterprise in an "interactive" manner. This can be taken in any field, regardless of company profile. The new approach is (in different ways and with different names) to steer the company through its management activities and processes* [3].

Empirical research conducted on the effectiveness of the ABC method have shown its benefits by supporting the continuous improvement process of the activity, by developing methods to determine actual costs, by increasing financial performance. Although the ABC method has found rapid acceptance, however, there were a variety of views on the effectiveness of the method. In time, by simulating the transition to this method of calculation, in literature were identified a number of factors which influence the effectiveness of using this method, especially financial factors. Study results have confirmed the benefits of the ABC method, when it is used in parallel with other strategic approaches and when implemented in complex business entities in which costs are relatively important.

The ABC calculating system was born because of criticism to traditional cost calculation model, which uses the allocation process, according to which allocation bases were not the real model in which the products consume resources [4]. The practical application of the ABC method was performed for the first time in the "General

Electrics" company in the 60s in the U.S. The main causes which led to the need to apply this method of calculation were: shortfall in deepening of modern costing systems, deficiencies in traditional costing systems, diversity of information requests for company management and producing changes in the strategic position of companies on the market.

ABC method hypothesis is that careful analysis of the activities should lead to identification of relationships that more products maintain, little by little. The ABC method rejects cascade allegations and seeks to keep relations between costs and the causes that have triggered them. For this reason it considers that each entity producing directly productive activities also ensures peripheral activities. Thus, for each product a list of directly consuming activities is being drawn and also of those the activities generate. Basically, we are dealing with two types of activities: *on one hand, activities that can be attached to products, also called **primary or main activities** (are those used outside the entity, either by a product or by another entity; they express the main mission of the entity but they do not necessarily have a direct relationship with the products that can be support activities); on the other hand, we consider the activities that the entity carries out in a conjunct manner to the main activities, as their support. They are called **secondary activities** and they are not related to products* [5]. ABC Method (Activity-Based Costing) was perceived as an alternative to traditional accounting systems, having the specific of organizing the production process as a set of activities. Managers were asked to consider the resources consumed by these different activities, and only then to allocate costs to products. Practically, the ABC method is based on the entity's cut into transverse. It has been noticed as a measurement process of operations costs using: analysis of costs elements, determining activity-based performances, measuring production and operational costs.

In fact, the ABC method (Activity-Based Costing) is *an instrumental extension of the ABM method (Activity-Based Management). Activity-based management method is an excellent way to improve the quality of managerial decisions, relying heavily on*

information provided by the ABC method [6]. The objective of the ABC method is the allocation of effective action activities determining costs. "People can not manage costs, they can only manage activities that determine the costs". The basic principle of the ABC method can be described as follows: activities consuming products / services that consume resources. Products and services may be assimilated to processes. The relationship between the three concepts can be expressed by two equations: "consumption" and "necessary". The processes consume sub-processes or activities which in turn consume resources. Resources are needed both for carrying out activities and for implementation of processes, whereas processes consist of activities. If each stage of the relationship is.

5. Conclusions

The applicability of the ABC method highlights two categories of benefits: advantages of applying the ABC method over other methods of calculation and competitive advantages of entities which apply the method to those that do not apply it. The first category of benefits includes issues such as: identifying the causes of low performance and negative performance, eliminating the damage limits of the cost of products from dividing the entity in productive and unproductive components, identifying the real players in the overall performance of the entity, delimitating and identifying the most profitable and the most unprofitable components of entity's business, ensuring the achievement of performance management through cost drivers. The essence of applying the ABC method is not cost calculation but determining its origin on the background of functional relations. Establishing customer profitability through the two components of the cost (product cost and customer cost), accountability of staff, adaptation to continuous changes on market are some competitive advantages of entities applying the ABC method.

ABC approach is demanding in terms of mapping activities and the "anticipation" of support in relation to the products. Getting a real advantage, entities with multiple sources of deviation may be ignored in their economic consequences. Every success has its limits and the applicability of the ABC method has encountered a number of critical factors that contribute to the failure of its implementation. These include: heavy volume of work in collecting the information it requires, the accuracy of provided data, absence of a computer program, confusion in the preparation of other records in addition to those from financial accounting.

Error Detection in ESL Teaching

Rogoveanu Raluca

"Ovidius" University of Constanta

ralu_ionita@yahoo.com

Abstract

This study investigates the role of error correction in the larger paradigm of ESL teaching and learning. It conceptualizes error as an inevitable variable in the process of learning and as a frequently occurring element in written and oral discourses of ESL learners. It also identifies specific strategies in which error can be detected and corrected and makes reference to various theoretical trends and their approach to error correction, as well as to the relation between language instructor, students' motivation, classroom activities and assessment strategies.

Key words: communicative competence, error correction, error detection, coorrective tools, corrective strategies.

J.E.L. classification: Z 00

Over the last decades, the concept of error detection and correction in communicative language teaching has acquired buzzword fashionability in ESL teaching. It features proudly and prominently in innumerable books on methodology, articles and conference papers and scholars compete in exploring the various dimensions, uses and mutations of the concept. This study documents some personal insights related to ESL teaching and addresses issues regarding the fluid conceptions and misconceptions surrounding error correction in the larger paradigm of our beliefs, knowledge and current teaching practice. My reflections are based on empirical observations and discussions with high school and university teachers in the area of ESL teaching. This article deals with the pedagogical applications for error analysis and error correction and is addressed to foreign language teachers, second language teachers, be they in the pre-university or university

levels. The article does not specifically discuss why learners of L2 make errors, as they can stem from a variety of causes: interference between L1 and L2, the second language has inherently confusing aspects, the teacher and/or the course materials unintentionally lends itself to erroneous interpretations, learners foster their own second-language errors or errors are merely careless, unrepeatabe mistakes. The study focuses on the relation teacher-student when the variable of error is introduced. It also aims to address practical questions related to error reception and correction. A review of the literature on error correction identifies answers to five fundamental questions:

1. Should errors be corrected?
2. When should errors be corrected?
3. Which errors should be corrected?
4. What methods should there be used in correcting errors?
5. Who should correct students' errors?

Traditional perspectives on error detection and correction recommend instructional procedures conducive to quick error detection and the use of such strategies that would prompt students into producing error-free utterances. Although they admit the inevitable character of errors, the theoreticians recommend adequate instruction so as to prevent mistakes from occurring. "The principal method of avoiding error in language learning is to observe and practice the right model a sufficient number of times; the principal way of overcoming it is to shorten the time lapse between the incorrect response and the presentation once more of the correct model" (Brooks 58)

Such an approach also favours the idea that the chance for learners to make mistakes is minimized by practicing each grammatical pattern through stimulus-response drills until it becomes a habit. A number of studies have investigated the effectiveness of explicit error

correction in grammar instruction. Tomasello and Herron found that learners taught with a technique that induces them to make errors and then immediately corrects them did better in oral and written tests than those taught with traditional grammar instruction.

Structural linguists introduced the concept of contrastive analysis as a more effective technique to deal with students' errors when practising L2. They start from the assumption that interference from L1 caused errors to occur the target language. Contrastive rhetoric describes patterns of rhetorical preferences in other cultures, patterns which may explain and justify some inappropriate choices in terms of rhetorical strategies. Therefore, without adequate knowledge of cultural preferences, teachers are likely to see differences as weaknesses and quantify them as errors. In order to avoid generalizations, one needs to consider at least two issues: 1. not all members of a particular ethnic group may manifest all the problems or cultural preferences associated with a group (see for instance the preference of Arab students for digression in composition) and 2. not all problems arising can be attributed to transfer of L1 patterns. Once aware of this phenomenon of language interference or transfer, the teacher can identify adequate strategies and exercises meant to alleviate a certain problem

The focus on communicative competences started in the 1980s determined a change in the approach to error detection and correction and fostered new directions in determining learning goals, instructional materials and methodological strategies. In the light of the new principles, students are no longer expected to produce flawless structures in a foreign language, but to communicate in L2 about things that are relevant for their interests, even if this implies the tolerance of some minor mistakes. The educators tend to adopt a more lenient and tolerant attitude toward language mistakes and regard them as omnipresent facts of life in the learning process. Moreover, they consider that an adequate and systematic error analysis can provide useful insights into the process of language acquisition and indicate the rate of students' progress in a foreign language. "Errors provide feedback, they tell the teacher something about the effectiveness of his teaching materials and his teaching

techniques, and show him what parts of the syllabus he has been following have been inadequately learned or taught and need further attention. They enable him to decide whether he must devote more time to the item he has been working on. This is the day-to-day value of errors. But in terms of broader planning and with a new group of learners they provide the information for designing a remedial syllabus or a program of reteaching". (Corder 265)

The process of error detection as such can be a tricky problem, because the teacher finds it hard to discriminate between deficiencies arising from the student's low level of language proficiency or faults determined by weak writing skills. A two-paragraph essay written by an ESL student can indicate either of the following things: 1 linguistic difficulty : the student's lack of language proficiency prevents him/her from fully expressing the otherwise abundant ideas which he might be able to express in his native tongue. 2. the rhetorical difficulty : the student is unable to identify a number of consistent ideas and structure them into a fully developed essay

Harris and Silva (534) identify the following types of errors most likely to occur in the speech and written productions of high intermediate and advanced ESL students:

- Verbs Inflectional morphology (agreement with nouns in person, number, etc.)
- Verbal forms (participials, infinitives, gerunds)
- Verb complementation (the types of clauses or constructions that must follow a particular verb)
- Nouns Inflection (especially in terms of singular/plural and count/mass distinctions) Derivation (deriving nouns from other parts of speech)
- Articles (related to problems in classifying nouns)
- Misuse of article
- Prepositions (primarily a result of limited lexical resources) Knowing which one goes with a particular noun, verb, adjective, or adverb
- ESL students with lower levels of proficiency may also exhibit more problems with basic sentence, clause and phrase structure

In the act of learning, students may encounter different linguistic environments which construct various interactional contexts in which the teacher's feedback (in the form of error correction) may be immediate or delayed. The act of improving the knowledge and skills of a foreign language necessarily entails the transition from many errors - few errors - fewer errors and in the happiest cases - no error at all. When students are unable to detect their own errors, they need the assistance of a person whose language skills are superior to their own. If done correctly, without intimidating or making students lose confidence, error correction can prove an invaluable teaching instrument that helps student set higher and higher goals in language acquisition. This is particularly true in the case of adult learners, who express their specific desire of having their mistakes corrected and being also explained the rationale behind the rule. Many of them usually report that such mistakes which have been "topicalized" during the lesson through commentary generate meaningful knowledge in the future.

Before analyzing and correcting an error, this needs to be localized, in the sense that the teacher needs to know what was actually said or done, by whom, what was meant and what was intended to be conveyed.

Many foreign language educators have moved away from the obsessive concern with error avoidance and feel that discriminating between minor and serious errors can definitely improve the students' confidence and motivation. Research on students' evaluation strategies and their attitude to them seems to suggest that students prefer "not to be marked down for each minor speaking and writing error because this practice destroys their confidence and forces them to expend so much effort on details that they lose the overall ability to use language" (Walker 103). To put it differently, students would rather be praised and encouraged for their overall ability of communicating a message successfully, despite the existence of some errors, rather than be held responsible for each imperfection of their discourse. Other educators employ different corrective tools, depending on the type of exercise practiced. If in grammar exercise drills error correction can be seen as an acceptable mechanism, in communicative

activities, students feel the need to receive a type of feedback meant to instill success.

Foreign language practitioners consider that mistakes should be prioritized according to the intelligibility criterion. Once an error prevents one from comprehending the message, then such an error should receive top priority in correction. If errors do not interfere with the overall meaning of a message, they may not be promptly or systematically corrected. We described such a distinction in minor vs serious error. Burt and Kiparsky propose the distinction between global errors (as communicative errors that causes a native or proficient speaker to misunderstand or consider a message incomprehensible) and local errors (linguistic errors that makes a form or structure awkward, without preventing a native or proficient speaker from understanding the message). Global errors are usually associated with poor lexical knowledge and seriously misspelled lexical items. Local errors are occasioned by misuse or omissions of prepositions, misspelled words, lack of concord and agreement. The writers suggest that the teachers should aim at eliminating global errors first and only later should he/she attempt to remedy local errors as well. Teachers should be particularly aware of errors that tend to become permanent rather than transitional entities in someone's discourse. Such "fossilized" errors should also be corrected based on their degree of incomprehensibility (Waldman) The general rule to apply in this case is: the more an error detracts from the overall meaning of a discourse, the sooner should the teacher consider remedying it.

When correcting students' errors, teachers should avoid using correction strategies that intimidate and embarrass students and deter them from producing meaningful responses in the future. Once the tone of the correction has been decided upon, the teacher needs to figure out the answer to another pressing question: Should students be provided with the correct form or structure immediately after their error has been detected or should they be encouraged to identify the right variant on their own? This last variant is supported by Waldman who considers that a discovery approach helps students make inferences and formulate concepts about the

target language, thus "rooting" the information in their long-term memories.

There are specificities concerning errors in oral and written productions respectively. An error spotted in conversation is easier to correct due to proximity in time (error moment-correction moment). However, the teacher should refrain from interrupting the flow of conversation. A better approach is to note down/remember all the mistakes and then start the correcting process as soon as possible. In the case of written productions, error correction can be a more time consuming process, as the teacher is faced with a variety of mistakes, from spelling to word omissions to morphological, syntactic and pragmatic errors. Wingfield lists five techniques for correcting written errors (p. 311):

1. the teacher gives sufficient clues to enable self-correction to be made;
2. the teacher corrects the script;
3. the teacher deals with errors through marginal comments and footnotes;
4. the teacher explains orally to individual students;
5. the teacher uses the error as an illustration for a class explanation.

Most teachers feel that the responsibility of correcting students' mistakes lies entirely with them. As the teacher is expected to act like an invaluable source of information, it is only natural that he/she should react to errors as they feel most appropriate. Not only is the teacher expected to correct the error, but he also needs to provide data, examples, information in order to ensure the adequate understanding of the concept and prevent the mistake from reoccurring. Teachers who work with ESL students have the tendency to "tell" things, to provide cultural, rhetorical and/or linguistic information in order to help their students cope successfully with classroom tasks and home assignments. Indeed, tutors will not be able to elicit knowledge from ESL students if the students do not have that knowledge. However, an increasing number of teachers suggest alternative strategies. Such an approach favors the involvement of other students in the correction of oral and written errors. Peer correction makes students more aware of their own errors and more willing to learn

from each other's contribution to classroom discussions and activities. In cases of written texts, the teacher can assist students in their identifying and remedying their own errors. Moreover, students can be helped to develop effective personalized strategies for revising and editing a text. Such goals can be successfully achieved especially if the teacher works with a small number of students.

In the case of ESL students it is worth remembering that teachers should not have unrealistic expectations and ask from their students a native-like level of correctness. Language instructors teaching students who are not majoring in letters, and who are likely to use English as an instrument rather than as an end in itself should adopt a positive attitude towards error and accept it as inevitable in the discourse of their students, thus focusing on substance rather than on style.

Teaching and Learning Culture

Rogoveanu Raluca

"Ovidius" University of Constanta

ralu_ionita@yahoo.com

Abstract

This study is premised on the idea that culture teaching and learning should become a staple in foreign language curricula, as it fosters cultural awareness and understanding and has a positive impact upon linguistic competence at the same time. The article illustrates specific strategies by means of which culture-related topics can be integrated into classroom content. Specific references will be made to the elements that prevent language instructors from using culture-related activities extensively in classroom setting. Throughout the study, culture learning will be defined as is a dynamic, developmental, and ongoing process which engages the learner not only cognitively, behaviorally but also affectively. More specifically, culture acquisition is the process of acquiring the culture-specific and culture-general knowledge, skills, and attitudes required for effective communication and interaction with individuals from other cultures.

Key words: ESL, culture teaching, culture learning, communicative competence, cultural context, intercultural competence.

J.E.L. classification: Z00

Teachers associate language teaching and learning with the development of essential linguistic skills such as reading, writing, listening and speaking. Due to the effort of theoreticians and practitioners of education starting with the 1980s, people involved in language teaching have begun to understand the inextricable relation between culture and language and realize the fact that without the study of culture, teaching L2 is inaccurate and incomplete. Indeed, acquiring a new language means a lot more than the manipulation of syntax, morphology and semantics. What is more, without appropriate

exposure to cultural elements, most language learners find it hard to develop acceptable linguistic skills.

This study aims to investigate whether cultural knowledge can become a valuable source of understanding in the classroom and identify the relation between increased cultural awareness and linguistic competence. Does the incorporation of culture into the foreign language curriculum have a positive impact upon L2 communicative competence? If so, what techniques can language instructors implement in real and concrete teaching and learning situation with a view to fostering cultural insight into the target civilization? What assessment techniques are more likely to test the students' cultural competence? The study also considers the relationships among culture, classroom setting, curricular materials, instructional methods, assessment strategies and students' motivation in order to introduce students to a type of learning which shapes and restructures their perspective on the world and their cultural identity.

This study documents some personal insights related to ESL teaching and addresses issues regarding the fluid conceptions and misconceptions surrounding culture teaching in the larger paradigm of our beliefs, knowledge and current teaching practice. My reflections are based on empirical observations and discussions with high school and university teachers in the area of ESL teaching and stirred by a paradoxical personal finding: ESL educators are adamant about the necessity to integrate culture-related task in their curriculum, yet in concrete learning situations they seem to favour and discreetly promote grammar and vocabulary learning at the expense of interactive, negotiated and interpreting activities that capitalize on culture teaching. While reading and interpreting the personal ideas mentioned below, caution must be taken so as to avoid a narrow and

deterministic interpretation of personal insights which may favor stereotyping and overlook individual variations and evolutions. The topic of **teaching and learning culture** has recently raised considerable interest to language educators and much has been written about the role of culture in foreign language teaching instruction. This is hardly surprising as culture learning is not only the domain of language teachers. On the contrary, the field is highly interdisciplinary in nature, as contributions to this area have come from psychology, linguistics, anthropology, education and intercultural communication.

McKay considers that culture influences language teaching in two ways: linguistic and pedagogical. Linguistically, it has an impact upon the semantic, pragmatic, and discourse levels of the language. Pedagogically, it determines the choice of the language materials because cultural content of the language materials and the cultural basis of the teaching methodology should be carefully considered prior to deciding upon the language materials. For example, while some textbooks provide examples from the target culture, some others use source culture materials.

Culture has been defined mostly in terms of "facts" about the target culture. The emphasis has been on culture-specific knowledge and that knowledge has been primarily about surface-level, visible culture (food, clothing) rather than deep culture (values, beliefs). There has been little written on culture defined in more culture-general, intercultural competence terms. This is precisely the reason for which modern teaching should set new culture learning goals and outcomes. The learning goals should shift from the memorization of cultural facts (including sociolinguistic conventions for language use) to higher order learning outcomes including: the acquisition of "interactional competence" (a term suggested by Allen and Moore at the 1996 culture conference in Minneapolis) and learning how to learn about culture. According to Paige (1997), such learning would include:

- 1) learning about the self as a cultural being,
- 2) learning about culture and its impact on human communication, behavior, and identity,
- 3) culture-general learning (learning about universal, cross-cultural phenomena such as cultural adjustment, including its language)
- 4) culture-specific learning (learning about a particular culture)
- 5) learning how to learn(becoming an effective language and culture learner)

We feel the last point is particularly worthy of our attention and the lines to follow will elaborate on it. To become effective culture learners, students must develop a variety of learning strategies ranging from observation and reflection to active experimentation, all under Kolb's term of 'experiential learning' style.

Culture Learning in the Classroom

Practitioners and theoretician of education and language acquisition alike confirm that the benefits of studying abroad to the fostering of culture-sensitive individuals. The real challenge lies in imagining the classroom setting as a locus conducive to culture learning, creating a context for culture learning in the classroom means finding ways to approximate the target culture in the classroom.

According to Krashen , the formal classroom as a venue for culture learning does not lead to language or culture acquisition, only to the learning of rules. Others argue that there may be little difference between learning in the classroom versus learning in a natural setting because introductory or intermediate level students cannot communicate sufficiently well to take advantage of the naturalistic environment (Van Lier). Most researchers though, fall somewhere in between and consider that there are both disadvantages and advantages to language and culture learning in the classroom.

There are several trends of theoretical criticisms of the classroom as an environment for culture learning. Damen (1987), for example, argues that classroom-based learning is cognitive and deductive in nature and relies far too much on rule-ordered teaching. Consequently, students simply memorize the material without reflecting or

integrating it into a larger cultural knowledge base. Ellis (1992) considers that the classroom discourse is rigidly controlled by the teacher, who determines who speaks, how long they speak, and when they start and stop. Accordingly, this type of setting offers students little opportunity to become culture sensitive individuals. By contrast, naturalistic settings do not emphasize the clear articulation of rules, as the meaning is more important than the form, and error correction rarely occurs. However, other authors have theorized that the classroom as an artificial community can provide unexpected benefits for language and culture learning (Kramsch). The above mentioned researchers state that the classroom is a protective environment where students can feel free to make mistakes without enduring consequences. This protective setting enables students to experiment with the language, thus encouraging them to make sense of the language and culture on their own. Ellis argues that both environments can be satisfactory as long as the tasks that are utilized in the classroom are adequate for the purpose of the learning. As Freed notes, the stress should not fall on the external environment, but the internal one created by factors such as the type of instruction, the level of the class, and the individual differences associated with the teacher and the students. This does not mean that the external context is unimportant, as each type brings different potentials and problems, but it is the interaction between external and internal context that determines the type of learning to occur (Freed). Breen suggests that classrooms should be described as living cultures which are interactive, differentiated, collective, normative, asymmetrical, inherently conservative and jointly constructed.

One of the most effective strategies to integrate cultural content into classroom activities is to use examples, data, and information from a variety of cultures (or from the target culture) in order to illustrate key concepts, principles, generalizations, and theories in their subject area or discipline (Banks, 1993, p. 5). This general goal can be operationalized when considering the following concrete activities:

1. integrate culture-related activities into lesson plans
2. use cultural contexts for language – practice activities (grammar, speaking, listening and reading)
3. exploit meaningfully textbook illustrations and photos
4. encourage students to investigate the connotative meaning of new words when teaching vocabulary
5. devise adequate tests to assess cultural understanding
6. propose activities that contrast between national culture and target culture

However, teacher of ESL are reluctant at integrating a rich cultural content in their activity. Most of them justify their choices on the little amount of time they have at their disposal, time which needs to be devoted to language based activities. Another reason which teachers are less willing to admit is the insufficient knowledge of cultural issues. Lack of adequate resource materials can be another deterrent that keeps teachers away from culture teaching. Prior to the 1990s, most of the textbooks published in Romania did not consider the multiple realities which make up culture, as the underlying belief was that a homogeneous and relatively static national culture is easier to structure, present and teach. Now the availability of informational sources and means expose students and teachers to a large variety of cultural materials and the target culture reaches students via “authentic cultural materials”. In classroom settings, the textbook is used extensively, function as instructional guide, and determines themes and sequence of material. Furthermore, textbook influences most of the internalized knowledge the students had of English culture. As textbooks still remain the central tool to language educators and the main source of culture learning course book writers need to revise the material included in such materials, and the course instructors should also consider ways to supplement it with relevant materials. There is a large and growing body of theoretical writing concerned with the use of authentic materials, and concrete ways of including these materials into the curriculum have been devised. Nonetheless, there is little actual

research which has investigated the effects of authentic materials on linguistic or cultural competency.

Another thing that prevents language instructors from including judicious culture-related material in their classroom activities is the anticipation of students' negative attitudes. Indeed, although many students are likely to enjoy the opportunity of being exposed to cultural information, there are some other who consider any other material which is not strictly focused on language as a distraction from language instruction as such. Motivation can be broadly defined as the factor which drives the student to study a language in the first place and to stop studying to it. However, the identification of motivational factors may be different from student to student, depending on their age and proficiency level. What determines one to start studying a language may be different from what compels him to continue the language study, or to begin a third or fourth language where it is not required. Momber and Myers both found that students need high motivation to continue, but that motivation as a trait is highly unstable. The same student, for instance, may resort to different motivations in various stages of his academic existence. Attitudes can be generally defined as the positive or negative feelings that students have toward the language, the language teacher, the language class, the culture(s) of people who speak that language, and the study of the language. A student might be highly motivated to study a language and culture for instrumental reasons, which would not necessarily entail the development of positive attitudes towards the target culture.

Last but not least, teachers find it difficult to measure cross-cultural awareness and change in attitudes. Unlike linguistic or vocabulary issues which can be easily evaluated and the teacher's feed-back can be given almost instantly, it is hard to quantify the extent to which students internalized cultural norms and precepts. Kordes, Meyer, Byram and Morgan have identified the enormous challenges that go hand in hand with the assessment of culture learning and this perhaps the reason for which many educators abandoned the idea altogether. Byram notes that in England, the Minister for Education left out criteria associated with

cultural understanding because it was felt that only "practical communication" could be listed as a criterion for learning. Other researchers have concluded that culture learning can only be evaluated through informal means and only "by the learners themselves" (Damen). Whether we accept it or not, for many teachers, culture teaching and learning is a relatively new and unfamiliar topic. The problem lies in the lack of concrete examples of how to teach intercultural competence and in teachers' misconception that they need to be culture experts. However, the target at which teachers should aim is to become guides and partners in a process of culture learning and discovery with their students, rather than culture expert upon whom their students exclusively rely for cultural knowledge.

Abstract

The aim of the present paper is to underline the international financial crisis implications on the monetary policy transmission mechanism at the European level. Our study illustrates the main features of the pass-through process in the light of recent financial tensions and the general impact of Eurosystem's non-standard measures on the functioning of monetary transmission channels. Our results outline that pass-through process remained operational during the crisis and that unconventional measures ensured a proper functioning of transmission of monetary policy impulses to real economy. The extent to which this mechanism has been irreversibly damaged by the credit crunch is premature to determine and thus it would be misleading to draw definitive conclusions, especially when some non-standard measures are still in place and financial tensions persist.

Key words: monetary transmission mechanism, pass-through process, financial distress, unconventional measures

J.E.L. classification: D53, E52, E58, G01

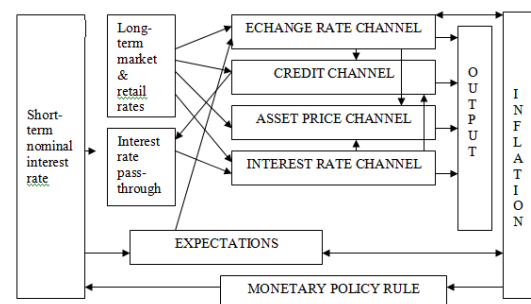

1. Introduction

Based on various channels, monetary policy transmission mechanism allows monetary policy decisions to influence the behavior of markets, economic activity and finally, the general price level.

Monetary policy influences real economy through financial markets; first, monetary policy decisions involve changes in financial variables (bank interest rates, exchange rates, the price of financial assets, etc.), which in turn lead to modifications of the real economy.

Central bank policy rate defines the starting point in highlighting the impact of monetary policy on real economy. Under normal conditions (no crisis or turmoil), interest rate fluctuations affect real economy and, ultimately, the price level through several channels, as summarized in figure 1.

Figure 1. The monetary transmission mechanism

Source: [1]

Under financial distress, monetary policy transmission mechanism can be affected by significant inefficiencies and even be blocked. If central bank policy rate falls to 0, we have a typical example. In this context, monetary policy can no longer influence real interest rates. Disturbances in the monetary transmission mechanism may also appear if the banking sector does not function normally, so that lending to the economy is significantly reduced or even discontinued.

The blocking of monetary policy transmission channels does not mean the incapacity of central banks to influence real economy. From this point of view, both academic literature and economic practice highlights the increased concern of central banks to design and implement certain monetary policy measures considered, in the light of recent events, as *unconventional* or *non-standard*.

Given the current financial tensions, *interest rate channel* efficiency is extremely important. As the money markets, along with other credit markets became increasingly interconnected over the past twenty years, the recent developments have attracted severe adverse macroeconomic consequences. Based on these premises, monitoring and evaluating bank interest rate pass-through is an essential aspect.

The present paper is structured as follows: second section points out the particular features of pass-through process in the context of the international crisis; the third one shows the impact of unconventional measures applied by the Eurosystem in order to support the functioning of monetary policy transmission mechanism; section four includes the final remarks.

2. Main features of bank interest rate pass-through in the light of the international financial crisis

Analyzing the *bank-based* Eurozone financial system, the extent to which central bank policy rate affects retail bank interest rate pass-through represents a fundamental aspect of single monetary transmission mechanism.

The onset of financial turmoil in mid-2007 generated an increase of credit risk premiums for interbank loans and a sharp decline of market transactions. Bank uncertainties regarding the creditworthiness of their counterparties extended rapidly [2]. By September 2008, when it became clear that financial system could collapse, the spread between 3-month EURIBOR and overnight index swap (OIS) with the same maturity displayed extremely high values (figure 2).

Since bank interest rates are determined and by LIBOR interest rates (EURIBOR in the euro area) and the latter are often used as

an index, they also increased.

The worsening of money market conditions has been reflected by the pronounced interest rates volatility, which made it difficult to measure and to evaluate the monetary policy position.

Figure 2. The spread between three-month EURIBOR and OIS (basis points)

Source: [3]

Note: End of week observation;

Latest observation: 11 February 2011.

As a result, the risk of severe deterioration of the transmission mechanism first line (defined by the connection between the central bank and credit institutions) appeared. Because a significant share of bank loans are carried out in the unsecured money market, spreads increase has had a direct impact on bank interest rates [4].

As a result of banks lower capacity to attract funds, credit standards applied to firms loans and credit lines have been considerably tightened [5].

In an economic environment where the monetary policy transmission channels have been significantly affected, the typical response of central bank, namely reducing ECB policy interest rate is insufficient to ensure the functioning of monetary transmission mechanism. In this context, it was necessary to implement some *unconventional* monetary policy measures, so that the next level of the transmission mechanism (from banks to households and non-financial corporations) to remain fully operational.

From the onset of international crisis, bank interest rate pass-through remained an efficient process, the immediate and most pronounced impact of the turmoil being

experienced by the short-term interest rates. The explanation lies in the deterioration of connections (normally closed) between overnight rates and term rates. This evolution has influenced the pass-through process due to the fact that short-term interest rates are often set depending on unsecured EURIBOR.

Analyzing short-term credit market, we notice a defective functioning of the transmission mechanism, especially during 2007-2008. However, between September 2008 and February 2010 short-term interest rates have declined by 341 basis points, while EURIBOR simultaneously decreased by 436 basis points, reflecting the lowering of ECB policy rate, alongside a number of measures applied so that money market conditions would gradually normalize (in March 2009, the levels hovered well below those recorded before the crisis). Long-term interest rates fell by 151 points, while 7-year government bond yields decreased by 121 basis points.

However, we can not completely exclude that interest rate reductions have also been influenced by a lower demand from households and non-financial corporations in the context of a deteriorating economic climate marked by increased uncertainty. Considering the cost of bank financing in nominal terms, Eurozone monetary and financial institutions (MFIs) interest rates for loans to non-financial corporations fell almost in parallel with the ECB policy rate (figure 3).

Figure 3. The evolution of Eurozone monetary and financial institutions short-term interest rates (% per annum, January 2007-November 2010)

Source: [6]

Most interest rates of consumer credit and for house purchase also fell, albeit to a lesser extent than the corresponding interest rate of loans to non-financial corporations (figure 3).

Overall, between June 2007 and May 2009, the monetary policy interest rate changes transmitted on long-term interest rates in a similar manner to that of previous, normality periods. In the second half of 2007 and 2008, long-term interest rates on loans granted to non-financial corporations have fluctuated over the estimated levels of pass-through models, reflecting the banks practice to set high rates in case of a large demand manifested in a period of increased uncertainty.

In essence, it is doubtful that the effects of monetary policy rate changes have been transmitted on long-term interest rates in a slower manner than before the international crisis occurrence. However, this observation must be addressed in the context of a lower credit demand from households and non-financial corporations, which diminished bank interest rate pressures.

Figure 4. The evolution of interest rate on new loans in the Eurozone (% per annum, January-2007-January 2011)

Source: [6]

However, the lowering of money market interest rates in the context of ECB policy rate reduction have been transmitted to bank interest rates on loans with a significant gap, in line with previous developments, reflected mainly by the expansion of spread between market interest rates and bank interest rates.

The empirical evidence indicating the evolution of interest rate spreads of loans to households shows that the increase points out

their higher risk levels compared to those under normal economic conditions.

A recent study ([7]) states that the current financial distress contributed to the increasing heterogeneity of pass-through mechanism in the Eurozone member states (table 1).

Table 1. Substantial differences across Eurozone countries both in terms of speed and degree of pass-through

Loans/ deposit category	Minimum speed of adjustment	Maximum speed of ad justment	Spread (min-max)	Standard deviation
Overnight deposits	-0.07	-0.78	0.72	0.22
Savings deposits	-0.01	-0.42	0.40	0.14
Short-term time deposits	-0.14	-0.91	0.78	0.24
Long-term time deposits	-0.10	-0.42	0.32	0.10
Overdrafts	-0.04	-0.93	0.89	0.25
Short-term consumer credit	-0.04	-0.85	0.81	0.24
Long term consumer credit	-0.07	-0.42	0.36	0.10
Short-term house purchase	-0.01	-0.44	0.43	0.12
Long-term house purchase	0.00	-0.26	0.26	0.08
Short-term loans to NFC	-0.21	-0.67	0.47	0.18
Long-term loans to NFC	-0.10	-0.87	0.77	0.23

Source: [7]

Note: NFC= Non-Financial Corporations.

The bank interest rate pass-through is an integral and important part of the monetary policy transmission. Evidence of a large degree of heterogeneity across euro area countries in terms of speed and degree of retail bank rate adjustment to market (and policy) rates points to a lack of integration of EZ retail bank market and to some asymmetric implications of single monetary policy that affects bank financing costs of the private sector.

During the crisis it remained completely operational, its functioning being similar to that of economic and financial stability periods.

The extent to which monetary policy transmission has been irreversibly damaged by the implications of the international crisis is still premature to determine. It can be argued that current efforts aimed at establishing a more comprehensive and solid regulatory framework in order to strengthen the banking sector flexibility offers it the opportunity to have a more stable role in the monetary policy transmission.

3. The impact of Eurosystem's unconventional measures on the monetary policy transmission

The recent global financial tensions and the subsequent economic downturn have resulted in unprecedented monetary policy reactions of the monetary authorities. Thus, on 8th October 2008, the European Central Bank, the Federal Reserve and the Bank of England and three other major central banks have simultaneously announced a 50 basis points reduction of their policy rates. This coordinated action undertaken for the first time in history highlights the strong commitment of the central banks international community reacting to the profound macroeconomic implications of the financial markets crisis [8]. After the turmoil erupted, the sharp deterioration of macroeconomic indicators and the inflation rate (as a result of oil and raw materials falling prices), lead to further actions of developed countries central banks that significantly and repeatedly lowered their policy interest rates, (currently the latter range between 0 and 1%).

Figure 5. Evolution of key policy rates in the Eurozone, United States and Great Britain (percent per annum)

Source: [9]

Taking ECB as reference, it is noteworthy that after the collapse of Lehman Brothers, from October 2008, it gradually reduced the monetary policy rate by 325 basis points, from 25% in April 2008 to 1% in May 2009, level maintained even today and considered the lowest since the creation of EMU. However, financial tensions have detained the transmission of policy rates changes on money market interest rates and subsequently to bank interest rates.

In this context, the lowering of EZ interest rates to values that had not been recorded for decades has been accompanied by the Eurosystem design and implementation of a set of unconventional monetary policy measures aimed at *sustainable lending (enhanced credit support)* and the *correction of securities market failures (Securities Markets Programme)*. Such actions include:

a) the adoption of a fix rate tender procedure with full allotment used for the regular monetary policy operations in order to stabilize the banking sector in a period of high financial stress. By introducing this measure, the Eurosystem intended to support short-term banks financing so as to mitigate the potential negative impact of liquidity risk on credit availability for households and non-financial corporations;

b) the provision of liquidity in foreign currencies (in particular USD and CHF) to correct the failures of associated interbank market;

c) the broadening of eligible collateral by including securities (other than asset-backed securities-ABS) with BBB or higher rating, and the increase of exceptional operations average maturity;

d) the extension of long-term refinancing operations with a three-month maturity to one year maturity in order to reduce banks short-term refinancing needs. In the pre-crisis period, Eurosystem used only main refinancing operations (MROs) with one-week maturities and longer-term refinancing operations (LTROs) with three-month maturities.

e) covered bond purchases, euro-denominated and issued in the Eurozone. Based on such operations, Eurosystem facilitated the continuing decline of money market interest rates, eased the funding conditions for households and non-financial corporations, enlarged the loans volume and improved the liquidity of certain important segments of the private sector debt market [10];

d) interventions in the Eurozone public and private bond markets, based on securities market programme (SMP). Under SPM, the Eurosystem can act directly on the euro area public and private debt securities markets to correct the potential failures and to restore the normal operation of monetary policy transmission mechanism.

Analyzing the transmission of ECB policy rate, we find that the functioning of government bond market constitutes an essential factor. This is because of several channels, as follows [11]:

✓ through the *prices channel*, the interest rates of government bond influence the economy financing conditions. If the bond market functions normally, the state financing conditions provide a floor for the private sector financing terms.

✓ *liquidity channel*; government bonds are often used as collateral for banks refinancing operations;

✓ *the balance sheet channel* is indirect; for example, the decrease of bond prices corresponding to higher yields involves the lowering of assets value held by financial and non-financial sectors.

In the context of the current crisis, the unconventional monetary policy measures implemented by central banks have mainly aimed to restore the normal functioning of monetary policy transmission by improving market liquidity and sustaining their functioning.

Also, through these measures, central banks have tried to support, to a greater extent than it would have been achieved only by reducing policy interest rates, credit flows to the real economy, market by a significant contraction.

Figura 6. The evolution of loans growth rate* in the Eurozone and in the United States (January-2007-September 2010)

Source: [12]

Note: *year-on-year, per cent.

Despite an overall positive impact of non-standard policy measures, bank lending remains low, much lower than before the crisis (figure 6) mainly due to the perception of banks' credit risk and the uncertainties regarding future developments of economic climate.

The unconventional monetary policy measures have a temporary nature and must be used only under financial distress. Thus, as the functioning of financial markets and of the economy, in general, improves, they are no longer justified.

Financial market indicators, the risk premia and monetary indicators, especially inflation expectations and the changes in money and banking have an important role in deciding the best moment to remove the non-standard policy measures.

4. Conclusion

Overall, except for some differences between the euro area countries, pass-through mechanism has functioned properly, meaning that retail bank interest rates and money market interest rates do not significantly differ from patterns displayed in previous years. This process was operational even in

the peak periods of the international crisis and respond appropriately to EURIBOR and long-term rates movements, albeit with some problems in relation to the EONIA, due to the strong tensions of the interbank money market.

By using unconventional policy measures, central banks tried to avoid the blockage of the financial intermediation process and to ensure an effective transmission of monetary policy to the real economy.

Currently, the main challenge for the central banks is the receding of the unconventional measures application as a response to financial markets tensions. By abandoning such measures, ECB aims to return to the normal course of monetary policy, which means using the refinancing operations with a one-week maturity as a main instrument for managing interest rates, market liquidity and indicating the monetary policy stance.

The present global economic crisis has highlighted the importance of monetary policy transmission mechanism and the soundness of financial system to ensure the efficiency of monetary policy.

Considerations Regarding the Managerial Competence

Roșca Constantin
University of Craiova
rosca2na@yahoo.com

Abstract

By the present study, the authors bring into question three important aspects of the professional competence.

The first aspect refers to the fact that obtaining by studies a professional competence must be based on or start from the genetic background of general organization of the human brain, that is from the native abilities/skills and aptitudes of the individual.

The second aspect, developing the above-mentioned idea, emphasises the causal report between knowledge, behaviour and performance. Only on the innate skills there can be set the sound knowledge, create skills and form acting behaviours adequate to the profession with purposeful emotional personal satisfaction and genuine professional performance.

The final part of the article deals with the specific features of the managerial competence closely linked to the triple meaning of management as a science, art and mood.

Key words: competence, aptitudes/skills, professional knowledge, acting behaviour, performance, management

J.E.L. classification: L20

1. Argument

Considered as a determining factor in the success of the activities carried out by an individual, the professional competence, by its social significance and usefulness, is a theme always current and contemporary and very exciting for the specialists in education in terms of defining the concept, but especially of the insurance of its content through the formative process, but also for the educational product recipients or beneficiaries, the practitioners who find the

existence and driven manifestation of the competence which is expected.

The hidden qualitative feature of an individual, which manifests itself in the carrying out of the activities through motivations, character traits, personal opinions, attitudes, knowledge, cognitive and/or behavioural, the professional competence is achieved through education or studies. The diplomas issued by authorized institutions confirm the formation or development of skills for a profession or another. By mentioning what knows, what is able to do the graduate, these diplomas represent for the owner a preliminary condition for occupying a specific function and prefigures a possible success in life, by anticipating the professional performance.

2. Theoretical considerations

Through syntactic constructions of the phrase specific to the each author's style of expression, as well as through the degree of detailing the ideas, specialists in charge of the study of the competence concept highlight the following defining components:

- „set of knowledge, skills, behaviour types, standard procedures and types of reasoning that can be used (immediately) without learning something new" [4];

- „theoretical knowledge, procedural knowledge (that prescribe how to do), procedural skills (i.e the practical application of the procedures), skills developed from experiences, social skills (manifested, for example by the argumentation and negotiation skills), cognitive skills (that refer or relate to mental operations)" [3];

- „knowledge, skills, the self-image (given by the self-confidence), personality traits, motivations" [6];

- „hard competences appropriate to the knowledge and skills, and soft competences,

appropriate to the self-image, to the personality and motivations”[6];

- „, the assembly or set of the factors and conditions that relate to the general organization of the human brain, so as to cope with and respond appropriately and adequately to the demands of the internal and external environment of the body”[1].

The definitions presented focus on two components of the competence: knowledge and behaviours. The professional knowledge and acquired skills as a result of the school education and the gained one through the practical experience in exercising the function are those that confer some degree of intellectual organization to the human brain. The behavioural component consists in the way to act/work in different professional contexts by applying the most appropriate procedures, reflecting the way in which the human brain, through its degree of organization, succeeds or fails to meet the demands of the profession.

In order to confer a comprehensive definition to the competence, we consider that it should be taken into consideration a third component, that is, in some cases more implicit in the selected formulations for comparative analysis and by no means explicit. This component that should not be absent from the definition of the concept, is that it represents, actually, the foundation on which there are set the knowledge and formed the professional behaviours, namely, **the native skills**. It is widely known the fact that the individual are born with a certain predisposition for a certain field of activity or for a certain profession. The professional performance, as well as the personal satisfaction, for the work well-done, as forms of expression of the acting behaviour, is much larger and fuller, the more the component of professional knowledge is grafted on vocation, on the innate skills. No matter how much speciality knowledge would be passed through to an individual who by birth has the vocation of shoemaker, it is hard to believe that he could do or make performance as a philosopher or virtuoso violinist, for example.

In this way we consider that a definition of the competence might be formulated in the following terms: *the competence represents that intrinsic qualitative trait or feature of an individual who, based on its*

native skills, consists of a set of knowledge and skills acquired through school education and practical experience that confers to the human brain that way of general organization that, responding more adequately or appropriate to the demands of the profession, allows to have a performing and efficient professional behaviour.

Put in a mathematical expression, the individual competence (Cp), is of the following form:

$$Cp = \frac{\sum_{i=1}^n X_i}{\sum_{j=1}^m Y_j}, \text{ in which:}$$

$\sum Y_j$ represents the possible problematic situations specific to the profession;

$\sum X_i$ represents the multitude or set of responses that the individual can give to these problematic situations of the profession.

Ideally, the maximum competence would correspond to the relationship:

$$Cp_{\max} = 1$$

Since this maximum competence limit cannot be achieved or reached by the human brain, it is important to note and remember the fact that the sub-unitary value of this report expresses the *possible behaviour*, which reflects, in fact, *the individual competence*. It is the result of the information and the storage of theoretical information (the result of the professional education) and practical (the result of the work experience) filtered in advance and adapted as response, to the specific requirements of the profession. This is the reason for which, in practice, the individual competence is always situated below the level of the maximum competence, that is:

$$C_p < 1$$

3. The competence – performance relationship

Between skills, expressing *the possible* behavioural and performance, that reveals *the real* behaviour of the individual, there is a causal relationship: the competence is a premise for performance, and performance expresses the effect of the competent behaviour in exercising the function, so that

knowledge, competence and performance form by inter-conditioning a dialectical unity based on the native skills.

Knowledge grafted on skills, acquired and developed continuously by research or studies and experience, determine the competence; the competence as a source of the possible professional behaviour, during the carrying out of the activities and work determines performance; in its turn, the performance enriches knowledge with new information of a great intensity, generating innovation.

For example, in the business field, the potential possible behaviour based on solid professional knowledge and strong character traits predicts the entrepreneurial behaviour depending on the strategic options and policies adopted, by the way of acquisition of the targets and objectives, by the choice of methods and procedures for action, risk taking and responsibilities. This behaviour leads to a continuous improvement of the staff, to the constant enriching of the quality, to the increase of profitability, to the development through innovation of new products and services.

The power – performance causal pattern, provides the managers, among others, the means of assessing the "risk" in the assessment of the candidates for employment, but also especially in the career development. The risk of assessment of a person who, although he/ she has the necessary training or professional preparation, but has not the professional vocation, has no serious motivation of work leads to lower work performance, to the competitive behaviour disturbance and to the reduction of the capacity for innovation.

The management practice has shown that although it is difficult, it is not impossible to intervene to change attitudes and values of an individual, the motivation in his work, the way of thinking that leads, directs and selects the individual's behaviour through specific means of the organizational culture to change the traits of character.

4. The managerial competence

The management is a profession like any other, being carried out by individuals who, belonging to a particular or special socio-professional category, are endowed with the

ability to organize and manage an enterprise in an innovative spirit and expansionist. Long before being used in business or economic field, the management concept was used in the field of politics, journalism and public administration, having specific ways to find out, for example, if a politician was appointed to the best or most appropriate position, depending on his skills and training. Irrespective of the field of activity and scope of duties assigned in the organizational hierarchy, the qualities of a real manager are focused on dynamism, large initiation to knowledge, communication and adaptability.

By meeting the same basic/definition elements such as professional competence, in general, the managerial competence, through the content of its defining components, it wears certain specificities closely related to the triple significance of the management as science, art, state of mind.

Thus, the scientific component of the managerial competence is expressed through initial and continuous education acquisition of an organized and coherent set of knowledge (concepts, principles, methods, techniques and management instruments) and the formation of behavioural skills oriented towards the achievement of the company strategy and policies through the rigorous organization of carrying out the activities, the systematic analysis of their success and failures, in order to validate the positive experience in the field, to improve the existing management methods and techniques and to add some new ones.

Without the field-specific knowledge base, the practiced management process is based on intuition, the so-called personal flair and improvisation that are an unprofessional one, with consequences manifested unquestionable sooner or later on performance.

The component of „art” of the managerial competence is based on the manager's personality, on his ability to behave with people, with the employees and business partners: clients, suppliers, creditors etc. Through this prism, the managerial competence is manifested as a skill that is different in relation to vocation, talent, and the manager's personality traits expressed by:

- The personal capacity / ability of the manager to ensure the profitability of the a organization that he leads,

- The managerial responsibility for guiding the objectives, the allocation and use of the resources in order to achieve the best possible results;

- Organizing the staff's work and its motivation in order to obtain an adequate or appropriate productivity, by taking into account the employees' aspirations and the fulfilment of the social function of the organization.

By the component of „art” of the managerial competence it is emphasized the leader's skill to assert his managerial skills that he applies to the realities of the organization in efficiency conditions.

The specific managerial competence mood is reflected in a certain way of looking at and addressing the issues related to the management process in a concrete way to wish, search, find, accept and implement progress, a concrete method to manage in a dynamic vision directed to a well-defined goal, namely to maximum efficiency. The formation of a new organizational culture that should focus on a behaviour and responsibility for the assumed work, to promote the new, the creativity, the innovation, constitute the essence of a mood based on the manager - employee communication, on the achievement of a genuine partnership between management and social actors, the promotion of the participatory management

5. Conclusions

The professional competence, irrespective of the activity field and of the hierarchical level to which it is exercised, is a synthesis between innate abilities/ skills, developed through the acquisition of knowledge and behaviours formed through a lifelong learning process, dynamic and cumulative. It is manifested through action and is maintained only by action in the exercise of the assigned or entrusted function. It is important to remember that it has a volatile nature: when competence is not activated, it disappears.

Abstract

In the present study, the authors refer to the methodological landmarks that led to the organization and the COMOR project development for the research of the managerial behaviour in the organizations from Romania. In this respect, there are described:

- The procedures for establishing the research sample;

- The contents and characteristics of the questionnaire used for the data collection on value judgements about the forms of manifestation of the dimensions of the organizational culture;

- The dissemination procedures of the research and of the field data collection;

- The categories of statistical-mathematical indicators used as analysis supports;

- Ways of exploiting the conclusions obtained from the analysis of the results.

Key words: scientific research, methodology, sample, value judgements, opinion, item, evaluation, scale of values, analysis indicators

J.E.L. classification: C81, L26, M10

1. Preamble

COMOR is the acronym of the research project of the managerial behaviour in the economic organizations from the Romanian space, initiated in the year 2008 by the Scientific Society of Management from Romania – SSMAR.

This exploratory research is carried out according to a proper/own methodology designed to ensure the completion of its

phases and stages in a systematic and uniform way and in compliance with the scientific requirements from the field, in such a way that through the data processing and the proper analysis of the supplied information, realistic conclusions could be drawn that can allow:

- The knowledge of the managerial behaviour in different types of economic organizations from Romania;

- The comparative analysis of the elements that characterize the organizational culture from the different counties of the country and areas of economic activity;

- Verifying the measure and way in which the dimensions of the organizational culture and the managerial behaviour from the Hofstede and GLOBE patterns (Global Leadership an Organisational Behaviour Effectiveness) are found in the organizations from our country;

- The identification of the personality and behavioural traits and the efficient manager and of the leader of excellence.

The research methodology was completed through several rounds of discussions and debates on workgroups with the participation of teams composed of academics and și business representatives from Craiova, Bucharest, Timișoara, Târgu Mureș, Oradea, Suceava, Constanța, Cluj Napoca, Galați, Brașov, Târgu Jiu.

The main issues for discussion and debate referred to:

- The stability of the sample to be studied;

- The development of the instrument of measuring the opinions;

- The organization of data collection;

- The processing of the data collected from the field;

- The exploitation of the research results.

2. The Sampling

The starting point in our research consisted in the determining the statistical units (of observation) on the one hand, and of the survey units, on the other hand. In both cases, it was conducted a stratified sampling, in such a way as to ensure a more detailed and eloquent representation of the opinions expressed about the various investigated aspects. In order to determine the statistical units of which there were selected the respondents, there were decreasing in number three layers, as it follows:

Layer 1. From the list of all the economic units that deposited to the county chambers of commerce and industry accounting (balancing) statements until 31st of December 2008, it was formed a first layer of the units that had a number of at least 50 employees.

Layer 2. For each county, on the basis of algorithm, out of the number of units that have at least 50 employees, it was established number of units that are going to be studied, by drawing up their list.

Layer 3. From the list formed in the layer 2 there were chosen the representative units for the economy of the county, on areas of activity according to NACE code. The list was finalized only after the management of the units concerned agreed to participate or take part to the research.

The establishment of the survey units (the respondents) took place in more steps in their passage through other six different layers, as it follows:

Layer 4. For each economic unit established in the layer 3, with the help of an algorithm, it was established the approximate number of respondents, depending on the total number of employees within the respective unit.

The following steps took into account the nomination of the respondents by the distribution of the number established in layer 4, depending upon:

- The type of activity carried out or performed within the organization (*layer 5*: production, administration, marketing, research, development, financial accounting);
- The hierarchical level to which there are the respective persons (*layer 6*: top managers, middle managers, managers from the base, performers);

- The sex and the age (*layers 7 and 8*);The level of the studies (*layer 9*: higher education, medium studies, elementary education)

3. The measurement of the opinions

• *The Structure of the questionnaire*

For the data collection, COMOR project used a complex questionnaire, within which the items were structured into six distinct segments according to the intended purpose or goal by obtaining responses as it follows:

1. The sheet/ record of the organization that contains identifying information of the statistical observation unit: the name, locality, county, NACE code, the date of establishment, type of organization, form of ownership upon the social capital, the main economic indicators, the staff structure.
2. General information of identifying the respondent: the hierarchical position held by the respondent; the sex, the age, the marital status, the level of the studies, the managerial training or formation, the field of activity in which he/ she works etc.;
3. Value judgements that should allow the characterization of the dimensions of organizational culture ;
4. Opinions regarding practices of organizational behaviour;
5. Value judgements regarding the profile of the efficient manager;
6. Value judgements of the excellence leader.

In order to ensure the proper and correct understanding by the respondents of what we intended by the research undertaken, each segment of the questionnaire is prefaced by short information with methodological character (content) and/or how to complete the expected responses.

We mention that there were set or established in a very explicit way:

- The voluntary nature of participating to the survey , in the sense that the requested or solicited person may accept or not to be part of the sample, as well as the fact that he/she can answer all the questions of the questionnaire, or only to some of them;
- To ensure the anonymity and the confidentiality of the expressed opinions.

- *The Typology of the questions*

The questionnaire contains closed questions as well as open questions. The closed questions are factual questions that refer to the identification of the observation unit, as well as of the respondents. The close questions are abstract questions, through which the respondents are requested to make judgments of value and/or to express opinions regarding the investigated aspects.

Since it cannot be drawn a conclusion regarding the people's opinions and attitudes by analysing the answers to only one question, there have been made some sets of questions which should allow the establishment of the position towards the problem investigated.

Thus, "the distance from power", as dimension of the organizational culture is being characterized by several forms of manifestation, among which we can include: the stated hierarchy; the people's behaviour towards hierarchy; the mood or state of mind from the organization etc. In order to ensure a much more real and comprehensive characterization of a certain form of manifestation, there were formulated batteries of questions. Thus, for the characterization of the stated hierarchy there were formulated five questions, of the privileges offered by the hierarchy three questions, the mood or state of mind existing in the organization seven questions and so on.

As the carried out research pursues a double purpose, the shooting of the existing situation, but also the identification of some future projections, each question asks the respondents to express their views and points of view in the two situations.

- *The rating/ evaluation scale*

In order to express the intensity of the attachment, agreement or disagreement to the investigated aspects, the rating/ evaluation scale of the answers covers the entire spectrum of opinions:

- From intensely or highly positive to intensely or highly negative, with the intermediate steps: total agreement, partial agreement, indecision, partial disagreement, total disagreement, respectively,

- From the total acceptance – Yes, to the total rejection – No.

4. The data collection

In order to collect the data from the field, the investigation operators were university teachers or academics, who also used the extemporal method (for the persons with elementary and secondary education), as well as the self- management method applied to the ones with higher education and to the managers.

5. The data processing

The stage of the processing of the field data with the help of the questionnaire are based on its own IT/software program that allows:

- The creation of a database;
- The tabular of the summary statements;
- The calculation of the econometric analysis indicators.

The database is made up or consists of the centralized processing at the level of the statistical observation units of the data obtained by completing the questionnaire by the respondents from the sample.

Starting from this level of taking of data in the next phase it proceeds to the tabular combined concomitant multi-criteria, on counties, development regions and national economy, for each dimension of the organizational culture, forms of manifestation of the managerial behaviour, characteristics and behaviours of the efficient manager and of the excellence or effective leader.

For the descriptive and factorial analysis of the elements that characterize the organizational culture, in the research framework it was established the system of indicators composed of indicators of position, of the central tendency, of variation and correlation.

With the help of position *indicators* (*percentage shares*) that are relative sizes, of structure, are characterized by:

- The representativeness of the sample (the degree of trust given to the given answers), reflecting the structure of economic units subject to research, on areas of economic activity, according to the size degree and the form of ownership of the social capital;

- The reliability or degree of trust of the value judgements/opinions expressed by the respondents, on different social variables

(sex, age, studies, hierarchy), for each item that characterize the dimensions of the organizational culture and the managerial features.

In order to calculate the other indicators it was done, in advance, the conversion of value judgements in numerical expressions on scale of values with 5,3 or 2 levels of the spectrum of opinions, as it follows:

- On the scale with 5 levels, the conversion led to the following correspondences:

Total agreement, value	5
Partial agreement	4
Indecision	3
Partial disagreement	2
Total disagreement	1

- On the scale with 3 levels:

The agreement, value	3
Indecision	2
Disagreement	1

- On the scale with 2 values:

Yes, with value	1
No, with value	0

As indicators of the central tendency, in the COMOR project is used: the average value, the median, mode, asymmetry coefficients. The interpretation of these indicators allows us to highlight the essential trends of the variability of the answers given to the questions from the questionnaire.

The variation indicators allow characterizing the homogeneity degree or of spreading the opinions expressed at the level of the company, county, development region, as well as on social structures of the respondents (sex, age, education, hierarchy). In this group of indicators we can distinguish simple indicators of variation (the amplitude of variation and the individual deviations from the average calculated values) and synthetic indicators of variation (standard deviation and the coefficient of variation).

Within the COMOR project we are dealing with factorial correlations highlighted by the following indicators of co-measuring of the intensity causal connections between the factorial variables (behaviours, character traits etc.) and the variable outcome (the dimension of the organizational culture): the correlation table, the graphic method, the regression coefficient.

6. The analysis and exploitation of the results

According to the methodology, the research results are analyzed on levels of aggregation (large organizations, counties, development regions, national economy). The development is going to be made by analysis reports addressed to the decisional governing bodies at the above-mentioned levels, by exposures to scientific meetings, publishing of articles in professional journals or speciality magazines, editing books on the topic of the organizational culture in the Romanian culture and space.

In conclusion, we consider that the completion and ending of the COMOR project is going to be a modest contribution to the promoting of indigenous scientific research in the field of the organizational culture and the affirmation on the scientific international level /plan of the Romanian school of management, by providing the decision-makers useful information for business development in the context of globalization.

Abstract

In the context of economic globalization, the scientific knowledge of the managerial behaviour from the economic organizations that carry out their activity in different geographical areas of the country, it represents a way to prevent poor performance or even failure in business. The COMOR project, launched by the Scientific Society of Management from Romania has as purpose the identification of the cultural dimensions that characterize the organisational management from our country by knowing:

- The effects that the national culture, or its subcultures, exercise upon the organizational practices and the managers' behaviour;

- The managers' perception and the execution staff's perception on leadership;

- The dominant features of the cultural dimensions that characterize the organizational management in all the counties of Romania and in the most representative areas of economic activity.

In the present material or paper there are presented the results of the preliminary analysis of the way in which it is manifested the „individualism – collectivism” and the „masculinity – femininity” in the organizations of Suceava county.

Key words: the organizational culture; dimensions of the organizational culture; individualism – collectivism; masculinity – femininity.

J.E.L. classification: C81, L26, M10

1. Introduction

The study of the organizational culture in Suceava county is a component part of the COMOR project that is researching this topic at a national level, by investigating the phenomenon in all the counties of the country. We mention that for Suceava county 222 respondents expressed their views and points of view out of 15 companies with activity carried out in trade (5 units), the manufacturing industry (4 units), construction (2 units), tourism (2 units), mining industry (one unit) and the water supply/ distribution(one unit). The respondents are distributed on social group variables as it follows:

- by gender/sex: 150 men (67,6%), and 72 women (32,4%);
- by age: 39 young people under 30 years old (17,6%), 174 persons having the age between 30 – 60 years old (78,4%) and 9 persons having the age over 60 years old (4,0%);
- by studies: 111 persons with secondary education and 110 with higher education;
- by hierarchy: 81 managers of all organizational levels: 4 top managers, 21 middle managers, and 56 from the basis (36,5%) and 141 executives (63,5%)

In the present article we are going to present an analysis only for two cultural dimensions: individualism – collectivism and masculinity – femininity. This segment of the research is constituted as pilot- study subject to a wide debate in the project work groups within COMOR, following to be developed and improved by the suggestions and critical comments and observations of those

concerned or interested. As a quantitative indicator for measuring the intensity of the opinions expressed by the respondents, we are going to use the medium values of the scores calculated for the most significant forms of expression / manifestation of the two cultural dimensions mentioned above.

2. Individualism – collectivism

This cultural dimension is based on the relationship between individuals and the way in which the organization, through its culture, encourages the individual or the group interests.

Where the individualism is high, the connections and relations between people are weak (confused, superficial and temporary), each carrying out about himself, while the collectivism emphasises the group, on good confidence in the team and on the decisions adopted by the group, on the devotion towards the organization.

Furthermore, we are going to present the specific forms of manifestation of this cultural dimensions highlighted by the development of the COMOR project in Suceava county. The data analysis and interpretation is based on the significance of the scores calculated for the opinions expressed on the scale with 5 values: from intensely positive (5), to intensely negative (1) of the value judgements as answer to the questions from the questionnaire.

Judging the opinions of the respondents by the size of the calculated scores on the two adverse features, individualism – collectivism, (table 1), we conclude that in the organizations from Suceava it prevails the collectivism both in the current situation (average score 4,053, as compared to the individualism's score – 3,665), as well as in the future projection of this economic entities (4,554 the score of collectivism, as compared to 3,626 the score of individualism).

Table 1
The Scores of the main forms of manifestation of the dimension „Individualism – collectivism” (Preliminary results)

Forms of expression of the cultural dimension „Individualism – collectivism”	Scores of the opinions according to the practices		Trend individualism (I) or collectivism (C)
	Existent	Wanted	
Decisional authority of the - managers - managerial bodies	4,590 3,838	4,086 4,806	I ↘ C ↗
Methods of organizing work oriented on - individual work - team work	2,428 4,099	2,311 4,833	I ↘ C ↗
Practices of wage motivation oriented on - the personal interest' s stimulation - the group interest' s stimulation	3,872 3,570	3,844 4,360	I ↘ C ↗
The employees' dependence to hierarchy - unconditional acceptance of the decisions - criticizing the decisions	3,026 4,721	3,401 4,932	I ↗ C ↗
Favours of the hierarchical position	3,104	2,666	I ↘
Personal aspirations	4,108	4,473	I ↗
Involvement in the settling of conflicts - by managers - by the members of the group	4,527 4,079	4,599 4,266	I → C ↗
The attachment to the organization - of the managers - of the employees	4,234 4,052	4,509 4,281	C ↗ C ↗
Satisfaction towards the group achievements	3,833	4,446	C ↗
Average score for - collectivism - individualism	4,053 3,665	4,554 3,626	↗ ↘

The scale values: 5 – intensely positive;
1 – intensely negative

Mainly in the forms of manifestation of the organizational culture, the **collectivism** is present by:

- practicing a participatory management that confers/gives decisional authority to the management bodies;
- the people's preference to work in team, focusing on the group cohesion accompanied and sustained by policies that stimulate and enhance the group interests;
- the attachment or commitment to the organization that provides safety and stability in the workplace;
- cultivating some close relationships between people based on attitudes and behaviours of kindness, tolerance and compassion for the joys or sorrows of the people;
- confidence in the group calling for help to the others professional issues, but also the improvement of the interpersonal relations (involvement in the settlement of tensions or conflict states or moods);
- freedom of expression through the criticism of the managerial decisions as well as by the possibility of the employees to choose the most appropriate methods of work in order to fulfil the tasks.

It is worth mentioning the fact that in perspective it is intended that the values of collectivism to be stronger supported and developed, while the individualism values to remain at a relatively constant level, yet with a slight downward trend.

On the background of moderate collectivism (average score 4,053) in the units from Suceava county there are also present forms of individualism embodied in the decisional authority of the managers and the severe addiction of the subordinates to the bosses' decisions, individual aspirations, the stimulation of personal interests, the existence of some favouritisms, the authoritative involvement of the managers in the settlement/settle of certain tensed/conflict states or moods.

3. Masculinity – femininity

The degree of masculinity or femininity at organization level implies some behavioural characteristics with orientation towards some material values based on offensive strategies and politics.

Where *masculine values* predominate, there are specific the offensive strategies and policies that gives to the organization an emphasised dynamism centred on immediate outputs, measurable (profitability), there are practised hierarchical organizational structures with excessive centralization of the decisions and growing authoritative management in which it is cultivated the determinant role of the managers and the hierarchical subordination. The division of roles is made discriminatory in the favour of men, the women are marginalized in secondary roles, the staff training is based on material motivations differentiated by post, sex, preparation/education, experience, and the control is highly formal, rigid and focused on the tasks fulfilment.

In the organizations with a *high femininity index* the focus is on the belief in sex/gender equality, with a democratic management in which the strategic plans, less offensive, are focused on the company, being pursued the competitive enduring advantage by approaching the results in terms of humanistic values (the environmental preservation, the quality of life, the concern for the others), focalization on the organizational culture, the organizational climate, interpersonal relations. The training is based on a balance of the material and moral motivation.

For the organizations from Suceava county, the COMOR research highlights the various forms of expression of the cultural dimension „masculinity – femininity” presented in table 2, together with the intensity of their manifestation. The location of scores below or above the average value of the calculated scores allows us to draw conclusions about the prevalence of one or another of the values of the complementary – adverse: features masculinity or femininity.

Thus, among the *traditional masculine values* there are observed:

- The rigorous or thorough organization of the activities based on standards and performance indicators with detailed instructions on how to obtain the established or stated objectives;
- The ostentatious encouragement to performance, accompanied by the ambition of accomplishing the objectives to the set/established parameters, attitudes and behaviours that ensure the haloed image of

the winner, the performer's victory or glory once with significant financial rewards are strong in the existing situation and there is the desire to develop them in future projects;

- The egocentrism with male valences present by encouraging the people's desire to be strong by the positions they occupy in the organizational hierarchy, dominant towards the others;

- Practices of custody of the job and of wage motivation that are not related to performance, being based on seniority, sympathy feelings and emotional relations, political interests, business or family interests .We must mention that these values , although disavowed (score of only 2,383), have the tendency of cultivation in the future (score of 2,572), which reflects the people's dependence on mentalities not complying with the principles of a modern society in which the human personality and professional competence to assert themselves freely and without artificial barriers.

The main forms through which the *traditional feminine values* are expressed consist of the following:

- the promotion of humanistic values with an emphasis on the concern for the people by: the trust given to them to choose the most convenient methods for the carrying out of the work tasks; the material and moral stimulation of the performance; the cultivation of the team spirit and loyalty towards the group; promoting new strategies of human resources based on the creation of the lifelong learning culture; promoting a consensus in the interpersonal communication process and of negotiation of interests;

- concern about the company's interests by: promoting change as a state of normality in the design and implementation of activities adapting flexible structures of organization and management; the adaptation of the cultural organization to the European integration needs and economic globalization; the adoption of new marketing strategies meant to promote new products and services or to penetrate on new markets; the adapting of the style and management methods to the organizational dynamics and the training of successors to ensure the competitive lasting advantage to the organization.

Table 2
The Scores of the main forms of
manifestation of the dimension „masculinity
– femininity”

<i>Forms of expression/manifestation of the cultural dimension „masculinity – femininity”</i>	<i>Scores of the opinions according to the practices</i>		<i>Trend of masculinity (M) or femininity (F)</i>
	Existent	Wanted	
The desire for glory, honour shown by managers through	4,174	4,539	M ↗
- The ostentatious encouragement towards performance	4,311	4,721	M ↗
- The ambition to achieve the objectives of the organization			
Egocentrism manifested by the people's wish to be strong, dominant	4,390	4,539	M ↗
The organizational hierarchy reflected in	3,746	3,410	M ↘
- Employment opportunities for managerial positions	3,784	3,662	F
- The percentage (share) of women managers	3,416	3,301	M ↘
- Gender discriminatory practices			
The wage motivation is oriented towards	3,908	4,275	F
- performance	4,518	4,108	M ↘
- performance and other factors	2,383	2,572	M ↗
- other factors			
The role of the managers expressed through	4,113	4,545	M ↗
- the rigorous organization	4,081	4,625	F ↗
- the encouragement for quality and efficiency	3,613	4,194	F
- the support of the initiative, loyalty and training of the successors	4,101	4,679	M ↗
- the creation of conditions for an efficient carrying out of the activities	4,356	4,595	
- achieving the set /established objectives			
Interpersonal relations expressed by	3,833	4,446	F ↗
- the manager's behaviour	3,790	4,114	F ↗
- the employees' behaviour			
Average score for			
- masculinity	3,934	4,037	↗
- femininity	3,873	4,285	↗

(Preliminary results)

The scale values: 5 – intensely positive;
1 – intensely negative

In conclusion, the dominant feature of the organizations from Suceava is the masculinity. It remains and maintains itself as a future orientation, with a slight increase trend expressed by the value of the score of 4,037 as compared to the existing one of 3,934. It is to be noted the fact that the feminine values are the ones to which the respondents give a higher credit in the future (the desired score of 4,285, as compared to the actual score of 3,873).

Customers' Perceptions Regarding Channel Innovation in the Retail Banking Sector: a study on Internet Banking in Romania

Roșu Anca Maria
Academy of Economic Studies, Bucharest
anca.rosu@yahoo.com

Abstract

The banking industry has undergone significant operational changes over the last decade, thanks to advances in information technology. The rapid diffusion on the Internet has revolutionized the delivery channels used by the financial services industry.

This article examines consumers' perceptions of Internet Banking. A survey of bank's customers on Internet Banking in Romania revealed that familiarity in using computer and new technology has been found to positively affect consumer attitudes with regard to usage of electronic banking, as well as online banking adoption.

Users with lowest Internet banking experience use only the basic functions of this service. This group tends to be young in age and has the lowest income. Their income is expected to rise with age, and banks could enhance auxiliary features. These findings may provide useful guidelines for developing Internet bank services and for marketing Internet banking.

Key words: Internet Banking, customers' perceptions, innovation, retail banking, marketing strategy

J.E.L. classification: G21, L86, M31

1. Introduction

Innovation is positively related to firm performance (Goosen et al., 2002; Rauch et al., 2004). Managing multiple distribution channels is now a key strategic challenge for retail banks (Bruce et al., 2009; Capgemini et al. 2008).

The retail banking sector is currently struggling as it comes under greater competitive pressure from customers which

are becoming more demanding (Accenture, 2008) and non-banking organizations that are increasingly entering the marketplace to compete for customers (Deloitte, 2008). In this increasingly competitive marketplace, banks must differentiate themselves through innovative products and services.

A key area of strategic importance for retail banks is distribution channel management (Bruce et al., 2009; Capgemini et al., 2008).

The importance of the Internet in today's competitive and increasingly global banking environment has been widely acknowledged (Bauer, Cologan, 2001; Li, 2001; Thorton, White, 2001).

Together with the increasing rate of Internet and mobile services penetration, bank service providers have been constantly adapting to these changes, and at the same time they have met consumers' requirements with new services. The core of banks new strategic orientation currently consists of developing new alternative for the distribution channels for their traditional services (Moga, 2011).

Electronic banking services or E-banking is now a global phenomenon. It is an invaluable and powerful tool driving development, supporting growth, promoting innovation and enhancing competitiveness (Kamel, 2005; Nath et al., 2001).

Technological innovations have been identified to contribute to the distribution channels of banks (Goi, 2005). The evolution of banking technology has been driven by changes in distribution channels: ATM, Phone-banking, Tele-banking, PC-banking, Internet Banking (Chang, 2003; Gallup Consulting, 2008).

A strong banking industry is important in every country and can have a significant effect in supporting economic development through efficient financial services (Salehi, Alipour, 2010).

In the E-banking growth, security concern (Financial Service, 2001) and the quality of delivery service (Furst et al., 2000) were the major challenges.

Main advantages of Internet Banking are: increase productivity and efficiency, eliminate duplication and wastage, cut down maintenance and shortage cost, proper planning and monitoring and proper use of resources. From banks' point of view, the first benefits for the banks offering Internet Banking services is better branding and better responsiveness to the market.

2. Internet Banking in Romania

Currently, every third European uses online banking and there are no signs of a slowdown in adoption. By 2020, more than 60% of Europeans may use online banking (Meyer, 2010). Northern European countries are home of the most enthusiastic online bankers with adoption rates of 62-77%, followed by the European core with adoption rates between 35-54%, Southern and Eastern Europe that rates below 32%, and finally there is a group of countries (including Romania) where banking has barely taken hold (Deutsche Bank, 2010)

Romanian Internet Banking services market is in the early adoption stage; although developed rapidly over the last few years there are still considerable development opportunities. Most of these services were introduced in the years 2000 and 2001.

Table 1. Total value of Internet Banking transactions (mill. Euro) 2006-2010

Source: The Ministry of Communications, Technology and Information, Status summaries of the use of payment instruments with remote access form 2009 and 2010

The financial crisis had an enhancing effect on these services, and so we witnessed a positive trend concerning the number of users, the number of transactions conducted in Euro and the value of transactions.

Increased use of these services is due to the increase of Internet penetration among the population. According to a study published by ECLAC at the end of last year, Romania is among countries with the lowest degree of public access to Internet.

Table 2. The evolution of E-banking and Internet Banking users 2006-2010

Source: The Ministry of Communications, Technology and Information, Status summaries of the use of payment instruments with remote access form 2009 and 2010

The number of E-banking services users increased by 66% in 2009 compared to previous year, showing a constant interest and increased public awareness of such services, although according to a study of Deutsche Bank, less than half of Romanian small enterprises use E-banking and automated payment instructions.

The development is based primarily on the adoption and use of online banking applications by individuals. This expansion is not proportionally reflected in the increase of transaction numbers and their value, which indicates a lower use of these services compared with their extension.

An online survey conducted by Bursa de Reclama in 2010 shows that 31.1% of Internet users use E-banking. In general, banks with high market shares in offline have high market shares in online; the top four ranked in terms of number of users were BCR, ING Bank, BRD and Raiffeisen.

The potential of E-banking services has been identified by banks, which have as a challenge to provide online banking services easy to access and use, but also very safe. Not only do banks have realized the potential of these services, but also customers that have found an effective, economical and reliable way to manage their accounts and payments.

Table 3. Total number of Internet Banking transactions 2006-2010

Source: The Ministry of Communications, Technology and Information, Status summaries of the use of payment instruments with remote access form 2009 and 2010

The need to reduce costs has led banks to move a larger part of their operations towards alternative channels, which provide lower costs. On the other hand, customers are more aware of the price paid for bank services, the time spent, the speed and safety of operations.

E-banking services represent a challenge for banks' customers. In Romania, many will be persuaded to enter the race, and share with the bank the benefits of each online transaction.

3. Customers' perceptions on Internet Banking

The interview guide included 15 statements and respondents were asked to indicate their level of agreement with each statement. The main results of the survey:

- Convenience in Internet Banking constitutes the relative advantage of adopting the new service channel. Convenience in the form of time savings, 24/7 access, increased service efficiency

relative to branch banking and service quality was mentioned as the most beneficial features of Internet Banking.

- Of those who adopted Internet Banking, the major services used are bill payment, account transfer, account balance inquiry and interest rate/exchange rate inquiry.
- Consumers' concerns about security (reliability, safety and privacy), which arise from the use of an open public network, is the most important factor inhibiting the adoption and use of Internet Banking.
- Other key barriers to Internet Banking are: risk, other equally convenient channels of distribution and the lack of computer skills.
- A major part in convincing clients in using Internet Banking services is being held by the inclusion of demo applications on banking institutions sites, which stimulates the mode in which transactions are progressing.
- The main reasons for bank customers adopting Internet Banking were seen to be ability to perform banking transactions anywhere, anytime and quickly.
- The factors which contribute to users' intention to use Internet banking are: perceived usefulness, perceived ease of use and trust.
- Adoption of new technologies often comes across a certain amount of resistance to change from present ways of operating.
- Willingness to use Internet Banking depends on the expectations of accuracy, security, network speed, user-friendliness, user involvement, and convenience.
- The main benefits of e-banking were as follows: increased comfort and timesaving transactions made 24h a day, without requiring physical interaction with the bank; quick and continuous access to information as they checked on multiple accounts; better cash management.
- Private customers looked for slightly different kind of benefits from Internet Banking: reduced costs, speed, and fund's management.

- The Internet Banking design provides customers to see operation alternatives more easily.
- The bank branch is still the main connection way between banks and their clients, newer distribution channels being far from being well approached by clients.
- Internet Banking achieves high success rates through coordination with brick and mortar and bank branches in stores. Brick and mortar and Internet banking are supportive banking channels.
- Internet Banking, ATM, and phone banking substitute each other.
- Internet banking is one of the most reduced used of financial services.
- Internet banking operations depend on users' performance. So, ease of use and access are important characteristics of Internet Banking.
- The adoption of Internet Banking is dominated by male.
- The customers with most familiarity in using Internet Banking are the ones with the highest household income.
- Computer-literate Internet users are generally young and well educated.
- The study highlighted a strong association between age and the frequency of usage of e-banking services by customers with the people in the age group 31–45 years using most frequently. This is understandable as people in this age group are more tech savvy than the older generation and feel more comfortable in using and in doing business online.

The study clearly emphasizes the need for banks to understand that the financial products and services supplied over the Internet must not only be tailored to fulfill wants, preferences, security, and quality expectations of customers at the present time, but also be required to induce customers to demand and use e-banking on a wider scale in the future.

Expertise in marketing and the ability to anticipate changes in market conditions as well as in customer psyche are therefore crucial to the success of Internet e-retail banking.

4. Conclusions

Internet Banking is becoming one of the most important delivery channels of banking products. In response to global trends brought about by using the Internet, banks have to better understand their clients and respond quickly and strategically to market developments in customer centric ways.

The introduction of E-banking turned operations upside down and profoundly changed the overall logistics of the support system, to the extent that customers and competitors began to think differently about the bank's know how and mission.

Evidence indicates that there are a great promotional efforts on the part of banks to create greater awareness of Internet Banking and its benefits. It is crucial for a bank to think about the future of service.

Internet Banking future challenges are: Internet security, customers' trust, the speed of service delivery, customers' information privacy, customers' awareness, continuity of the service, spread of computer use, spread of Internet use, difficulty of using online banking by some customers, pricing of Internet service, Internet infrastructure, cost and difficulty of maintaining the site, and lack of legal regulations.

The adoption of Internet Banking provides added value for the customers and opportunities for banks to bolster income streams and secure longer term customer loyalty through relationship management.

Although Internet Banking offers new frontiers of opportunities, there are several critical psychological and behavioral issues that need to be addressed in trust, security, reluctance to change and a preference for human interface.

The development Internet Banking in Romania depends on: strategic factors (new products and services, appropriate promotion, business integration, integrating different channels, expanding existing markets, building trust, costs), operational factors (good customer services, simplifying and integrating basic services, understanding customer purchase behavior) and technical factors (systems security, user-friendly web interface, personalization and customization capabilities).

In order to survive, banks will need to move away from traditional bases of retail bank competition (fees, interest, customer loyalty), to a new Internet based form of competition based on cost reduction, customer retention, responsiveness, credibility, security, ease of use, and wider scope of products and services.

To exploit the high value end of the banking supply chain, banks will need to familiarize the consumer with the processes and benefits of the service and encourage usage.

Stress and Adaptive Mechanisms of the Seafarers

Rus Mihaela

„Ovidius” University of Constanța
psiholog_m@yahoo.com

Abstract

Today stress is psychological and not another time, mentally. This is especially multiforme and its mark where we least expect or not expect at all. Strain, race against time, pressure, but this is just the tip of the iceberg. No we have no idea of many stressors we have every day..

What happens then? What is this strange evil? Our working conditions are far from being so heavy like old times. Ever more sophisticated technologies are being developed to facilitate the tasks we most dirty and improve communication between us. Working time is reduced by regularly to leave more space to our private lives and leisure time.

And yet! All indicators show the danger. However paradoxical it might seem, occupational stress levels are unmatched, regardless of socio-professional category under consideration, employees or staff.

The consequences are difficult for the individual, whoever he may be: chronic fatigue, sleep disturbance, anxiety, depression, cardiovascular disease, digestive problems, etc.. For all these evils, one agent is responsible - stress, also in the Romanian landscape tragic news, we see cases of suicide in the workplace. Stress will be recognized as an occupational disease, as happens in other European countries.

Key words: stress, occupational disease, communication, organization

J.E.L. classification: L2, L25, L29

1. Introduction

Mental stress may be considered as a way of interacting individuals and the environment, reflected in a tense, loading. Iamandescu defines psychological stress as "a syndrome consisting of exacerbation,

beyond the mere homeostatic adjustment of certain reaction and their somatic corelator about external or internal excitation exerted by a configuration triggers (stress agents) that works hard, surprising, sudden and / or persistent and often having a symbolic effect, threatening, sometimes an extremely favorable for the subject

Some researchers distinguish among stress agents (foreign agent producing stress: noise, working conditions, lack of information or over subsolicitarea) those who threaten the psychological balance of individuals, causing intense stress (distress), which is the result of overloading and with direct impact on performance, attitude, behavior, subjective complaints and psychosomatic and / or endocrine reactions.

There is also a type of stress acting tonic, inclusive, with beneficial effects, positive empowerment of the individual resources - eustress, which keeps the tone of the man physically and mentally at a high level and has the effect of an adaptation, but stress negative-distress, defined as "stress that the potential harm to the body"

One thing is certain - a certain tension, the loading level of the organism is useful no matter what activity will take.

The minimum necessary impetus to action, mobilization of human energy as a stimulus is defined as shown, eustress. So moderate stress activates the body, it increases the adaptive capacity and only stress, to which adaptation is difficult or impossible, is harmful and should be removed.

2. Methodology of research

Professional stress and the study of its implications on professional satisfaction has been achieved on various occasions, it has been demonstrated concretely positive correlations ($p < 0.01$) effects and determinism that professional stress induces to professional satisfaction.

Fig. nr. 1 Professional stress and personal satisfaction

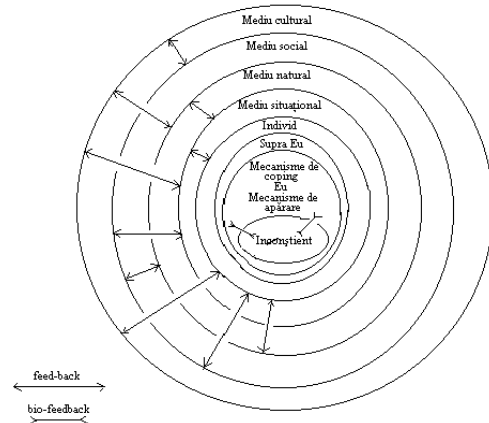

Of course, these efforts have highlighted the link between stress and satisfaction determination, finding that leaders must take account of organizations through strategies and transformational leadership styles of type in which performance is driven by job satisfaction and thus productivity in the workplace. Coping strategies used by the individual in his effort to adapt to disruptive factors are relatively elucidated but they are always mediated by individual and situational features, which make it difficult to develop general theories about their use by individuals.

Despite some criticism of the forms of integration defensive coping mechanisms, we can not ignore some evidence. There are clear results showing positive correlations rather specific situations, between denial and mental health. For example the percentage of survival and recovery from illness, was significantly higher in the cancer patients and those under open heart surgery which reacted with the same hopelessness of life circumstances. Instead denial proves to be counter-productive in the process of perception and interpretation of symptoms (Contrada, Liventhal and A Leavy, 1990). Avoiding proved effective in the short term, while confrontation proved to be a superior on long-term strategy (and Flecher Suls, 1985).

Research carried out on a group of subjects (N = 60), representing the crew has to analyze in a holistic manner, the mechanisms of adaptation of the human individual. Epistemological approach conducted along theoretical and practical

investigations to the realization of a general model for the positioning of the human individual in an existential universe, action that will help understand the environment action on individual.

Fig. nr.2 Action of environment on individual.

Creating a value axis and a positioning model of adaptation mechanisms, will lead us in a centered relational universe where the adaptive mechanisms multifactorial correlate and intercondition.

Fig. nr.3 Positioning model of the adapting mechanisms

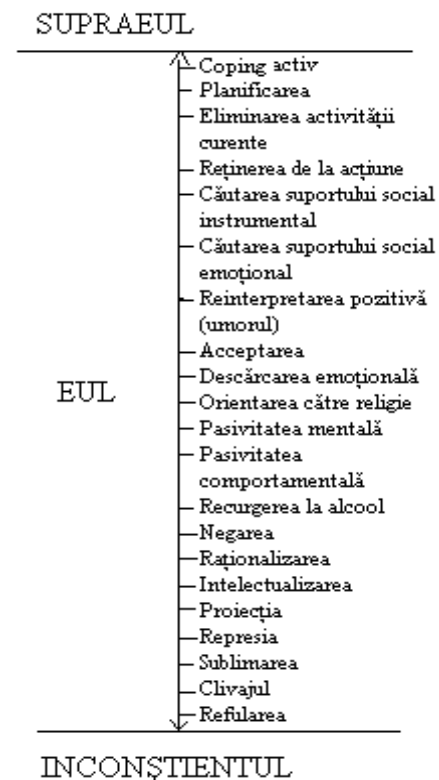

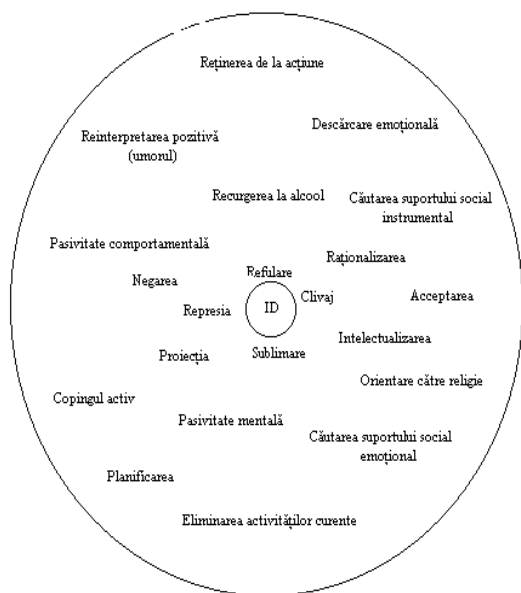

Fig. nr.4 Coping mechanisms

Imbalances caused by stress factors can lead to the use of adaptive strategies which in turn causes temporary disturbance in the worst case of permanent general homeostasis of the human individual. In the case of the research group made up of crew have emerged significant correlations between active coping and planning.

Table 1 Table of correlations between variables: active coping, planning

		COPINGUL ACTIV	PLANIFICAREA
Kendall's tau_b	COPINGUL ACTIV	1,000	,904**
	Correlation Coefficient		
	Sig. (2-tailed)	,	,000

	N	60	60
REINTERPRETAREA POZITIVA	PLANIFICAREA	,915**	1,000
	Correlation Coefficient		
	Sig. (2-tailed)	,000	,
	N	60	60

** Correlation is significant at the .01 level (2-tailed).

Defensive denial correlates significantly with the rationalization.

Table no. 3 Table of correlations between variables defensive denial and rationalization

		NEGARE DEFENSIVA	RATIONALIZAREA
Kendall's tau_b	NEGARE DEFENSIVA	1,000	,869**
	Correlation Coefficient		
	Sig. (2-tailed)	,	,000
	N	60	60
RATIONALIZAREA	NEGARE DEFENSIVA	,869**	1,000
	Correlation Coefficient		
	Sig. (2-tailed)	,000	,
	N	60	60

** Correlation is significant at the .01 level (2-tailed).

These correlations are understandable in view of strong autocratic environment where research was conducted, the two working instruments (SEMC and COPE questionnaire) used revealed links that can be raised to the rank of legitimate only if they can be validated by the results obtained with other tools being validated or in course of validation.

The ability to know what adaptive mechanisms used by individuals in certain stress conditions is an important step not to

be neglected in the selection of staff. Organizations must not only use this information to classify as the best available labor in the labor market, the jobs whose tasks may be performed with maximum efficiency and avoidance of serious events.

Cognitive Ergonomics highlights the improvement of the psychological profile of employment according to the particular individual, but certain jobs require a certain psychological profile that has to be closely superimposed over the psychological profile of the occupant position with specific processing capabilities and job availability at cognitive level.

Carry out research to highlight the correlation between adaptive strategies, personality factors and stress factors can bring to light and elucidate the adaptive mechanisms used by the subject in stressful situations and what implications have the personality factors in fighting stress (distress) so present in everyday life.

Protection Public Policies of Children whose Families are Temporary at Work Abroad

Rus Mihaela

„Ovidius” University of Constanța

psiholog_m@yahoo.com

Abstract

According to the development that the international migration has recently known in Romania and especially due to its manifest effects, there appear frequent questions related to the role the Romanian state played, is playing or could play in this migration. What the Romanian state did to control the process of migration, in order to offer support and protection to its citizens beyond the borders, what it did or not to limit any negative consequences and to maximize the positive ones (or in order to correctly assess them), there are issues offering topics for an actual debate. International migration, when we refer to millions of Romanians beyond the borders, cannot be neglected within migration policies [1].

Key words: migration, social policies, work, citizen, protection

J.E.L. classification.: I3, I31, I38

1. Introduction

Our preoccupation, in the first place, will be to identify the actions/measures that the Romanian government adopted from the migration control perspective, in relation with the evolution of the process itself. It is obvious the introduction of a dynamic dimension of measures. Our interest is not a general one, for the migration policies, but a specific one related to one of the most important form of Romanian migration: emigration for work (no matter its legal or illegal status). We are concerned only by these measures and institutions related to emigration for work in Romania and particularly these measures adopted within the outlets from Romania.

In recent debates concerning these topics, the government representatives but also those from the private sector admitted the need of a global market of an efficient work, taking into account that the perspectives concerning unbalances between labour demand and offer for the coming years indicate an increase in them, due to population aging and the population decline in developed countries, at the same time with its increase in developing countries.

At the same time, it is expected a perpetuation of disparities within the income level and the opportunities to find a job in developed and developing countries, generating new spheres for mobility and migration [2].

The OECD report in 2007 concerning international migration emphasises the fact that in 2005 the group of the most important source-countries remained relatively stable, having geographical proximity as a major determining factor in choosing the country in Europe but also outside Europe [3]. The origin countries for migrating towards OECD countries are characterized through a major diversity, the meaning and the intensity of the migration fluxes depending on geographical and linguistic proximity as well as on historical connections.

As far as the European Union is concerned in this respect, it proposes a large migration policy, offering an efficient and coherent way to answer challenges and opportunities related to migration. The enlarged approach refers to all the phases of the migration process and at the same time, applying efficient measures and policies concerning illegal migration and trafficking [4]. Moreover, it is also concerned with human rights and fundamental liberties of migrants, including access to actual procedures concerning asking for asylum request.

From this perspective, this study analyses the quantitative aspects of migration but also its qualitative ones, emphasising the challenges Romania has to pass through, resulting from its new status as an EU member.

As a consequence, migration is a complex process, with a multinational character that cannot be managed from one side or all around, but through an efficient management that should take into account the benefit of people involved but also the evolving features of the migration process. Within this context, the migration policies of the countries are modified according to world economy, political circumstances, the influence of different factors: natural or social. This section takes into discussion the policies and legislation concerning migration in EU and analyses the policies, legislation and institutions relating to migration process in Romania.

2. Policies and legislation in migration in European Union

Europe was and goes on being a geographical region with powerful migration fluxes in different directions, but it will represent mostly a destination area in future. In the past 30 years European policies in migration had a powerful restrictive nature, these changing after 1990 when it was tried a larger opening and a higher degree to accept immigrants in certain countries. Demographic decline associated with decline of qualifications at European level will determine a decrease of the future working population in Europe. Thus, it appears the necessity to find solutions to find to eliminate negative effects of demographic decline.

Thus, legal immigration is regarded as a way to counterbalance the decrease of the working population in Europe. Yet, it is considered that a controlled migration in the community space is more beneficial than leaving the migration policy at the discretion of each state member. As a consequence, there appeared a common immigration policy at community level, manifesting opening towards workforce from certain forces. A change of policy in migrating process within European Union is marked by Communication concerning Immigration,

Integration and Labour of the European Commission starting from June 2003.

At the same time, EU migration policies took into account four aspects to efficiently manage the migration process:

- policies to regulate and control migration fluxes

- policies to fight migration and illegal employment of foreign workers

- policies to integrate immigrants

- policies concerning international cooperation in migration field

These policies are reflected in the laws of European Union but also in the strategies and programs adopted in migration field. They took into account a coordinated approach of the migration issue, of the legal and illegal one, in the benefit of the European Union but also of the supplying countries.

3. Policies and legislation in migration field in Romania

Policies evolutions, legislation and institutions concerning migration in Romania have been strongly influenced by Romania accession to European Union, in the past years, respectively the need to ensure agreement with community legislation and the existence of an administrative institutional framework allowing the participation at EU policies in migration. Thus, there appeared a harmonization of the national legislation harmonization with community acquis in migration and there appeared measures to improve the institutional framework and the interinstitutional coordination to manage legal and illegal migration.

Legislatively, the existent national legislation was modified and completed, so that, at present it corresponds completely to the migration from European Union.

The present research proposes to emphasize the picture of the family affected by parents' migration abroad for work, with its main problems, measures taken by institutions involved in this very important social phenomenon, but not exactly scientifically known in Romania.

In realizing the scientific debate it had been taken into account the use of specific instruments for sociological instruments as well as the statistics data in giving the obtained results. The case study initially

started from a theoretical framework, essential in collecting data. The comparative spirit must cross the whole sociological debate to systematize, classify and clarify the data from the field data and from the library [5].

With the purpose of a better understanding of the research way, we crossed a series of criteria: temporal criteria, criteria regarding the investigational debate and also the macro-microsocial conceptual binomial. According to the temporal criterion, the rules and knowledge principles of social reality of the migration phenomenon enlist within the longitudinal analysis of the phenomena or social facts within their evolution through which the main method used was case study, the target of the study being children with parents left abroad from Constanta and Topalu village, in the city of Constantza.

According to the criterion regarding the investigative approach, the methodological approach of this research is one of intersection, where there is a combination between quantitative and qualitative approach. The starting point in the respective debate was the quantitative method in the following way: the working instrument used within this method was to emphasize the effects of parents' emigration and the measures taken in this respect, was the questionnaire. Within this qualitative method, one of the features specific to these methods is the fact they possess „more the function to understand than to systematically depict or to measure”, the keywords are „comprehension, profoundness” [6]. Personally, I was interested by the illustration of the changes produced in children by the migration phenomenon. The working instrument was the interview.

Another criterion was the conceptual binomial: macro-micro-social. Through analysing „macro” I took into consideration the migration phenomenon and its realities on the whole, and through analysing „micro” I took into consideration particularly the entities forming the phenomenon and the respective realities. We have tried to identify the social costs and the profound transformations in the child's life whose parents went to work abroad.

As a consequence, the research stages revealed the following:

- ✚ The achievement of a social inquiry relying upon the questionnaire of the group made up of students with ages between 10 and 19 years old from the School with classes I – VIII from Topalu village, the city of Constanța and Theoretical Highschool „Lucian Blaga” from Constanța.
- ✚ The achievement of interviews with professionals from didactic field within school and highschool
- ✚ The achievement of interviews with specialists from medical, psychological and social care field from the community.
- ✚ Analysis and presentation of the statistical results.
- ✚ Presentation of the social care in Romania and the case management made by social care workers for children in difficulties due to their parents' leaving abroad through exhibiting the case study of a child with problems caused by this phenomenon.

The objectives of the research were to identify the following aspects:

- ✚ The image of the family affected by external migration phenomenon.
- ✚ The reasons for the decision to go to work abroad.
- ✚ The way children are affected by the lack of one or both parents.
- ✚ The quality of the relation child-tutor
- ✚ Measures adopted by school authority for children with their parents left to work abroad.
- ✚ Measures adopted by authorities through institutions and services for children affected by parents' emigration.
- ✚ Presentation of a case of a child whose mother left to work abroad and how the institutions managed to help him in collaboration with child protection institution.

The collection of the data was done as it follows:

- ✚ Identifying children with parents left for work abroad from the school units mentioned above.

I realized a questionnaire involving 15 questions and it was applied to a number of 80 children: 60 children from the urban area and 20 children from the rural areas(see diagram 1).

Figure no. 1: Diagram for variable social background

I have realized an interview guide with 5 questions, applied to a number of 20 professionals from didactic, medical, psychological and social care field: 15 teachers, 2 doctors, 1 psychologist and two social care workers from the city of Constantza but also from Topalu village.

Social-demographic features of the family: family-child profile

In order to realize the family profile, the framework profile that we tried to identify were: which parent leaves the family and opts to go to work abroad, the duration of the leaving, the reasons for this leaving and their importance, the effects felt by the remaining family (positive and negative aspects); grouping them in four presentation fields: social-demographic features, relation child-tutor, determining factors, consequences upon the family and measures taken by the specialists that come into contact with these children.

Figure no. 2: Diagram for specialists taking part at the interview.

Social-demographic features

At first question from the questionnaire „Do you have relatives abroad?“, the whole group of subjects answered affirmatively as a consequence of the purpose of this questionnaire to be applied only to children with parents at work abroad. Thus, in most situations, parents who decided to go to work abroad had already relatives or acquaintances in the emigration country (in rural areas, 5 assert that besides family members, they also have relatives and acquaintances, meaning 25% and in urban area, a number of 22, meaning 37%) and only a small part of these have neighbours or relatives left in the respective area (in rural areas, 2 persons asserted they had friends, meaning 10% and only 3 that have neighbours besides family members, meaning 15%, and in urban area, 8 meaning 13%, respectively 5, meaning 8%). This could be explained by the fact that parents usually benefit of the help of migration contacts, which help them and support them by anterior migrants represented by relatives, neighbours or friends.

Figure no. 3: Diagram concerning the number of relatives and other acquaintances left abroad

In most situations, the parent opting to leave the country for work is the mother in rural area, in a proportion of 50%, father in 35% and both parents in 15%, and in urban area, the parent opting to leave the country for work is the father in 48% cases, mother in 24% cases and both the parents in 28%. (see Figure no. 5). We can notice that in rural

areas the missing parent in a family is the mother while in urban areas is the father. And still in the urban areas there is more frequent the case when both parents leave for work abroad.

Figure no.4: Structured diagram with parents left abroad for work

Although mother's presence is determining to a normal development for a child, most of the times she is not present within the family on a period of less than 3 months in rural areas, in urban areas she misses between 3-6 months, thus the mother's absence in the family from rural areas is shorter so that it may not affect the child too much. In urban areas, mother missing between 3-6 months, the effects are more serious like: school problems, behaviour problems, communication within the family and in friends' group.

Figure no.5: Diagram concerning the period parents left for work abroad

Most parents miss between 3-6 months in urban areas, and 6months-1 year in rural areas, a significant number being represented by fathers in urban areas and mother in rural areas. When the parents miss a longer period

of time, children cope with the situation hard, the effects upon their development and their growth being numerous and more emphasized.

The longer they stay in a country, the greater the possibility of parents to remain separated from their family.

At the question how often children communicate with their parents left abroad for work, most asserted that quite often.

Figure no. 6: Diagram concerning the keeping in contact of parents left abroad to work with their children

There can be seen the difference between rural areas and urban ones as far as the frequency of communication between children and parents is concerned thus, children from urban areas communicate really often with their parents in comparison with rural areas where children communicate really seldom with their parents

The number of both parents going abroad for work is significant (28% in urban area but also 15% in rural area), most parents missing from their family longer than 2 years (11%), entrusting their children to their grandparents (65% in urban area, respectively 67% in rural ones) rather than to their aunts /uncles (18% in urban area). Yet, there are serious cases when children remain by themselves, a part of their parents' responsibilities being taken by elder brothers and sisters (29% in urban area) or by themselves (33% in rural areas). The absence of parents in children's lives at tender age affect the way they commit to other persons, their sense of safety and self-esteem, as well as their future development as fully-grown adults.

There are situations when parents decide not to entrust children to other adult person, the children remaining by themselves, the responsibility in the house belonging to an elder sister or brother.

No matter what parent goes to work abroad, children remaining at home are usually girls, something that can be correlated with the feminine side of the investigated individuals (61%), with age between 12-18 in most cases.

Families affected by this phenomenon are young families, with major work resources, with age between 25-45 (86%). Young parents leaving abroad equal the workforce demand on the external market oriented on this category of individuals.

Figure no. 7: Diagram structured according to the parents' age.

According to the family structure there can be traced another feature. Most parents deciding to emigrate come from legal families (86%), most of them having 2, 3 children going already to school.

Figure no. 8: Diagram structured according to the family type from where children with emigrant parents are part of.

A feature of these families is related to the age of inquired children. Most of them being included in the age category 12-15 years and 17-18 years mostly representing students from 4th, 6th, 8th in rural areas and 8th, 11th and 12th in urban areas. There can be a correlation between parents' leaving and the child's sex. The option to migrate abroad is more frequent among families with daughters, students in highschools (71%) than in those with boys attending the same studies (29%). Parents tend to trust more the girls, who seem to be more responsible in problems concerning the household.

Figure no. 9: Diagram concerning the child's sex according to their social background.

Another feature of the family directly affected by emigration is the number of their children. In rural area, the option to migrate is more often encountered in families with 3 children (50%), following in decreasing order families with two children (30%), with one single child (15%) and those with 4 children (5%), and in urban area unlike the rural area,

the option to migrate appears more often in families with 2 children (35%), following the families with one single (31%), 3 children (22%) and those with 4 children (12%).

Figure no. 10: Diagram structured according to the number of brothers of the respective child.

As long as the correlation with children's classification, most of them are first born of the family (59% of all children participating at the study), something that can be correlated with an increase of responsibility among them.

There comes in decreasing order the values in percentages from the second child born in the family up to the fourth born within the same family.

Figure no. 11: Diagram concerning the classification of children involved according to their place in the family.

Regarding the job parents have in the emigration countries, men usually work in the following fields: navigation, construction, electricity and carpentry, and mothers usually work as: maid, baby-sitter, salesman. At the measurement time, a considerable number of those left abroad for a short period of time (0 – 3 months and 3 – 6 months) did not have a job, something that can be associated with the absence of the positive

effects, that could be noticed within their families.

If the left parent has the mission to find a job and to financially support the family, the remaining at home parent is not at work, dealing with children raise and education.

4. Conclusions

Migration is a complex phenomenon with a multitude of effects. The phenomenon has important consequences in society economically, socially, culturally and politically.

In European Union, legal migration could represent a favourable factor for economic growth, when correctly managed and oriented towards deficient sectors. Yet, member states perceive differently this phenomenon, according to the specific context. Moreover, the public perceives migration in a negative way, especially that from certain countries. The policies concerning development should include corresponding measurements to efficiently manage the migration phenomenon. This appears in the conditions of an aging of population from European Union, with important consequences on the labour market but also upon the health and retirement systems. The connection between demographic changes and policies concerning migration is and will continue to be an important issue of European Union in the near future.

The economies and the member states societies will go on needing migrant workers. That is why, it is necessary a common approach of the dynamics of management migration and harmonizing policies concerning migration of the member states.

If until 2007 the prior preoccupations oriented upon legislative and institutional harmonization in order to achieve community acquis, after EU accession. Out of this perspective we completely share the perspective expressed by the National strategy concerning Immigration within 2007-2010 according to which: "migration is a process that must be managed and not a problem that has to be solved"

At present Romania has a good system of strategies, policies, measures plan to administrate the migration phenomenon, but the greatest challenge appears when they

have to be transposed in practice. In this direction, there must be ensured a modern, competitive management, ensuring the best utilization of human resources and materials used with this purpose.

Legislatively, Romania completely transposes the community acquis in the migration field. There must be taken into account that have present migration policies changes at European level with the tendency towards a greater opening to attract labour force from certain countries. These political changes attract new directions of the requests that must be nationally transposed. Romanian will have to continue the permanent alignment to European policies and legislation within migration, that at present knows a stronger dynamics.

In Romania, there is a complex, strong framework, but also fragmented, leading to deficiencies in communication between institutions responsible with migration or even between departments from the same institutions, that have different competencies within migration field. This way, there appears the necessity of a better intra and inter- institution cooperation, coordination and information to manage the migration process. The integrated informational system is of great utility, a system where all institutions should participate with information and should be accessible to all involved institutions and departments.

Often institutional changes through reorganizations, foundations and dissolutions of institutions and directions within institutions leading to a major fluctuation of the employed, so that in most cases, it is lost the possibility to occupy certain positions with consequences upon the continuity of the respective activity.

In the actual European context related to migration and to problems that Romanian workers have to face, Romania should express its position more loudly and advocate for changing the perspective upon work migration and mobility: they represent two interdependent concepts, that should not depict distinct realities like mobility of citizens from the older member states versus migration of the citizens from the new member states.

Abstract

Costing management represents an information and a management tool used in order to improve enterprise performance.

This provides information on cost, profit, but can also be a technique to "maximize profitability" (management tool).

The information produced by costing management extends from the productive level to the commercial level, allowing managers to evaluate strategic business alternatives, in order to choose the optimal variant of development. That expending supposes complying with some procedural techniques.

Key words: management accounting, direct costs, indirect costs.

J.E.L. classification: M41

Costing management represents an information and a management tool used in order to improve enterprise performance.

This provides information on cost, profit, but can also be a technique to "maximize profitability" (management tool).

The information produced by costing management extends from the productive level to the commercial level, allowing managers to evaluate strategic business alternatives, in order to choose the optimal variant of development. That expending supposes complying with some procedural techniques.

Business expenses are all expenses incurred by a unit that is specialized in trade activity and may relate to "wholesale", "retail", catering, foreign trade, etc.

Classification of trade costs can be made according to different criteria:

- Economic nature;
- The activities that generates them.

Classification by economic nature is the foundation of organization and leading of financial accounting in all fields.

By the activities that generate them, trade costs can be classified:

- Direct costs, identified per unit and group of products;
- Indirect costs, identified per unit;
- Double indirect costs, identified per company (general and administrative expenses).

There are cases of companies (SMEs) in which the management and administration function is not separated from commercial function, for which it uses to monitor and control trade spending, account 925 "business expenses" that grow in accounts Grade II operational.

Customize adaptation of management accounts to trade activity; starting from the general framework can be depicted as in Table 1.

Organization of management accounting in a commercial activity: study of a subsidiary).

A. The general framework of the wholesale business in case of X branch

In order to conduct business, specializing in wholesale units must have commodity stocks.

Inventories of goods, in accounting, are fulfilling a dual role:

- are the primary heritage element;
- are factor for calculating the cost of procurement of goods sold.

In terms of the reporting period, is met:

- initial stock of goods (from the beginning of the period);
- final stock of goods (from the end of the reporting period).

Table 1. Management accounts in trade activity

Account	General framework	Correspondence	Account symbol	Adaptation to the commercial activity groups and accounts
90	Internal settlements	↔	90	Internal settlements
901	Internal settlements regarding expenses	↔	901	
902	Internal settlements regarding production	↔	902	
903	Internal settlements regarding price differences	↔	903	
92	Calculation accounts	↔	92	Calculation accounts
921	Main activity costs	↔	-	
922	Auxiliary activity costs	↔	-	
923	Indirect costs	↔	923	Indirect expenses of operating units
924	General administrative expenses	↔	924	General administrative expenses
925	Sales expenses	↔	925	Commercial expenses
93	Production costs	↔	93	Revenue from trading activities
931	Obtained production costs	↔	931	Revenue from trading activities
933	Cost of production in progress	↔	-	

Source: personal processed data

To determine the cost of supply of goods sold, will add to the cost of purchasing the initial stock, the value of goods acquired during the acquisition cost, after which they will deduct the final stock of goods valued at acquisition cost.

In wholesale, is used the purchase price (invoice price of the units producing goods to wholesale trade establishments) and the selling price (charged by commercial establishments, wholesale sale of goods by retail trade enterprises, i.e. price buy + trade margins).

Steps on the movement of wholesale goods in the case studied are shown in Figure 1.

According to the steps shown in Figure 1., the goods movement in a society realizes through 2 storages.

The steps of the goods movement are:

1. expedition of the goods by the supplier to the branch, based on the invoice and other documents accompanying the goods;
2. the goods transportation, conducted by either the manufacturer or the customer or a third person;
3. goods reception, in order to register them in accounting

4. goods transfer to the second storage.

The organization of management accounting so that they could pursue economic and financial analytical results on each deposit in hand, will be properly spelled by Analytics accounts management:

902 Internal Settlement of commercial activities

903 Settlement on the results of internal Commercial

925 business expenses

931 Revenue from trading activities

In this case, the records will take stock of goods through the flash inventory in management accounting, in purchase price, with the help of account 9471 "Goods", which will be detailed in the analytics for the two warehouses and two categories of goods (parts and agricultural machinery).

From the above, it is necessary a developed variant of management accounts, which aims to: highlight the analytical inventory, costing and results calculation by cost carriers.

In developed variant appears group "94" - "Accounts for inventory" for evidence and analytical management of stocks, group "97" - "incorporation differences" for defining the differences not captured, and group "98" - "analytical results" for calculating and recording the analytical results.

B. Operations of the reporting period

The economical and financial operations were carried through the two accounting circuits (financial and management). Putting data from financial accounting to management accounting was done through logging and conversion array of economic

and financial operations using the "log record" (for each accounting) which may be single or double, the operations being logged in the two circuits simultaneously. To reduce the workload, the "Double-Journal" was used.

Abstract

In practice and in economic theory is increasingly accepted the belief that the masters of costs have the biggest opportunities to win the global competition for supremacy. In essence, the progress of any kind should determine the achievement of economic goods with the lowest costs. The basic concept of direct-costing method is the foundation product cost calculation using only variable costs. Attribution of indirect variable costs be made generally without difficulty because the variable costs are, by definition, normally related to the production and sale.

Key words: direct-costing, costs management, variable costs, management accounting.

J.E.L. classification: M41

In practice and in economic theory is increasingly accepted the belief that the masters of costs have the biggest opportunities to win the global competition for supremacy. In essence, the progress of any kind should determine the achievement of economic goods with the lowest costs.

Costing method include a set of processes which "provides quantification of the correlation between costs and production that occasioned them.

Direct-costing method is a step in the evolution of calculation, and in accounting, a management tool.

The basic concept of direct-costing method is the foundation product cost calculation using only variable costs. Therefore, the French authors refer to this method as a *variable cost approach*. French general accounting plan, in 1982 uses the

name: *proportional costs method*, and some authors identifies direct-costing with the *marginal cost calculation method*.

Fixed costs are constant, the distribution per products is considered at the end of the period and it is affecting business results. These two categories of costs give decision makers a clearer picture of how the production process is running.

Attribution of indirect variable costs is made generally without difficulty because the variable costs are, by definition, normally related to the production and sale.

The category of variable costs for varying physical volume of goods or dissolution, are, in addition to direct costs (materials, labor, steam, electricity for technological purposes, expenses of selling variable nature etc..), and indirect costs variables (heating fuels, contributions to social security, etc..), where variable costs cannot occur only under conditions of productive activity.

In view of direct-costing method, the concept of variability of production costs covers all costs, regardless of their mode of employment (directly or indirectly) on products. A feature of variable costs is the ease and accuracy of their distribution per unit of product and their permanent control by each leader upon his level of responsibility. In contrast, total fixed costs have a relatively constant compared to the change in volume of production and distribution of products and places them on costs cannot be performed using conventional methods of distribution.

The basic problem of the direct-costing method is the proper segregation of the variable costs to ensure a fair fixed production cost calculations.

Elimination of fixed cost calculation is based on the recital as expenses in the period are not the products. For this reason, they

cannot be included in cost of products, affecting the outcome of the activity.

Costing in the design of direct-costing method based on the elements of the production output, the volume of production sold in a period of time. Subtracting from the value of sales variable costs for the products sold, obtain coverage or gross margin contribution (limit gross, gross profit) to cover the fixed costs of the period.

The study was made on a company that has the activity profile marketing and maintenance of IT equipment.

The company sells products and services on a contract basis and / or order so used

direct-costing method of calculation. The object is the calculation of the order / contract.

Cost control is calculated after its completion, regardless of the length of time it runs, through the ratio of production costs by the number of products / services sold.

During month X, the company received three orders: Product1, Product 2 and Product3, for which are used some codification: C1 for product 1, C2 for product 2 and C3 for product 3.

Operating expenses incurred for the production of products are (table 1):

Table 1. Operating expenses

No.	Expenses	Total	Variable			Fixed
			C1	C2	C3	
1	Supply expenses	8794.48	3838.84	3392.80	1562.84	
2	Auxiliary materials expenses	1413.49	600.50	514.39	298.60	
3	Fuel expenses	943.09	349.05	259.04	250.00	85.00
4	Spares expenses	141.53				141.53
5	Non-storable materials expenses	640.00	154.30	210.00	90.00	185.70
6	Expenses on energy and water	2957.00	915.00	360.00	375.00	1307.00
8	Staff remuneration expenses	7652.93	2773.66	2510.80	769.47	1599.00
9	Salary related expenses	3654.26	1324.42	2523.33	367.41	1130.93
10	Maintenance and repair expenses	2685.00				2685.00
11	Banking and similar services expenses	395.09				395.09
12	Other operating expenses	1449.30	215.00	234.85	85.00	914.45
13	Operating expenses for depreciation	1298.54				1298.54
TOTAL		32024.71	10170.77	8680.79	3798.32	9374.83

Source: personal processed data

During the reporting period were obtained:

of the C1 product: 9 pieces from a unitary variable costs 1130.09 lei-

the product C2: 22 pieces to a unit variable cost 377.43 lei

product of C3: 25 pieces to a unit variable cost 151.93 lei.

During the same period were sold :

of the C1 product: 9 pieces for sale at a unit price of 1500.00 lei

the product C2: 23 pieces for sale at a unit price of 600.00 lei

product of C3: 25 pieces for sale at a unit price of 300.00 lei.

At the end there is no production unfinished / unsold.

According to direct-costing method can be determined specific indicators, each product being judged by its contribution to non-distributed costs (cost structure, fixed). This treatment allows reasoning on the opportunity of suppressing or developing sales of a product.

Table 2. Indicators calculated through direct-costing method

PRODUCT	Observations	C1	C2	C3	Total
Produced Quantity (q)		9.00	23.00	25.00	
Variable cost per product ($cvu=cv/q$)		1130.09	377.43	151.93

Variable costs per sold production	(according to BI analysis)	8409.24	9064.30	5176.75	22650.29
Unit sale price		1500.00	600.00	300.00	
Sales value		13500.00	13800.00	7500.00	
Gross margin per unit ($mu=pv-cu$)		369.91	222.57	148.07	
Gross margin ($mu=pv-cu$)		565.64	205.90	92.93	
Share of total gross margin in total gross margin production	100.00%	27.40%	42.13%	30.47%	
Share of total gross margin in total gross margin production	(100% according to BI analysis)	41.90%	38.98%	19.12%	
r = margin rate of variable costs =		0.25	0.37	0.49	
r= margin rate of variable costs (according to BI analysis)		0.38	0.34	0.31	
r' = rate of variable costs =		0.75	0.63	0.51	
r'= rate of variable costs (according to BI analysis)		0.62	0.66	0.69	
Prove $r+r'=1$		1.00	1.00	1.00	

CA=total sales figure=	34800.00
CV=total cost of sold items=	22649.95
M=total gross margin=CA-CV=	12150.05
r =margin rate of variable costs=	0.35
r' =rate of variable costs=	0.65
Prove: $r+r'=1$	1
CF=fixed costs	9374.83
R=result=M-CF=	2775.22

Source: personal processed data

Calculation scheme used is:

Table 3. Calculation scheme

No.	Indicators	Calculation	Value
1	Sales figure	X	34800.00
2	Variable costs	X	22649.95
3	Rate of variable costs	1-2	12150.05
4	Fixed costs	X	9374.83
5	Result	3-4	2775.22

Source: personal processed data

The data presented shows that all the margins on variable costs of the products studied are positive and therefore, all products contribute to cover fixed costs.

Structural Adjustment of Romanian Foreign Trade after EU Accession

Rusu Nicoleta

„Alexandru Ioan Cuza” University of Iasi,
Faculty of Economics and Business Administration
nicol_2182@yahoo.com

Abstract

As the diversification the structure of economies has boosted economic relations between the countries which had a decisive influence on the economy and structure of branches, which had constantly adapted to market requirements and resource supply options. Therefore, Romania's foreign trade, one of the most important structures of the Romanian economy has suffered a series of changes designed to improve its competitiveness through an inter and intra-industry restructuring. Once Romania joined the European Union have been produced a series of changes in the structure of foreign trade. However, Romania remains a net importer this failure resulted in restructuring the economy, which further led to record a deficit in balance of payments current.

Key words: foreign trade, FDI, exports, imports, trade deficit.

J.E.L. classification:F13, F14, P33, Q56

1. Introduction

After completing the period of transition from centralized economy to a market economy, and after accession to the European Union, Romania faces a new and difficult challenges of adapting the existing to European economic structures and legislation. It has to cope with changes both in economic and trade policies and external shocks due to economic crises and the effects of globalization. The accession of the European Union has meant for Romania a pressure on the state sector and the private sector, the exporters to adapt to unique market requirements. Recently have shown significant changes in our country's trade

structure, due mainly of macroeconomic, which required all commercial operating continuously adapt to changes in the commercial sphere.

2. The trade policy

Starting with integration into the European Union have been produced important changes in trade policy and practice of Romania. Thus, Romania has had to align all its policies, including trade policy to the European Union [1]. The main changes were:

- The adoption by Romania of the Common Customs Tariff;
- Liberalization of trade in the European Union;
- Romania's transformation from GSP beneficiary countries of the donor of preferences;
- Cancellation of the free trade regime between Romania and Moldova;
- Romania's participation in preferential trade agreements and EU non-preferential.

The importance of trade policy derives from the role of international trade as the main tool of connection of the national economy and international economic environment [2]. Thus, foreign trade plays a major role in providing the economy with raw materials, efficient use of labor-intensive capacity production, technology transfer, building a national competitiveness.

3. The dynamics of foreign trade of Romania after EU accession

Romania's foreign trade since the transition period was characterized by an orientation of its main markets of the European Union on the one hand, and on the other hand by a widening balance of payments deficit. Currently, although the majority of exports were directed mainly on European Union markets are observed according to the studies of the Ministry of Economy, Trade and Business has a tendency to shift exports to third countries, they account for 28,5% holding in total trade in January 2011 to 27,8% in 2010. This trend can be explained by the one of the objectives of the National Export Strategy, provides greater export orientation towards non-EU countries.

It should also be taken into account foreign direct investment, which is an essential component in the external trade performance, contributing significantly to finance current account deficits, which it has an important role in supporting a sustainable economic expansion, especially if they are directed to tradable goods sector. Investment has played an important role in restructuring the Romanian economy, contributing to technology transfer and in the same time a trending effect, which is stimulating a domestic competition.

Since 2003, direct foreign investment registered an upward trend, Romania attracted in 2008 investments worth 9496 billion euro, placing Romania into an attractive destination in this regard. In 2009 they recorded a sudden drop by about 50% leading to an uncertain economic situation in our country.

As I said above, this period is characterized by an intensification of trade relations, therefore the developments in international trade is recorded upward trend. During this period, trade policy has been to restructure the geographical diversification of trade and industry by industry sector for goods and services. Thus, while trade flows have been directed by the highest proportion in the EU markets, there is an increase, although small-scale non-EU trade flows to markets. This trend is a result of trade policy liberalization of trade in goods and services

markets of the European Union.

However, Romania is a net importing country, the share of imports is still much higher volume of exports, this having a negative impact on the current account balance. Liberalization policies have favored the inflow of foreign trade goods, raw materials from abroad, while the export value although it had an upward trend, it was not sufficient [3].

Fig.1 Exports (FOB), imports (CIF) and the balance of FOB/CIF foreign trade operation 2007-2010

Source: National Statistical Institute – data processed by international trade bulletin (2007-2010)

As we see in the picture above, the balance of exports/imports is negative; it's reflecting the economy's ability to conduct international trade.

Among, many causes that led to this note: [4]

- Disparity of markets at the start transition period that;
- Correlation of trade liberalization policies of our country's foreign economic restructuring measures, including raising the quality of products;
- Low tech;
- The use of excessive interest on loans to entrepreneurs, especially for export production;
- Lack of a coherent industrial policy, based on resources;
- Investment policy to attract direct train insufficient.

Although Romania has registered an upward trend in recent years to attract FDI, but they have not been sufficient to covers the deficit created by the imports.

International experience shows that there are countries that are net exporters and net importing countries, but the latter, the deficit has been covered by foreign loans created.

If the investment policies are correct, the income derived there from, covering the trade deficit. If these loans are geared towards consumption, as Romania case, the created deficit deepens and it became difficult to fill. Although exports increased, for example in Romania has exported goods worth 37,3 billion euro, 8,2 billion more than in 2009. According to Eurostat, Romania recorded in 2010 a trade deficit of 9,5 billion, it fell to 400 million euro the previous year. National Commission estimated that the deficit forecast by Romania, in 2008 and 2009, to reach 10,2% of GDP, followed in 2010 to record a decrease to up to 9,7% of GDP.

If we analyze the data 2007 - 2010, noted that the first two years, there has been a growth in exports by 13%, and since 2009, amid the global crisis, there was a substantial reduction of their.

Fig.2 Structure of exports FOB by main groups of goods 2007 – 2010 %

Source: National Statistical Institute – data processed by international trade bulletin

A comparative analysis of the structure of exports to production stages indicates an expansion in the share of exports of capital goods and materials along with a reduction in the intermediate goods and consumer goods.

According to the National Export Strategy 2010-2014, over the 60% of the value of increased exports resulting from a larger volume of exports, materialized in the export of machinery and electrical machinery, grain, automobiles, tractors, petroleum products, pharmaceuticals, seeds, fruits, boilers, turbines, engines, equipment and mechanical devices, and on the other hand, the remaining 40% representing the contribution of higher external prices (iron products, steel, petroleum, rubber and articles there of rubber, furniture and lighting).

The largest share in Romania's exports were manufactured goods, 94,8% in 2008, registering an increase of 11,7 percent over the previous year. Increases in exports were registered for radio equipment, television and communications, information technology and office equipment, tools, medical equipment, rubber and plastic products, transport vehicles, machinery and equipment [5].

Lately there has been a growing trend in the share of IT&C services in Romanian exports. IT&C industry share in GDP remains relatively low in comparison with other European countries (in which the range of growth was between 5% and 10%) and had a negative growth after 2005. According to the studies conducted by Eurostat, the exports of the IT&C sector, in 2009, increased by 10% over the previous year.

By category of service, according to National Export Strategy 2010-2014, the period from 2002 to 2008 was characterized by a remarkable growth in services, while increasing tourism and travel services.

As for exports, the EU market remained the main supplier of imported products, they totaled in 2010 a rate of 72,8% of total imports. The main groups of imported goods remain machinery and mechanical devices, followed by chemicals and plastics.

Fig.3 Structure of imports CIF by main groups of goods 2007 – 2010 %

Source: National Statistical Institute – data processed by international trade bulletin

According to the dates published by the Romanian Trade Promotion Center and Foreign Investment, the main structural changes occurred in the evolution of the combined nomenclature section of a growth trend in 2010 compared to the 2009, in the automobile industry products (including electrical, electronic) + 7,7%, this percentage increase was 73,6 million, chemical products and plastic products (+7,5%). A downward trend in food products have been -45,7 million euro (-15,8%), wood and paper products industry (including furniture) (-11,7%), textile and leather products industry (-4,8%) and articles of stone, plaster, cement, glass and ceramics (-18.8%) [6].

According to the Ministry of Economy, Trade and Business, the import volume in 2010 was 46,71 billion euro, an increase of only 19,9% compared to 2009, this mainly being due to continuing investment in productive activity reduction of consumption in Romania.

4. Geographical distribution of foreign trade

Romania's foreign trade is conducted in most European Union countries in 2010 with a share of 72,7% to 72,8% in exports and imports. According to the reports made by the Ministry of Economy, Trade and Business exist an increasing trend in exports

to third countries which are less affected by the crisis (38,7% increase in exports, well above the average of values in European Union 24,4%). Among countries with significant increases include: Japan – 74,73% increase in exports (car parts, bearings, electrical products, glassware, wine, etc.), South Korea – 49,37% increase (energy industrial equipment, maritime and river ships, fertilizers and animal feed), China – 45,15% increase (car accessories, fertilizers, power equipment, tires and rubber products, wines), Canada - 3-fold increase in exports (32,1%) (electrical machinery, boilers and nuclear equipment, components and parts for airplanes), USA – increasing by over 61% (auto parts, fertilizers), Mexico – increasing by over 51% (tires, carpets, various steel products, optical instruments, car accessories), Russian Federation – 62,12% increase (car parts, refrigerators and furniture), Ukraine exports growth of 53% (mineral products, machinery and electrical equipment, automobiles and auto parts), Turkey increase of 76,8% (mineral products, chemical products, metal products, machinery and electrical appliances, automobiles and auto parts etc.)[7].

More than 50% increase in exports was registered by Armenia (510,91%), Azerbaijan(112,59%), Kazakhstan (66,86%), South Africa (99,49%), Libya (50,11%), Republic Vietnam(74,82%), Brazil (61,61%) According to the dates from the National Bank of Romania, in 2010, top 10 countries of destination for Romanian exports were: Germany (with a share of total exports of Romania to 18,2%), Italy (15,2%), France (September 2%), Hungary (5,7%), Turkey(5,2%), United Kingdom (3,6%), Bulgaria (3,5%), Spain (3,4%), Netherlands (2,9%) and Poland (2,6%), cumulative weight of these countries being 69,5% in total of export. On import the first 10 countries of Romania (countries of origin for imports) have a share of 69,4% of total of imports realized in 2010, namely: Germany 17,0% Italy 11,2%, Hungary 7,6% France 6,2% Russian Federation 5,8%, China 5,7%, Austria 4,5%, Poland 4,1%, Netherlands 3,9% and Turkey 3,4%. Romania's trade deficit on the Europe was 320.9 million euro. According to studies conducted by National Bank of participating countries to achieve the deficit were: -119.0 million euro Russian

Federation, Kazakhstan -81,2 million euro, Hungary -76,1 million euro, Austria -65,5 million euro, Poland and Germany -51,6 million euro, -46,7 million. Asia-Oceania, the trade balance was -210,3 million euro (with the highest levels of trade deficit on relationships: China -136,2 million euro, India -22.6).

Fig. 4 Geographical orientation of exports in 2010

Fig. 5 Geographical orientation of imports in 2010

Source: Romanian Center for Promotion of Foreign Trade and Investment – data processed by Romania International Trade

The main exporters to the EU market were Automobile-Dacia, Nokia Romania, Honeywell Technologies, and third country markets, ArcelorMittal Galati, Rompetrol, Nokia Romania, Renault Industrie.

5. Conclusions

Romania's foreign trade, despite its correlation with GDP, largely depends on economic activity, only the structure of imports is affected by industrial production. However, considering the situation of foreign trade since joining the European Union so far have shown a significant change in the business, primarily due to macroeconomic and secondly, opening up EU markets for Romania.

The negative balance between the exports and the imports, reflect a high level of inefficiency in economic activity, the deficit gradually altering the balance of the trade. These negative aspects are related to lack a solid investment policy could cover the deficit created.

Although significantly reoriented, Romania's foreign trade continues to be unstable, poorly restructured, and less competitive.

FDI is a major determinant of improvement in foreign trade. Although Romania has registered an upward trend in recent years in attracting FDI, it should work harder to attract investors, by policies of reducing taxes and bureaucracy, improve infrastructure, the national law is not sufficient for an improvement in foreign trade activities.

Business Ethics from the Perspective of the Students in Business and Economics – Identifying the Factors of Variation

Rusu Sabina Mihaela

"Alexandru Ioan Cuza" University of Iasi, Doctoral School of Economics

mhl_sbn@yahoo.com

Abstract

The paper attempts to explore the theme of business ethics from the perspective of the students in business and economics as future business practitioners.

The ethical business principles are considered to be formed before an individual enters into the work market and as a consequence it is assumed that the educational system can be responsible for this situation. Still, it is unrealistic to expect that students with the same ethical course exposure will adhere to the same ethical conduct. The purpose of this paper is to measure the ethical standards of a group of students and to identify the factors that determine the variation in their responses.

Key words: business ethics, ethic courses, student's ethics

J.E.L. classification: M29

1. Introduction

The notion of ethics is related to the notion of moral or morality and it is based on the idea of custom as normal behavior [5]. But an ethical issue, rather than requiring the appliance of a norm, is asking for a judgment of values and implies for the decision maker to take responsibility for it, this being the difference between an ordinary issue and an ethical one [4].

Business ethics is commonly defined by a set of principles, standards and moral values specifically designed for the business environment [4]. One major conflict with ethics that appears in this field is represented by the natural desire of the companies to assure their survival, to grow and/or to obtain big profits. Another conflict is generated by the behavior that the companies encourage in their employees in order to achieve their

goals. Even if this second situation refers to individuals that take decisions within an organizational context and can be treated as work ethic or more precisely ethical work [6], it will be treated in this paper as part of business ethics as the companies are considered to determine the organizational setting of their employees.

2. The practical approach

The paper is based on a quantitative study that involved the use of a questionnaire. Information regarding the ethic courses completed by the students in secondary school or at university was requested. Also, the questionnaire included items regarding the gender of the subjects (previous researches have concluded that there are gender differences in the process of ethical decision making) [2] and their job experience (as this aspect was considered to have a potential influence over their ethical approach).

In order to measure the ethical standards of the students, six items were developed – 4 related directly with the organization interests and 2 related with the ethical work (the interests of the company were mediated by a supervisor). The items included in the questionnaire were measured using a five point Likert scale on which the students marked their degree of approval with the following situations: lying to clients, compromising their own values, supporting an unethical behavior from the part of the company, supporting an unethical behavior from the part of other employees, accepting to be lied by a supervisor and accepting a supervisor to ask them to cover an unethical conduct of a colleague (all of these in order to protect the company's interests). The Cronbach Alpha coefficient calculated for the six items was 0,614. Even if it is generally considered that a scale is reliable from a

value of 0,7 and that the results get better as the Cronbach Alpha coefficient tends to reach a higher value, some particular aspects should be taken into account such as the number and the nature of the items included. A large number of items, as well as a high similarity between the items, can artificially increase the value of the coefficient. A value greater than 0,9 may indicate some duplicate items and not a better scale. For such reasons a value between 0,7 and 0,8 can be considered to express a good internal consistency for a scale of ten items or more [3]. Values of the Cronbach Alpha coefficient between 0,6 and 0,7 are reported frequently by the researchers in their papers.

The sample was represented by 218 students of which 52.6% were women and 47.4 % were men. 97.2% of the students included were aged between 18 and 30 and 82.9% of the sample was represented by students in the third academic year. Most of the students were Spanish (82.6%), followed by Americans (7.8%) and other nationalities (9.6%).

3. The hypotheses

The first set of hypotheses is based on the assumption that the educational system is influencing the students' ethical perceptions. The general hypothesis is:

H1: the ethic standards of the students who took previous ethic courses will differ from the ethic standards of the students who didn't take previous ethic courses.

More than that, it is assumed that the independent ethic courses will have a greater impact than the ethic courses integrated within other disciplines (H1a). Also the ethic courses taken during the university period are expected to determine a higher score on the ethics scale (as they are supposed to be fresher into their memory) compared with the ethic courses taken during the secondary school (H1b).

The second hypothesis is based on the concept of "ethic of care" extracted from the literature review, a concept according to which the ethical conduct is sensitive to gender differences, the women being more ethical than the men due to their natural "care orientation" [1, 2]. The hypothesis is:

H2: the ethic standards of the male students will differ from the ethic standards of the female students (with the women obtaining higher scores on the ethics scale than the men)

The final hypothesis is based on the fact that job experience is usually affecting the perceptions of the students. As they had to respond to the ethic items in a virtual context of a company, it is expected that they will even project their own experience on that situation even will consider a theoretical case (if they don't have experience). The third hypothesis is:

H3: the ethic standards of the students who don't have a relevant job experience will differ from the ethic standards of the students with a relevant work experience.

4. The results

Testing the hypothesis implies the use of the parametric tests. Therefore, the first step was to test whether the distribution of the dependent variable (the scale that measured the ethic standards) is normal. The Kolmogorov-Smirnov test was applied and the result was a Kolmogorov-Smirnov coefficient of 0,945 with a sig value of 0,333. Thus the null hypothesis couldn't be rejected, so it was concluded that the distribution is normal.

In order to test the first set of hypothesis the ANOVA analysis was applied. The variable representing the independent ethic courses had four levels (depending on when the students took those courses):

- none (no independent ethic course taken until now)
- in secondary school
- in university
- in secondary school and in university

The test of homogeneity of variances was performed and the Levene statistics was 0,799 with a sig value of 0,495. Consequently the null hypothesis couldn't be rejected and it was accepted that the groups had approximately equal variances on the dependent variable, so the ANOVA analysis could be performed.

The ANOVA results showed an F value of 4,974 with sig = 0,002 confirming the fact that there is a significant difference between the groups regarding their ethical standards.

The Bonferoni Post Hoc test showed that there is a significant difference between the students who didn't take any previous independent ethic course and the students who took ethic courses both in secondary school and in university, with the latter group displaying higher scores on the ethics scale. The test also showed a significant difference between the students who took ethic courses in secondary school and the ones who took ethic courses both in secondary school and in university. Again, the second group obtained a higher score. There were no significant differences between the students who took ethic courses in secondary school only and the ones who took ethic courses in university only, so this assumption from the first set of hypotheses couldn't be validated (H1b). Also, it could not be tested whether the independent ethic courses had a greater impact than the integrated ethic courses (H1a) because all of the students included in the sample took integrated ethic courses.

In order to test the main hypothesis (from the first set of hypothesis) the T test for independent samples was applied. The value resulted was $t = -2,269$ with 216 df (degrees of freedom) and $\text{sig} = 0,009$, which suggest that H1 can be validated with a probability of 95%.

The T test for independent samples was applied again, this time for identifying whether there are gender differences. The group statistics displayed an average score on the ethics scale of 2,3314 with a standard deviation of 0,616 for men and an average score of 2,6879 with a standard deviation of 0,517 for women. The Levene test ($F = 2,362$ with $\text{sig} = 0,126$) indicated that the variances can be assumed to be equal, while the value of the T test ($t = -4,604$, $\text{df} = 213$ and $\text{sig} = 0,000$) has validated the second hypothesis (H2).

H3 stated that there will be differences in the ethic scores between the ones with no relevant working experience and the ones with relevant working experience. The cut point was decided at 1. The decision was made based on the data. Those with less than 1 year (without relevant experience) and those with 1 year or more (with relevant experience) are categories that have generated two approximately equal groups, and these categories also make sense from a conceptual point of view. The T test

confirmed the hypothesis ($t = 2,352$ with 216 df and $\text{sig} = 0,020$). With a probability of 95% it can be argued that the ethic standards of the students that don't have a relevant job experience differ from the ethic standards of the students with a relevant work experience.

The group with less than 1 year experience had a mean of 2,593 and a standard deviation of 0,606, while the group with one year experience or more had a mean of 2,400 with a standard deviation of 0,544. It can be concluded that the students with job experience tend to have lower ethical standards than the students without job experiences.

The analysis was continued by testing the influence of gender over the results of the T test regarding the job experience. The data base was split in two groups based on gender. The resulting groups were verified from the point of view of the cases included in each category and they proved to be valid (in the male group, there were 60 cases with less than 1 year experience and 42 with 1 year or more than 1; in the female group, there were 76 cases with less than 1 year experience and 37 cases with more than 1). The T test was performed again. For the male group we obtained $t = 0,244$ with 100 df and $\text{sig} = 0,154$, so it can be concluded that the H3 hypothesis can't be validated for this group. For the female group the results were: $t = 3,130$ with 111 df and $\text{sig} = 0,002$, hence the H3 hypothesis can be validated for this group.

5. Conclusions

From the 5 hypothesis, 2 were validated (H1 and H2), 1 was invalidated (H1b), 1 couldn't be tested (H1a) and 1 was partially validated (H3 was validated for the entire group and for the female subgroup, but not for the male subgroup).

The factors of variation of the ethical business standards of the students identified in this study were: gender, previous ethic course exposure and job experience.

The results showed that the students who took previous ethic courses have higher ethical standards than the ones who hadn't taken ethic courses before. This is an expected result, but what has to be taken into account is the fact that only the independent ethic courses were included in the analysis.

As mentioned before, all of the students took integrated ethic courses (an ethics chapter included in various books on different subjects). This result raises the importance of including ethics as a subject on its own in secondary school as well as in universities (the results also showed that students who have studied ethics both in secondary school and in universities have obtained a higher score on the ethics scale).

The gender influence over the ethic standards of the students is in line with the findings of other researchers. Still, the theme of the "care orientation" and the role played by gender in ethical decisions is a more complex one and the purpose of this study was not to enter into this field. As a consequence the variation of the ethical standards between the male and the female groups should be treated in the limits imposed by the purpose of this study.

Interesting is the result regarding the variable "job experience" as a factor of variation of the students' ethic standards. Apparently, the students with a relevant job experience have scored a lower point on the ethic scale than the students with no relevant job experience. From this result, it can be speculated that the ethical standards are more important from a theoretical point of view than from a practical one. It can also be speculated that there is a possibility to consider that the students lose part of their ethical principles as they enter into the work market or as they gain more experience. But only a future study designed for this specific purpose can validate or invalidate these assumptions.

The results of this study have to be taken into account bearing in mind its limitations. The sample, even if it was represented by students, included some outliers on descriptive variables like age (38, 40 or 51) and job experience (20 or 35 years of experience), that weren't excluded from the analysis. The subjects also were of various nationalities (82.6% Spanish and 17.4 foreigners) while some researches consider that the nationality and the culture can influence the ethical standards of the students. In these conditions it is hard to say what kind of population could represent this sample.

Another limit is related with the number of factors of variation included in this analysis. Other factors besides gender, previous ethic course exposure and job experience can also have an impact on the ethical business standards of the students.

Still, the study has explored the relationship between the ethical business standards of a group of students and some of the factors that influence them, and can be considered a point of departure for future research in this field.

Abstract

The social, economic and political evolution, which took place in the last decades and is still taking place, has created the premises of a significant changing, as far as the migration is concerned, imposing the necessity of a special attention to be given to these problems, which are more and more approached inside the political dialogue and international cooperation.

Key words: economy, migration, labor force, international

J.E.L. classification: F22, F16

An etymologic definition of the term of "migration" is more than necessary. The term comes from the Latin "migratio, -onis", and, according to DEX, it represents a massive displacement of tribes and populations, from one territory to another, caused by economic, social, political and natural factors. [1]

Migration is a complex phenomenon, consisting in the displacement of one person from one territory to another, followed by a changing of domicile and/or by employment in a form of activity, in the area of arrival. [2]

This way, the migration represents a displacement carried on with the view of changing the living and labor place, this changing being caused by social, political, economic or natural factors. Under these circumstances, this movement becomes not only a reaction against external pressures or an escape from them, but, also, a positive value itself and an affirmation of liberty.[3]

The population's migration is the main form its geographic (spatial) mobility, consisting in a definitive changing of

domicile from one well-defined administrative unit to another.

It is, also, called *residential migration*, as the person involved in such a movement changes his/her residential status. [4] Consequently, population's migration does not mean trips, temporary movements or different types of "to and from." That is why, it is important to have a correct definition of the geographical or administrative/territorial units and of the types of the population's movements.

The new theories [5] state that all the significant forces governing the international migration have the same direction: because the economic discrepancy between the rich and the poor countries remains considerable, and the number of the working-able adults, from the industrialized countries is diminishing, the migration will, inevitably, grow. Pritchett, cited by Timothy J. Hatton, considers that "inside the global economy, there are irresistible forces which generate higher and higher pressures in the direction of a greater circulation of the labor forces, from the poor countries towards the richer ones".

The migration measurement [6] can be done by means of calculating the *migratory balance* – the difference between the number of immigrations and that of emigrations. A positive migratory balance (the number of immigrants is greater than that of emigrants) means that the respective administrative-territorial unit exercise a certain attraction for other countries' populations. The greater this balance, the higher is the attraction force and the plus of population. A negative migratory balance (when the number of emigrants is greater) indicates a lack of attractiveness, in the respective area. The greater the migratory balance, the higher the lack of attractiveness.

In the 20th century, the international migration, together with the mobility of capitals, technologies and information, became one of the essential factors of globalization. Migration has always been part of the social changing, at a global level, such as: colonization, industrialization or world wars. The last 40 years have brought a doubling of the emigrants' number, at world-wide level, although the percentage of emigrants, in the global population, has remained constant. At present, there are 175 million emigrants, in the world, in other words, 3.5 % of the global population. One of the most important forms of the international migration is *the labor force migration*. The acknowledged objective of this form of territorial mobility is that of determining a social mobility, by means of changing the social status of the migrating person, a very important object of study for the sociologists.

Following the '90s crash of the socialist system, the East-European countries joined, again, to the world's economy. Migration is very important for the countries from this region, since they are involved as origin/destination countries in one of the world's most important migratory pattern. As it becomes a life strategy [7], the circulatory migration of the labor force was analyzed by sociologists, under the present circumstances of being one of the most dynamic forms of social mobility.

The labor force circulation [8] is defined as a movement of the working-able population (input/output flows, net stock), inside the international space, inter-countries.

From the perspective of the European population aging, the labor force emigration becomes more and more important. While the economic factor continues to motivate migration, the migration will more and more depend and be structures by demographic evolution. The aging process of the West-European population creates a lack of labor force, which will be solved by the active East-European population, from the less developed countries. Emigration of the active population from these countries brings about a lack of labor force which, by way of reciprocity, will have to be solved with emigrants from less developed countries, most probably from Asia.

The migration problem is much more ample, since the official statistics presents a certain number of emigrants, which, in fact, seems to be much greater. Departure of one or of both parents to work abroad has become, very quickly a social phenomenon, being considered as a viable alternative for solving the financial problems of those families which have a modest economic condition.

The International Organization for Migration – IOM has confirmed that, at present, the amplexness of this phenomenon is not enough known, and, that there are no certain statistic data to reflect the proportions of migration, all over the world, and to permit a correct evaluation leading to adequate policies. The social consequences of migration are as important as its influence upon economy.

The most recent reserach [9] of IOM presents the following demographic profile of the emigrant:

- Mainly of male gender;
- Between 15 and 44 years;
- Urban residence;
- High school or vocational school graduate;
- Performs non-manual works;

These statistic references indicate the amplexness of this phenomenon, as well as, the inherent difficulties in rigorously measuring and analyzing the different aspects of the migration phenomenon. Nevertheless, a complex analysis of the family condition from the perspective of the internal displacements and of the social status dynamic is necessary.

The International Convention regarding the "Protection of the rights of all the migrant workers and of their families' members" [10] contains, among others, the following items:

- Defines the concept of "migrant worker", in a larger sense, including, at the same time, the trans-border workers, the navigating staff and the professionals; the civil, political, economic, social and cultural rights presented in this convention are applicable to all the migrant workers (with or without valid documents) and to their families' members;

- Pronounces distinctly, in a larger sense, the principle of equal treatment between the migrant workers and the workers

of the hostess country, regarding their remuneration, working conditions and access to medical and emergency assistance;

- Provides more extensive rights for migrants, regarding the transfer of money (earnings and savings) from one country to another;

Causes of labor force international migration

The main causes of an increased mobility of the active population are of *economic* nature. They can be structured as follows:

- The significant *economic discrepancy* [11] between the origin countries and the countries of the migrating flow destination; the best way of directly measuring this discrepancy is to consider the pay/hour for the same activity; in many cases we speak about need of survival, in others, about the need to correlate the low level of incomes and the high level of individual aspirations; as it is well-known, these two aspects never correlate with each other;

- Competition and prices liberalization*, characteristic for the domestic market of goods and services, have generated, in a very short time, a comparable level of prices, and, consequently, a life cost high level as compared with wages level; maybe not by chance, a positive correlation between the real estate market (rent and houses prices) and the migration; their very high level frightens and leads to the decision of leaving the country; the present lowering of these prices could contribute to the decision of coming back;

- The existence of a *high demand for cheap and/or qualified labor force*, in the developed EU countries, as well as, in USA and Canada; in order to correctly assess the number of those who return in their countries, it is important to be known whether the economic crises and its demands for efficiency has significantly lowered the labor force demand and, if yes, in what domains;

- The existence of *poor offer on the labor domestic market* is on the last place; we are not speaking about a lack of working places, but about the fact that they are badly paid (a typical example for this situation is that referring to medical doctors and nurses; more

that a half of the positions are vacant, but the nurses continue to leave the country; the explanation is that, in other countries, there is a great demand, the wages are more attractive, even if the work performed is under the professional training level). The economy, as well as, the society low capacity of generating working opportunities and an encouraging remuneration, stimulates the exodus of qualified and highly qualified labor force, as well as, the exodus of intelligence and insufficient labor force in the countries the migrants come from. [12] In some countries, the emigration of young workers has determined a certain concern regarding the intelligence exodus and insufficient labor force. Some reports show, indeed, that, in some countries, the Baltic states, for example, the emigration has contributed to the decreasing of the labor force.

- Nevertheless, in many countries, the labor force decreasing has been aggravated by *factors, others than the emigration*, such as: a strong economic growing, a relatively weak participation on the labor force market, especially of young and aged people, as well as, a low domestic mobility. Additionally, the labor force decreasing influences the major part of the specialized economy sectors (for example, constructions, hotels and reconstruction sectors) and those of professions (medical assistance, for example). At the same time, the differences regarding the variations of competences between the emigrants and the labor force from their origin country seem to be, relatively, moderate, suggesting that, generally speaking, the intelligence exodus is possible to be a phenomenon with a limited character.

- An essential cause [13] may be found in *over-population processes*, marked by a rupture between the number of population and resources; the effect is a lowering of incomes and impossibility of satisfying consume. Over-population can be determined by a surplus of births dominating the mortality ratio, a situation specific, mainly, to the less developed countries. Such a situation has characterized, in the 19th century, the Western Europe, when the lowering of mortality compensated the weakening of fertility.

•In some other countries, *the intensive animal breeding* has favored labor force dismissal, which, afterwards entered under the migration incidence;

•In some other situations, *the development of communication ways* has favored the spreading of industries, a phenomenon which asks for labor force and stimulates a part of the population to enter into the migration flow. The sea transport, and, in a smaller extent, the railway transport have favored the international migration;

•At the same time, the migratory movements can be determined by *historic, religious and political* reasons, which can be considered as being accidental and current causes;

•The increasing of the international migration level can be, also, caused by *legislative system* [14] transformations, namely by persons' free circulation;

•*Disasters and diseases* can be, also, considered accidents causing massive and sudden immigrations and emigrations;

•*Psychological* type causes have in view the fascination of some places, relief or landscapes. This way, the places chosen by a group from a certain population, can become attraction poles for their countrymen. The following examples are classical: Barcelonette – a colony in Mexico, colony-quarters in USA and in Western Europe;

•*Ecologic causes* determine the so-called *ecologic migration*. This kind of migration happens when populations move from regions affected by environmental and entropic transformations, towards another places. Mexico-City, Milan and Athens are extremely polluted cities and can be discomfort and emigration centers for their population;

People migrate from various reasons. They take into consideration various *factors*, such as: distance, travel costs, travel duration, type of transport, climate and cultural barriers.

•*The push factors* [15] represent reasons for leaving a place and emigrate due to certain difficulties: war, starvation, floods, etc. they can be economic, political, cultural and environmental factors.

•*The pull factors* represent reasons to emigrate (to settle in a certain place) due to some opportunities offered by the respective location: working places, a better climate,

liberty, etc. they can be economic, political, cultural and environmental factors.

Many push and pull factors can influence the population to migrate, sometimes, simultaneously:

1. Environmental factors
2. Political factors
3. Economic factors
4. Cultural factors

•*Utility of location* – the opportunities existent in a certain location, based on the respective region social or economic conditions, are used for comparing the living level in different places. One individual's ideas about the location utility can reflect or not the real conditions existent in the location.

•*Intervention opportunities* – the opportunities offered by neighboring regions are, usually, considered more attractive than better opportunities from locations at greater distances. If the factors are equal, the migrants tend to settle in a location close to their origin location.

•*Shortening of distance* – the longer the distance to a certain location, the lower the understanding of the respective location specific. There is a high probability that people settle closer, in a place about which they know more things, than in a place located at a greater distance and about which they do not have much information.

Those who study the causes of migration realize that the **migration recipe** [16] represents one of the motive forces of the migratory phenomenon. The "*friends and relatives*" effect, reflected at the destination, proves to be a variable of a maximum importance. The fact that a migrant has friend and relatives, at destination, can diminish the costs and uncertainty associated to migration in a far unfamiliar location. This way, the existence [17], the arrival place, of a group of relatives, for example, can contribute to the lowering of migrant's integration costs.

Of course, there are several forces governing the emigration life cycle, others that travel costs and differences between source and destination wages. One of them is the **population age structure** [18]: migration is a progressive decision, focused on future and extremely important for young adults, who having no persons to care of, can confront with lower prices.

Education is often regarded as other fundamental force acting upon the migration. Observers sustain that, sometimes, *illiteracy* can be an obstacle for migration, as it limits and restricts the potential migrants' access to information flow. Moreover than that, illiteracy can block the migrants' access to working places for which they could otherwise have been eligible.

Vasile Valentina and Zaman Gheorghe, [19] in their volume "Labor force migration and Romania's durable development" present the following main causes of migration from one country to another:

- Economic recession, unemployment, low incomes, lack of opportunities and career perspectives or very few one;
- Poor, unsatisfactory social conditions, politically, inclusively;
- Instable, non-friendly and unpredictable business environment;
- Problems in connection with marriages and family unification;
- Aspects in connection with penal problems, environment and climate;

Six factors, [20] acting at combined levels (individual, family, husbandry, community, origin region and destination) are responsible for the cumulative character of international migration:

- Distribution of the husbandry incomes at the community level (or the relative deprivation);
- Land distribution and the agrarian way of organization, the origin community level;
- Culture of migration (origin community);
- Regional distribution of the human capital (origin region);
- Social assessment (destination region);
- Migrants' networks and institutions;

The Impact of Mergers on Firm Performance

Sandu Chiriac Irina

„Alexandru Ioan Cuza” University of Iași

irynasan@yahoo.com

Abstract

Mergers are transactions of great importance, not only for the organizations involved, but for many stakeholders. Success or failure of such enterprises may have huge consequences for the shareholders of an organization, creditors, employees, competitors and communities. Empirical evidence indicates a high rate of failure of mergers in terms of value creation for shareholders. This study examines the impact of the merger on the performance of companies in Romania. Performance in this analysis is defined as debt rate and the biggest influence on the performance on merged firms is the share of current assets to total assets.

Key words: mergers, performance, borrowing rate, current assets to total assets.

J.E.L. classification: C12, M41.

1. Introduction

Financial and economic crisis covered the entire world and its consequences are difficult to assess. One thing is certain-the fear of tomorrow, with all its consequences. In this framework of uncertainty and unknown, the only salvation for companies to strengthen a certain position on the market and gain advantages in terms of the transaction tax is to restructure the company by merger.

Many writers and business analysts have argued that mergers are doomed to failure and the merger success is somehow in contradiction with the reality of business world. Of the total of merging companies 80% of them do not create value.

In fact, most mergers are proving a difficult process, with unknown risk that ultimately translate into a loss of sales, and especially with the loss of valuable people in

the organization. A fair and disciplined approach to the merger increase the chances of success.

2. Conceptual framework

In attempt to define performance we track several points of view.

Friedlander and Pickle (1968) include the following criteria to assess performance: profitability, employee satisfaction, the value of the company.

Duncan (1973) assimilates performance with the following objectives: integration and adaptation.

Klein (1976) define performance as a: adding value, return on capital employed, growth of fixed assets, term debt relative to cash flow capacity.

However the best approach of performance is through the definition: performance is the achievement of organizational objectives.

Performance depend on the reference: objective or purpose, it is multidimensional because the goals are multiple.

A performance is not good or bad in itself. The same performance can be assessed as a good performance when the target is small or poor performance when the target is ambitious.

An enterprise that is performant is the enterprise which creates value for shareholders, satisfy customers, take into account the opinion of employees and respect the natural environment. Thus the shareholders is satisfied because the company has achieved the desired return, enterprise customers are confident in the future and quality of products and services, employees are proud of the company where they work, and the company enjoys the company policy on environmental protection.

Analysis of performance by analyzing financial statements include profitability analysis, solvency analysis, liquidity

analysis, management analysis of intermediate balances, earnings per share analysis and analysis of explanatory notes to the financial statements.

3. Empirical study

This paper aims to study the link between a number of variables that characterize the financial performance - defined as debt rate - of companies that have merged (rotational speed of current assets, proportion of current assets to total assets, income rate and company size), with the ultimate aim of generating a statistical regression model to analyze if there is a link between independent variables and the rate of debt and to determine which factor has the greatest influence on the performance of firms that have merged.

H_0 : There is no significant relation between the performance of firms that have merged and the rotational speed of current assets, proportion of current assets to total assets, income rate and company size.

H_1 : There is significant relation between the performance of firms that have merged and the rotation speed of current assets, proportion of current assets to total assets, income rate and company size.

H_{11} : The biggest influence of the rate of debt has rotational speed of current assets (Nac);

H_{12} : The biggest influence of the rate of debt has proportion of current assets to total assets (Sac);

H_{13} : The biggest influence of the rate of debt has the income rate (Rv);

H_{14} : The biggest influence of the rate of debt has the company size (D).

3.1 Description of variables in the regression model involved

The study was conducted in Romania, using data collected for the period 2007 – 2009 and the source of information is represented by the Trade Register Office attached to Iasi Tribunal. The nature and characteristics of variables used in the model are summarized in Figure 1.

Figure 1. Variables used in the econometric model

Variables	Economic expression	Statistical expression
Ri	Debt rate $Ri = \frac{Debt}{Assets}$	Dependent variable Resultative variable Quantitative dimension Numerically expressed as a percentage
Nac	Rotational speed of current assets $Nac = \frac{CA}{Ac} * 100$ CA = turnover Ac = current assets	Independent variable Predictor factor Quantitative dimension Numerically expressed as a percentage
Sac	Proportion of current assets to total assets $Sac = \frac{Ac}{A} * 100$ Ac = current assets A = total assets	Independent variable Predictor factor Quantitative dimension Numerically expressed as a percentage
Rv	Income rate $Rv = \frac{Vt}{Cht} * 100$ Vt = total income Cht = total costs	Independent variable Predictor factor Quantitative dimension Numerically expressed as a percentage
D	Size company Represents the number of employees of the company	Independent variable Predictor factor Quantitative dimension Numerically expressed as a percentage

Source: SPSS tools

In the methodological approach was used multiple regression model using SPSS 17.0 tools.

The equation of the regression model is expressed as:

$$Ri = \alpha + \beta_1 * Nac + \beta_2 * Sac + \beta_3 * Rv + \beta_4 * D + \xi$$

where:

- α, β are regression coefficient;
- ξ is random variable error;
- Ri is the dependent variable;
- Nac, Sac, Rv, D are independent variables.

3.2. Methodological approach and the interpretation of the results

Correlations figure displays Pearson correlation coefficients (Pearson Correlation), the significance (Sig.) for each correlation coefficient and number of cases studied (N).

Figure 2. Partial correlation matrix

Correlations						
		Ri	Nac	Sac	D	Rv
Pearson Correlation	Ri	1,000	-,173	,999	,241	-,169
	Nac	-,173	1,000	-,182	,153	-,105
	Sac	,999	-,182	1,000	,241	-,152
	D	,241	,153	,241	1,000	,082
	Rv	-,169	-,105	-,152	,082	1,000
Sig. (1-tailed)	Ri	.	,176	,000	,096	,182
	Nac	,176	.	,164	,206	,287
	Sac	,000	,164	.	,096	,207
	D	,096	,206	,096	.	,331

Source: SPSS tools

In the figure is presented the relationship between each independent variables with dependent variable $R\hat{i}$ – debt rate.

Is noted that the diagonal coefficient of correlation is equal to 1, because each variable is perfectly correlated with itself.

It appears that the most significant relationship is between the rate debt ($R\hat{i}$) and proportion of current assets to total assets (Sac).

Between the dependent variable – $R\hat{i}$ – and the independent variable – Sac - there is a strong direct relationship, the correlation coefficient is equal to 0,999 with a value Sig. less then 0,05.

Figure Variable Entered/Removed provides an overview of the results of the variables elimination step.

Figure 3. Variables entered into the model and variables eliminated step with step

Variables Entered/Removed ^a			
Model	Variables Entered	Variables Removed	Method
1	Rv, D, Nac, Sac	.	Enter
2		D	Backward (criterion: Probability of F-to-remove >= ,100).
3		Nac	Backward (criterion: Probability of F-to-remove >= ,100).

a. All requested variables entered.
b. Dependent Variable: Ri

Source: SPSS tools

Thus are eliminated variables, one by one, in order of weakest influence on $R\hat{i}$, the variable D, variable Nac and the variable Rv.

Model Summary figure presents for each regression model the coefficient of correlation (R), the coefficient of determination (R^2) and the standard error. R value increases as more variables are introduced into the model. The inclusion of irrelevant variables also leads to increased standard error.

The study found the correlation between model variables through the value of coefficient of determination $R^2 = 0,99$ (for all independent variables) shows that 99% of the variance in performance of the merged firms may be explained by the influence of independent variables (Nac, Sac, D, Rv).

The difference is attributed to conjunctural factors. Sig. is less than the acceptable upper limit 0,05 showing that linear model is validated by the value of sig. This means that the risk of being wrong that is a strong correlation between the variables is less than 5%.

Sig. value less than 0,05 suggest that the linear model is most appropriate to express correlation between variables. This step of analysis is shown in the figure below:

Figure 4. Model Summary

Model Summary ^d				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	,999 ^a	,999	,998	56,76692
2	,999 ^b	,999	,999	55,74062
3	,999 ^c	,999	,999	55,51501

a. Predictors: (Constant), Rv, D, Nac, Sac
b. Predictors: (Constant), Rv, Nac, Sac
c. Predictors: (Constant), Rv, Sac
d. Dependent Variable: Ri

Source: SPSS tools

R value, adjusted R² value and standard error indicates that the best predictor (independent variable which best estimates the dependent variable) is variable Sac – the proportion of current assets to total assets.

The same conclusion can be drawn considering the results of below figure:

Figure 5. Anova

ANOVA ^d						
Model		Sum of Squares	df	Mean Square	F	Sig.

c. Predictors: (Constant), Rv, Sac
d. Dependent Variable: Ri

Source: SPSS tools

If statistical significance F value is low (Sig. is less than 0,05) the independent variables explain the dependent variable variation. The lowest value Sig. corresponds to the model explaining the variation of R_i according to Sac - the proportion of current assets to total assets.

In the figure of regression coefficients, in the first part, appears regression coefficients, standard errors, the t – test statistics for each factor, and the amount Sig. and statistics of collinearity, tolerance and the variance inflation factor (VIF).

Collinearity express a strong correlation between independent variables. So tolerance statistics is calculated, considering only the independent variables, dependent variable is excluded from the model.

The tolerance of each variable X_i is calculated by the formula:

Tolerance = 1- R_i², where R_i² is squared multiple correlation coefficient of the variable X_i, with all independent variable.

VIF is the reciprocal of the tolerance.

Tolerance can range from 0 to 1. As the tolerance is less, closer to 0 the independent variable X_i is more explained by a linear combination of other independent variables. Therefore, this variable explain the dependent variable can be regarded as having too little accuracy.

Figure 6. Regression coefficients

Coefficients ^a										
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	95,0% Confidence Interval for B		Collinearity Statistics	
		B	Std. Error	Beta			Lower Bound	Upper Bound	Tolerance	VIF
		1 (Constant)	41,868	27,667				1,513	,142	-15,003
	Nac	,044	,055	,006	,800	,431	-,069	,157	,900	1,111
	Sac	1,240	,010	,997	128,83	,000	1,220	1,259	,853	1,172
	D	1,209	6,704	,001	,180	,858	-12,570	14,989	,880	1,136
	Rv	-,358	,161	-,016	-2,220	,035	-,690	-,027	,935	1,069

a. Dependent Variable: Ri

Source: SPSS tools

The equation of the regression model, based on the data presented above is as follows:

$$R_i = -41,868 + 0,44 * Nac + 1,240 * Sac + 1,209 * D - 0,358 * Rv$$

The regression coefficients are: $\alpha = -41,868$, $\beta_1 = +0,44$, $\beta_2 = + 1,240$; $\beta_3 = +1,209$; $\beta_4 = 0,358$.

The model reflects the influence of rotational speed of current assets, proportion of current assets to total assets, income rate and company size on performance of the merged companies (debt rate):

- *If we maintain constant:* the proportion of current assets to total assets, income rate and company size, a percentage increase of the rotation of current assets lead to an increase performance of firms that have merged in an average of 0,44%;
- *If we maintain constant:* the rotation of current assets, income rate and company size, a percentage increase of the proportion of current assets to total assets lead to an increase performance of

firms that have merged in an average of 1,240%;

- *If we maintain constant:* the proportion of current assets to total assets, rotation of current assets and company size, a percentage increase of the income rate lead to a decrease performance of firms that have merged in an average of 0,358%;
- *If we maintain constant:* the proportion of current assets to total assets, rotation of current assets and income rate, a percentage increase of company size lead to an increase performance of firms that have merged in an average of 0,358%.

Collinearity diagnostic requires analysis of the results in the figure 7.

Eigenvalue gives an indication of the number of links that exist between independent variables. When several eigenvalues are close to 0, the variables are strongly interrelated.

The correlation indices are calculated as the ratio of the square root of the largest eigenvalue and value eigenvalue of each size.

An index above 15 indicates that there is a potential problem to collinearity, and a value greater than 30 indicates serious problems of collinearity. These situations are not encountered in this analysis, hence there is a strong correlation between independent variables.

Figure 7. Collinearity diagnostic

Collinearity Diagnostics ^a								
Model	Dimension	Eigenvalue	Condition Index	Variance Proportions				
				(Constant)	Nac	Sac	D	Rv
1	1	3,321	1,000	,01	,02	,01	,02	,02
	2	,996	1,826	,00	,02	,75	,00	,01
	3	,404	2,866	,00	,55	,01	,00	,28
	4	,181	4,280	,00	,26	,22	,71	,34

Excluded variables figure provides information about variables that are excluded at each step

Figure 8. Excluded variables

Excluded Variables ^a								
Model	Beta In	t	Sig.	Partial Correlation	Collinearity Statistics			
					Tolerance	VIF	Minimum Tolerance	
2	D	,001 ^a	,180	,858	,035	,880	1,136	,853
3	D	,003 ^b	,374	,711	,072	,928	1,078	,912
	Nac	,006 ^b	,880	,387	,167	,949	1,054	,937

a. Predictors in the Model: (Constant), Rv, Nac, Sac
b. Predictors in the Model: (Constant), Rv, Sac
c. Dependent Variable: Ri

Source: SPSS tools

The Beta in coefficient is the regression coefficient that would arise if in the next step would preserve the excluded variables in the model.

T-test statistics and the value of Sig. are used to test the null hypothesis as regards their regression coefficients, that is the assumption that between the independent variables and the dependent variable there is a significant connection.

So it appears Sig. values very big (compared with 0,05), which allows as to reject the null hypothesis, the absence of a relevant links between dependent variable – Ri – and independent variables – Nac, Sac, Rv, D.

Compliance with the assumption required to regression analysis (errors are normally distributed, variance of errors are constant, the errors are independent of each other) can be checked using P-p plot and the histogram.

Figure 8. Hisogram

Figure 9. P-p plot

Source: SPSS tools

4. Conclusion

In the regression analysis it is found that there is a significant relationship between the dependent variable and independent variables which leads to invalidation of the null hypothesis H_0 : *There is no significant relation between the performnace of firms that have merged and the rotational speed of current assets, proportion of current assets to total assets, income rate and company size.*

The performance of the firms that merged (performance defined as debt rate) was influenced most by the proportion of current assets to total assets.

Because the relationship between R_i and Sac is direct appears that an increased performance is determined by the high proportion of current assets to total assets.

So the valid hypothesis is H_1 : *There is significant relation between the performnace of firms that have merged and the rotation speed of current assets, proportion of current assets to total assets, income rate and company size with H_{12} : The biggest influence of the rate of debt has proportion of current assets to total assets (Sac).*

Is there a Need for Public Expenditures during Economic Crises?

Sava Anca-Ştefania

"Alexandru Ioan Cuza" University of Iasi, Doctoral School of Economics
sava.anca@yahoo.com

Abstract

The aim of this paper is to discuss the need for using public expenditures during economic crises. Firstly it presents an epistemological approach to the concept of public expenditure and underlines the resurgence of the Keynesian paradigm in the current crisis, whereas governments with an important share in the global economy have attempted through fiscal budgetary stimuli to avoid an economic decline. Secondly, the paper analyzes the evolution of public expenditures in Romania in the last years, according to which unproductive spending prevailed, in detriment of productive investments. The paper advocates the need for capital investments which can foster economic growth.

Key words: public expenditures multiplier, the welfare state, Classical School of Economics, Keynesianism, economic crisis

J.E.L. classification: H53, I38, B12, E12, G01

1. Epistemological approach to the concept of public expenditure

The opinion of classics Adam Smith, David Ricardo, J.B. Say, J.S. Mill and other economists on society has its roots on the ideas of economic liberalism, summarized in the phrase "laissez faire, laissez passer, le monde va de lui meme", that means non-government intervention in the economic activity. The invisible hand allows the harmonization of private interests with the general interest of society. Politically, this doctrine was established on the principle that the economic activity was excluded from the scope of the state, which entails a limitation of interventions financed by the state.

Thus, classics oppose to state intervention in the market mechanism in providing restrictions on imports and incentives for exports, against any governmental laws aimed to protect local industry against competition and against government spending for unproductive purposes. Smith, but also followers of liberal doctrine think that the socio-economic system cannot function only in the case of creating a public institutional apparatus. In other words, intervention is permissible, but with limitations on the field of public intervention on private initiative. Smith does not preclude state intervention in any way, but only if advocates actions "aimed at promoting the general welfare", if increases happiness and the prosperity of the community.

From classics works we can identify the character of finality, embedded, of consuming values of public expenses, which affects the size of gross domestic product and leads to a reduction in national wealth, thus having a negative impact on capital reproduction and prosperity of the nation. State activity was considered to be counterproductive, serving only for consuming resources in order to implement measures publicly funded from public resources. The fact that the budget must be balanced had a deeper meaning than equality of income and expenditure, thus becoming a means of constraining state actions, achieved by limiting public spending.

In his book "An Inquiry into the Nature and Causes of the Wealth of Nations", Adam Smith specifies which expenditures were made by liberal state: public defense expenditures, expenses for the administration of justice, public works spending and for public institutions and another type of expenses were intended to support the state rank.

Public defense expenditure was treated as a first duty of the state to protect the members of the society from violence and

damage of other persons and societies and was more expensive as the society became more civilized. Adam Smith noted that in modern war, higher defense spending advantages wealthy and civilized nations compared with the poor and barbarous, which were favored in ancient times. He stresses the role of undisputed standing armies, well disciplined, the country's defense against barbarian invasions from the neighbors [1, p.159]. A second category of expenditure is the expenditure for the administration of justice, for protection against unjust of other society members. Such costs, as those for public defense, impose a general contribution of members, although Adam Smith criticized this, saying that "expenditures for the administration of justice could be done very fairly through specific contributions of one or another or both categories, as they are required in different occasions, as fees paid to courts" [1, p. 235]. A third state responsibility concerned public works and public institutions which bring more benefit to society, given that individuals cannot maintain them, because profits would not cover. Adam Smith noted that the expenditures incurred by the state were not absolutely necessary covered from public revenues, but on the account of some special revenues, as fees for vehicles passing over a road, bridge or waterway. Also, for facilitation of certain trade branches, special institutions were needed, which in turn required special and extraordinary expenses from the executive power.

State was also spending for education, instruction, especially a religious one.

Classics, but also neo-classics believe that fiscal policies designed to increase public expenditures are inefficient in the context of the well-known phenomenon of "crowding out", because by increasing public expenditures, public goods are replaced with private ones, resulting a low level of private expenditure on health, education, transport and other goods and services.

The social and economic philosophy of *laissez-faire*, that all citizens share a single political ideal, namely the welfare of the whole nation was replaced during the economic crisis of overproduction in the years 1929-1933 by the interventionist doctrine. Keynes ideas had a radical impact on both modern economic and political

theory, as well as on many governments' fiscal policies, proposing the solution of government intervention to prevent and correct imbalances that had arisen.

The state must fill weaknesses in private sector investment, because "market alone is not able to show entrepreneurs what it is the right level of investment (the one corresponding to full use of labor)" [2, p.141].

Social democratic governments emphasizing the protection offered by state to social disadvantaged groups favor the intervention through public spending and thus achieve a higher redistribution between members of society. It prevails the idea that the role devolving upon the welfare state contributes to a largely redistribution of the product created.

In the General Theory, Keynes opposes to state socialism, to moving production tools in public ownership, stating that "a fairly comprehensive socialization of investment will prove the only way to ensure a high occupancy close to full employment" [3, p.380].

He supports state intervention in the economy taking into account the stabilizing role of public spending and investment multiplier. To stimulate investment, Keynes talks about the possibility of public action by the central bank, the level of interest rate on the market, but also directly, through grants, purchases of goods and services by governments etc. Thus, in times of economic downturn, the central bank takes measures to reduce interest rates, which will support loans, will increase consumption, will increase aggregate demand, the employment of workers and thus will ensure the economic recovery.

Keynes included public spending in the equations of general equilibrium. Thus, public expenditure, both for public consumption and public investment, was equivalent to the aggregate consumption demand, as a variable which makes the offer. The premises of these interpretations offered to public spending are reflected in the fundamental psychological laws made by Keynes namely: marginal propensity to consume, marginal propensity to save, investment law and the propensity to liquid values [4].

Expenditures' dependence to revenues was first studied by Engel, who found different elasticities of consumption relative to income. Keynes defines the functional relationship between community income and the amount that can be expected from a consumer to spend as propensity to consume, measured in units of salary, to eliminate variations in the purchasing power of income expressed in monetary units. Keynes calls the national income which does not cover the individual consumption as „savings”, representing the excess of income over consumption expenditure.

As income increases, saving size is bigger and more important in the years of prosperity and for the richest regions, in contrast to periods of war or depression and poor regions. Keynes provides a list of mobiles, which means that individuals save for: caution, foresight, thirst for prosperity, independence, business spirit, pride and avarice and their intensity varies according to economic society institutions and organizations that we consider, according to habits formed under the influence of racial belonging, the degree of instruction, conventions, religious beliefs and moral principles etc. Thus, for an individual saving becomes a security issue against risks such as illness, death, accidents, while at higher levels, such a decision is taken to “increase economic freedom of action” [5, p.115]. Also, propensity to save must be considered taking into account the different social classes and periods of development.

Another fundamental psychological law is the propensity to invest or the marginal efficiency of capital, a concept defined by Keynes as the ratio between „the future return of an additional unit of capital and the cost of producing that unit” [3, p.159].

The third law is the fundamental psychological law of propensity to liquid values. According to Keynes, liquidity preference is a psychological term that explains the behavior of individuals to keep assets in cash or bank, to the detriment of investment in shares.

Public expenditure multiplier expresses the income and production growth resulting from an increase in total public expenditure without adjusting tax amount, which conducts to an increase or to a budget deficit, financed via borrowing [6, p.345].

Keynes's ideas were supported and developed by Hansen, Samuelson, Schultz and others. Samuelson reconsidered keynesian and classical ideas, arguing that economic theory must combine with the free market mechanisms of state regulation in a single facility. Therefore, according to his opinion, the economy is not governed strictly by the ratio of market supply and demand, but also contains elements of public control. Samuelson says: “As the country's main economic entity, state, through its public expenditures, has an important role in determining patterns of consumption, investment and profits in the economy” [7, p.368].

The argument that fiscal policies contribute to economic growth has gained support with the introduction of the new theories of growth. Unlike the neoclassical growth model formulated by Solow (1956), which does not describe the channels through which public expenditure can influence long-term growth, economists Romer (1986) and Lucas (1988) suggest a possible long-term effect of public spending on growth.

Keynesian school of thought supports the idea that public expenditure is a component of budgetary and fiscal policy that can be used as a tool in order to influence economic growth. Some empirical studies, such as that made by Ansari et al. (1997) support this viewpoint, basing on an analysis for Ghana, Kenya and South Africa.

Wagner Act (1890) suggests, on the other hand, a reverse causal relationship between public expenditure and economic growth than the one presented by Keynes. Under that law, in the process of economic development, public expenditures tend to rise in order to expand the relative national income. This idea is supported by three assumptions: public function replace private activity, the results that economic development has on expanding cultural and welfare expenditures and the last refers to the fact that public intervention may be necessary to finance natural monopolies. In other words, increased public expenditure is seen as a result of economic development and not vice versa.

Both cases on the direction of causality between public expenditure and economic growth have been tested empirically in a study [8] for Malaysia, a developing country, using data series for 1970 to 2004. Both

hypotheses were supported for all categories of expenses analyzed: the education, health, defense, development, agriculture and administration.

Also, Iniguez-Montiel [9] examines the relationship between public expenditure and national income for Mexico, for a period of 50 years (from 1950 to 1999), using empirical approaches to test Wagner and Keynes law. The data confirmed a causal relationship between GDP and public expenditure (the Wagner Act), in other words, increased public spending or the size of the Mexican public sector has been identified as being positively correlated with the country's national income, while public expenditure was not a good fiscal policy tool to encourage or lead to national economic growth for the period under review (the Keynes's law).

In addition to these opinions and analyses based on the fundamentals of Keynesian doctrine also gained importance the neoliberal doctrine, known as the model of "supply-side economics", having as foreground the contemporary "monetarism". Under this doctrine, public expenditures are considered less effective, even unacceptable to support balanced economic growth. Also, monetarists view that "instead of differentiated government actions, self-regulating mechanisms that impede the action of the market, compliance with rules is preferable to monetary developments" [10, p.54].

2. Analysis of the Romanian economic structure of public expenditures during the current economic crisis

In Romania, concentrated at the general government, public budgetary expenditures in the period 1992-2010 have recorded substantial increases in nominal size, of 808.3 times, while gross domestic product increased for 848.5 times. Increases in public spending were generated by inflationary scale phenomena, but also by the interventionist side of the state in the economy (mainly financing social security and economic affaires) due to the transition to market economy.

Graph 1. Evolution of public expenditures as % of GDP in Romania during 1992-2010

Source: Developed by author, based on data available on the Ministry of Public Finance and National Institute of Statistics websites

In Romania, the share of total consolidated public expenditure of GDP was over 30%, with an increasing trend during 1994-1998, followed by a decrease between 2000 and 2004, followed by an upward trend, from 34.64 % in 2006 to 39.47% in 2010.

The intervention of public authorities, through budgetary and fiscal stimulus, aimed at redressing the Romanian economy has become a necessity since October 2008, as the negative effects of the economic crisis deepened.

Table 1. Evolution of public expenditures (selected ones from the economic classification) in Romania during 2006-2010 (million RON)

Indicator	2006	2007	2008	2009	2010
Staff expenditures	21,057	25,588.9	43,344.5	46,710.7	42,806.5
Interests	2,489.7	2,739.7	3,893.3	6,061.8	7,274
Capital expenditures	12,717	14,410.4	23,203.4	23,175.3	19,368.9
Social-assistance transfers	30,901.7	38,326.7	53,592.4	63,962.1	68,601.9
Goods and services	22,744.8	25,835.1	33,225.5	28,835	29,801.2

Source: Ministry of Public Finance, Executions of consolidated budgets between 2006 and 2010

Public expenditures have had an excessive dynamic, being above the level of available public resources and were oriented to unproductive activities in a rather high percentage (89%), increasing by 73.56% compared to 2006. As international financial institutions have warned at the end of 2008, Romania spends a lot on unproductive expenditures, such as budgetary employees' wages and pensions, and this must decline, in favor of investments which foster production, contributing to the country's economic recovery.

Social assistance transfers have doubled between 2006 and 2009, reaching 63,962.1 million RON in 2009, which represented 12.7% of GDP. In this period of recession, state social security budget expenditures increased as a result of social measures taken by the Romanian Government, consisting in: increasing the guaranteed minimum social pension to 350 RON (from October 1, 2009); increasing allowances for the children to 100 RON; extend the period of eligibility for unemployment benefit for a period equal to the institutional framework necessary to graduation, courses and retraining; indexing pensions by 3% from April 1, 2009 and 2% from 1 October 2009, even if this is not a measure strictly activated in the current crisis, but it better protects pensioners in the short term by maintaining their purchasing power, but at the same time, it contributes to long-term fiscal sustainability of the pension system etc. In 2010, compared with 2009, these expenditures also increased with 14.50%.

Expenditures on social assistance are justified during the economic crisis, given the double increase of the unemployment rate, from 4%, its value in October, 2008, to 7.8%, in December 2009, 8.2% in March, 2010 and then decreasing to 6.87% in December, 2010.

As in the pre-crisis period, it is found a link between unemployment insurance costs and business cycle. According to Ministry of Public Finance statistics, in 2009, year marked by the economic crisis, public expenditures for unemployment insurance doubled (reaching 2.7242 billion RON), compared with 2008 (1.3 billion RON), while

in 2010, expenditures exceeded the amount for 2009, recording 3.8 billion RON. In 2009 there were adopted Government decisions to support up to 50% of the services cost for organized training for a total of more than 20% of unemployed persons. The aim of these measures was to reduce the effects of financial and economic crisis on vulnerable social categories.

In the context of the crisis, in order to reduce the increasing number of unemployed and to restore those lost jobs, was adopted an Ordinance in February 2010, to reduce spending for the next period for all social budgets, following a decision of exemption for a period of 6 months the payment of social contributions for employers which employ for at least 1 year unemployed persons, being unemployed for at least 3 months. According to Government press releases, the total number of employees, as a result of GEO 13/2010, on December 2010 was 6,072 and the number of employers who have benefited of GEO 13/2010 was 3,625.

Solutions in order to stimulate job creation, to recognize the value of work must be found, because employment is the real way to economic improvement. In the category of active measures of employment programs we may include: job-matching services, information and counselling services, organizing vocational training courses, benefits granting to unemployed who take up employment before the end of the period of entitlement to the unemployment benefit, persons taking up employment through employer's subsidization etc.

Spending on pensions has also recorded increases from year to year, creating a budget deficit of €1.5 billion in 2009. In 2009, the Romanian state has spent 48 billion RON, representing 9.5% of GDP and 31% of the state revenues. For 2010, public pension costs were 42 billion RON, 8.33% of GDP. The Romanian Government decided in 2010 to reform the public pension system, which involves a review of a number of special pensions, except judges, according to the decision of the Constitutional Court, as well as raising the retirement age to 65 years for women and men, to eliminate all discrimination in the system, to reduce pensions set at a high level and also to

contribute to the unification of public pension system.

Another change in public expenditures concerned goods and services, which registered a decrease of 12.6% in 2009 compared to 2008, following the recovery measures approved by the Ordinance Emergency 34/2009 and an increase with 3.35% in 2010 compared with 2009.

Staff expenditures increased by 2.4% in 2009 (46,710.7 million RON in 2009, 9.2% of GDP) compared to 2008, mainly due to salary increases approved in the second half of 2008. In 2010, staff expenditures recorded, compared with 2009, a decrease of 9.75% in the general government budget, as wages were reduced by 25%.

In addition to these changes in public expenditures, the most important was contracting a stand-by arrangement with the IMF, European Commission, World Bank and other international financial institutions as a preventive measure in the current crisis and with an estimate for 2009 of economic decrease. This external loan generated an increase in the interests paid, with 55.69% in 2009 compared to 2008 and only with 19.98% in 2010 compared with 2009.

Although during the crisis, according to economic theory it is important to spend on investments, the Ministry of Finance statistics shows even a decrease in these expenses in 2009 compared with 2008 (with 13.3%), while the projection for 2009 was 7% of GDP and the execution shows 4.9% of GDP. In the category of investments in 2009 were included the first house program, which has increased the ceiling for government guarantees to 75,000 € for housing associations which are associated for housing (till February 2011, the total amount of government guarantees granted being 1,457.8 millions €); the national program of cars renewal (till December 2010 were allocated 722 millions RON for this program); state aid schemes to ensure sustainable economic development (the total budget for minimis schemes for 2008-2010 was €200.000).

3. Conclusions

If during '29-'33s, the philosophy of laissez-faire was replaced by the Keynesian doctrine, and '70s have placed the welfare state in a crisis of legitimacy, starting from 2008 we can talk of a resurgence of the Keynesian paradigm, according to which government intervention is seen as a way to stimulate the economic recovery.

I believe that the interventionist role of the state is important in the current context of the economic crisis as long as the economic and social measures it implements can lead to the recovery of the country, if small businesses are supported by state aid schemes and tax incentives, given their potential of creating new jobs, if through public expenditure are helped economic sectors hardly hit by the crisis etc.

For the next period are necessary reductions of unproductive expenditures, such as staff costs and increases of intellectual and economic investments in strategic areas, which can represent an exit from the economic crisis.

Changes in Social Protection Policies for Unemployed Promoted in Romania in the Context of the Economic Crisis

Sava Anca-Ştefania

„Alexandru Ioan Cuza” University OF Iaşi, Doctoral School of Economics

sava.anca@yahoo.com

Abstract

The aim of this paper is to address the changes in social protection policies for the unemployed, which were promoted in Romania in the context of the global crisis. Firstly, it presents a brief literature review on the role of implementing unemployment policies in times of recession, according to which unemployment insurance works as a built-in stabilizer for the economy. Secondly, the paper analyzes the evolution of the unemployment indicators (unemployment rate, public expenditures on unemployment insurance etc.) for Romania in the recent years. Also, it presents the active and pasive measures implemented by the Romanian Government as a response to the negative effects of the economic crisis. The study shows that there must be found solutions to stimulate job creation and to recognize the value of work.

Key words: unemployment insurance, economic crisis, public expenditures, social protection

J.E.L. Classification: J65, E32, H50, H55

1. Literature review on the role of implementing unemployment policies in times of economic recession

Robert Shimer, an Economics professor at the University of Chicago said that “even in a depressed economy, more generous unemployment benefits tend to raise the unemployment rate. Benefits are obviously good for the unemployed, but there are some clear tradeoffs.”

According to Orszag [1, p.1], unemployment insurance is a particularly effective stimulus which helps to break the

negative cycle of increasing unemployment, because by partially compensating for lost income, it lessens the reduction in spending that unemployment can cause.

Stiglitz [2, p. B01] said that “if we give money to people who have lost their jobs in this recession, it would be quickly spent”, based on the idea that unemployed spend much of any additional income that they receive during unemployment.

There are studies which quantify the contribution of unemployment insurance to reducing the negative effects of the economic recession. Auerbach and Feenberg [3] in a study on the USA data show that the unemployment insurance system is at least eight times more efficient than the tax system to offset the impact of a recession, as offers about 25% of the total impact of automatic stabilizers, taking into account that unemployment insurance are 1.5-3% of the total size of the federal revenues.

Another study conducted in Canada, by Stokes [4], demonstrated the stabilizing impact of unemployment insurance program on GDP, as it increased employment during the 1981-1982 and 1990-1991 recessions and reduced it during the boom of the second half of the 1980's. These countercyclical effects also contributed to a rise in participation rates, thereby reducing the stabilizing impact on the unemployment rate. The unemployment insurance program's impact on other economic indicators was similar to that on employment and GDP. The average reductions in the GDP gaps in the 1980's were approximately 8, 11, and 4 per cent for the 1981-1985, 1987-1990, and 1991-1993 periods. In the 1978-1980 periods, the unemployment insurance program increased the GDP gap by almost 2 percentage points [4, p.37].

Boeri [5] using series data for 1980-2002, for USA, shows that the introduction of unemployment benefits is associated with

about 1-2 percentage point increases in the yearly rate of job destruction and with a 2.5-3 percentage point increases in job turnover. This implies a positive effect on job creation as well, but this effect was not found to be statistically significant when estimated separately.

Peter A. Diamond, Dale T. Mortensen and Christopher A. Pissarides were awarded the 2010 Nobel Prize in Economics for their analysis of markets with search frictions, where buyers and sellers have difficulty finding each other. They found the answer to why it takes so long for people to find jobs, even in good economic times, and why so many people can be unemployed even when many jobs are available. Since people are not identical and neither are jobs, it takes time for unemployed workers to be matched with the proper job.

A graphical representation of the relationship between unemployment and the job vacancy rate is the Beveridge curve, which explains the inefficiency of labor markets due to mismatches between available jobs, the unemployed and an immobile labor force. The equilibrium on labor market between the job vacancy rate (the number of unfilled jobs expressed as a proportion of the labor force) and the unemployment rate is set at higher or lower levels on the Beveridge curve, depending on the status of the business cycle. For example, during recessionary periods (corresponding to a position on the lower side of the 45 degree line), the number of vacancies decreases, the unemployment rate increases, so the equilibrium in the labor market moves downward along the curve, while during expansionary periods (above the 45 degree line), the number of vacancies increases due to expansion of production capacities of firms and thus, the unemployment rate is at a lower level.

According to an article written by economists in the Research Department of the Federal Reserve Bank of Cleveland [6], a structural change might move the economy to equilibrium on a different Beveridge curve. An example might be fundamental technological change which creates a gap between the skills needed for open vacancies and the skill set of the unemployed. In this case, for the same level of job openings, equilibrium unemployment will be higher,

illustrated by the Beveridge curve shifting up and to the right.

Another article written by Nickell et al. [7] explains the movements in the Beveridge curves for some OECD countries, from the 1960s to the 1990s, by changes in labor market institutions which are important for search and matching efficiency. The variables considered were the benefit system, the system wage determination, employment protection, labor taxes and barriers to labor mobility [7, p.9]. The unemployment benefit system through the level of benefits, the duration of entitlement, the coverage of the system influence the equilibrium unemployment.

Mortensen [8, p.510] presents two possible offsetting incentive effects. The first effect dominates if the worker is near the end of the benefit period and also operates in the case of an unqualified unemployed worker. According to this effect, an increase in the benefit rate stimulates the demand for leisure as a consequence if and only if income and leisure are complements in household production. Secondly, the same increase in the benefit rate or in the maximum benefit period induces an increase in the indirect utility of being laid off in the future as well as the indirect utility of remaining unemployed during a current spell in the case of a qualified worker.

2. Analysis of Romanian unemployment indicators

According to National Agency for Employment Statistics, the number of registered unemployed registered a decline with 53.24%, from December 2001 (826,932 unemployed) to December 2007 (386,667 unemployed), as a result of improved economic situation of Romania. As the financial crisis has deepened since the end of 2008, the number of unemployed doubled, reaching 709,383 persons at the end of December 2009. Also, in 2010, the number of unemployed increased from 740,982 persons in January 2010 to 765,000 persons in March 2010, followed by a decline to 645,500 people registered in October 2010, due to Government measures.

The unemployment rate, an indicator calculated by comparing the total number of unemployed to active civilian population on 1 January, was correlated with business cycle developments. Thus, from 2001 to 2008, gross domestic product evolution has been a positive one, the absolute amounts increased from 116.7 billion RON to 503.9 billion RON, while for the unemployment rate has been a downward trend, its values decreasing significantly from 8.8% in 2001 to 4.3% in 2007.

Figure 1. Evolution of the unemployment rate during 2001-2010 (%)

Note: 2001-2010: data for December
Source: National Agency for Employment.

As the economic crisis has deepened since the end of 2008, businesses have been severely affected by lack of credit, and this was felt on the employment and on the evolution of gross domestic product. The registered unemployment rate in late December 2008, at the national level was 4.4%, 0.3 pp higher compared with December 2007 and doubled till the end of 2009, reaching 7.8%, while gross domestic product decreased to 491.3 billion RON. During 2010, as the number of unemployed has increased, the unemployment rate exceeded 8%. In these circumstances, additional expenses to pay state unemployment benefits were needed. As a result of measures approved by the Government, the unemployment rate fell in 2010, reaching 6.9% at the end of December.

During recessions, when unemployment rate is rising, unemployment insurance expenditures increase and revenues decrease, while during boom periods, when unemployment is falling, expenditures decrease and revenues will rise as employment rises.

Table 1. Evolution of public expenditures and revenues of the unemployment insurance budget (2004-2010)

Year	Expenditures	Revenues
2004	1,658.29	1,903.51
2005	1,535.10	2,186.06
2006	1,570.80	2,271.00
2007	1,407.90	2,472.10
2008	1,355	1,963.50
2009	2,724.20	1,482.70
2010	3,821.8	1,320.1

Source: According to data provided by Ministry of Public Finance for 2004-2010

Between 2004 and 2008, expenditures for unemployment insurance decreased from year to year, being below the state revenues from unemployment insurance contributions. Their share in gross domestic product registered a downward trend from 0.69% in 2004, to 0.24% in 2008. In 2009 and 2010, following an increase in the number of unemployed and higher rates of unemployment, due to the economic crisis, unemployment benefit payment costs have doubled compared with 2008, reaching almost 0.74% of gross domestic product.

3. Analysis of the Program for Employment measures during the economic and financial crisis (2008-2010)

In the category of active measures of the Program for Employment were included: job-matching services, information and counselling services, employment through organizing vocational training courses, benefits granting to the unemployed who take up employment before the end of the period of entitlement to the unemployment benefit, incentives for employers for the employment of certain categories of disadvantaged persons in the labor market etc.

The number of employees through the implementation of the Program for Employment in 2010 was 377,772 persons, compared with 304,588 persons in 2009.

In the pre-crisis and also in the crisis period, the active measure with the biggest share in the total employed was job-matching

services. In 2008, its share represented 77.63% of total employment measures. Even in 2010, this measure represented 80.78% of the total employed.

A second measure is information and counselling services, which accounted in 2008 for 16.04% of total employed, with 3.64 points higher than in 2007. Regions with the highest share in total were in 2008 North-West (23.15%), Central (18.58%), Northeast (17.43%) and Bucharest-Ilfov region with the lowest value, respectively 0.55%. In 2010, information and counselling services have held a share of 17.15% of total persons employed, compared with 17.62% during the same period in 2009.

Employment through professional training is an active measure which held in 2008, at national level, 4.74% of total measures. In 2010, at national level, the percentage was 4.45% of total employed, compared with 5% as it was in 2009.

Among the program's active employment measures which had a lower share in total measures were included those to stimulate the employers for the employment of certain categories of disadvantaged persons in the labor market. A first measure implemented in 2008 which can contribute directly and quickly to provide jobs in rural areas and in those most affected by unemployment was to subsidize employers on labor costs in temporary employment programs for development of local communities. This measure has contributed to employment at a rate of 8.55% in all measures compared with 10.45% in 2007. In 2010, this measure represented 3.66%, compared with 7.22 in 2009.

Another measure applied in 2010 was the creation of jobs through the employment of unemployed over 45 years old single providers for the monoparental family, a measure which represented 3.77% of total employment program, compared with 1.56% in 2009.

Jobs subsidies through employment of the unemployed who are 3 years away from reaching the statutory retirement conditions were measures applied during the crisis and the result consisted in employment of 350 persons (0.08% of the program) in 2008 and 207 persons in 2010 (0.05% of the program, compared with 0.02% in 2009).

Subsidizing labor costs in temporary employment programs for the development of local communities was a measure applied in 2010, with a low proportion of 3.66%, compared with 7.22% in 2009.

Subsidizing jobs through employment of graduates of educational institutions represented 2.6% of the program in 2008. In 2010, 1.47% graduates of educational institutions were employed in the program by providing this type of grant, compared with 1.18% in 2009. Graduates employed through this measure in 2008, as in 2009 and 2010, were mostly university graduates, followed by upper secondary or post secondary education and the schools of arts and crafts.

Subsidized employment through the employment of people with disabilities represented a type of of subsidy with a share of 0.07% in 2008, compared to 0.06% in 2007 and 0.06% in 2010, compared with 0.03% in 2009.

Stimulation of job-matching is another measure that supports people seeking employment. In 2010, of 3,410 persons employed by the mobility bonuses, a percentage of 45.66% were employed in a more remote town situated 50 km from their permanent residence and 54.34% have changed their residence due to employment.

The Program for Employment included advice and assistance services for starting a new business, with a share of 0.13% of total employment measures, in 2010, compared with 0.29% in 2009.

In 2010, has already been applied a measure of employment through solidarity contracts, under Law no.116/2002, a lower share of 0.22% of total employment measures, compared with 0.23% in 2009.

As the financial crisis entered in a phase marked by serious problems since October, 2008, the Romanian government priorities were job creation and helping those who have been hurt by the economic downturn.

In 2009 there were adopted Government decisions to support up to 50% of the services cost for organized training for a total of more than 20% of unemployed persons. The aim of these measures was to reduce the effects of financial and economic crisis on vulnerable social categories.

Also, in the context of the crisis, in order to reduce the increasing number of unemployed and to restore those lost jobs,

was adopted an Government Ordinance (no.13/2010) in February 2010, to reduce spending for all social budgets, following a decision of exemption for a period of 6 months the payment of social contributions for employers which employ for at least 1 year unemployed persons, being unemployed for at least 3 months. The total number of employed, at the end of December 2010, was 6,072 persons.

4. Conclusions

The macroeconomic literature shows that the unemployment insurance program alone provides significant relief to the newly unemployed and that it accounts for a large and important countercyclical force to prevent job losses.

We have to take into account the fact that business cycles are a normal feature of our economy and that the private sector, alone, cannot provide exactly the right supply of jobs all through thick and thin market conditions. It is also important to mention that the performance of an unemployment insurance program depends not only on unemployment insurance structure, but also on specific factors of a particular country.

In times of recession, public authority intervention through fiscal-budgetary measures is a necessary one, in order to help reducing the unemployment rate and create new jobs.

By providing protection against unemployment, unemployment insurance program increases the security among employees and provides financial compensation to those who have lost their jobs.

The Tourist Services Market in Romania

Savu Cosmina Silviana
„Spiru Haret” University
cosmina.savu@yahoo.com

Abstract

Tourism is an important branch of the global economy and also an important employer.

In the last decade we have witnessed a diminishing demand for domestic tourist services due, on the one hand, to the low quality of the services comparing to the ones offered by other countries and on the other hand to the prohibitive prices. The present paper attempts to present the situation of the Romanian tourist services in terms of supply and demand and also in comparison to the foreign market competition.

Key words: tourist market, promotion, tourist services

J.E.L Classification: L83

1. A SWOT analysis of the Romanian tourism

Following a SWOT analysis of the present situation we have come to the conclusion that the difficulties that the domestic tourism is confronted with are caused by the decrease of the population's purchasing power on the background of the diversification and accessibility of foreign offers.

Romania is a beautiful country, represented by the extraordinary natural sceneries: mountains, lakes, (e.g. the Cobilita Lake in the Calimani Mountains, which is a reservoir lake, the Iezer Lake in the Rodna Mountains, a glacial lake, The Saint Ann Lake in the Ciuc Mountains which is a volcanic lake, etc.), rivers, forests (Romania occupies the thirteenth place in Europe in the ranking of forested surfaces, outnumbering Germany and The Czech Republic by 0.33 hectares per capita.). As we can notice, there is a diversity of sceneries to be exploited by the Romanian tourism but we do not value

and take maximum advantage of this as other countries do of their natural beauties.

From the cultural point of view tourism is also quite diverse; one can visit historical museums, cultural establishments, byzantine monasteries, castles, traditional peasant houses (The Romanian Athenaeum, The Arch of Triumph, The National Theatre, The Botanical Garden, The National History Museum, The "Grigore Antipa" National Museum of Natural History, The Village Museum, the "Romulus Cioflec" Memorial House, The "Danube Delta" Ecotourist Centre, The Bran Castle, etc.).

The people's hospitality, their traditions impress thousands of tourists every year, the fresh year, the traditional food specialties, the Romanian folklore, the traditional dances as well as the winter sports, the ATV, scooter and carriage rides, fishing, mountain climbing are all attractive for adventure seekers. In order to facilitate the tourists' access to their destinations motorways and airports with accessible prices have been built and buses have been introduced for less accessible routes.

In the case of all countries we can find weak points as well, for the tourist services. For example the lack of communication between tourist agencies and hotel representatives may lead to unpleasant situations such as bookings which are not made in due time, or bookings that do not correspond to the tourist's requirements. Acid rains, snows, land slides have sometimes damaged the European roads on Romania's territory. The lack of road signs has made many tourists choose railway transport which is often subject to delays.

If people were more united, historical monuments and also the environment could be better preserved. The lack of skilled staff is also a big problem that hotels are confronted with as the low quality of services is often generated by this very reason. Sometimes the accommodation standards of a

Romanian three stars hotel can hardly reach the standard of a one star hotel from other countries.

That is why, due to its strengths which oppose the weaknesses, the Romanian tourism has become very expensive thanks to its superbe destinations but with a very low quality of services.

We believe that there is a series of opportunities which could support the future development of the domestic tourism. Resorts should benefit from investments and county roads should be renewed in order to facilitate tourists' access to the extraordinary destinations waiting for them. Certain less known but really impressive parts of the country should be advertised as they are worth visiting, tourist information centres can be opened so that visiting opportunities can be advertised for each region of the country and even for the whole country. A wider range of Romanian products, a differentiated offer for age and preference categories as well as a better quality-price ratio would offer an advantage to our country in comparison to other countries.

Those in charge with the Romanian tourism should not forget about the qualitative criteria of the hotel services such as: perfect cleanliness (in the parking place, in front of the hotel and inside it, etc), food adapted to the clients' preferences (Swedish bufet or a la carte, etc), entertainment facilities (swimming pool, jacuzzi, garden, sauna, billiards), the purpose of all these being to create customer loyalty.

The threats that the Romanian tourism is confronted with are generated by the effects of the economic crisis which have become more and more present; both supply and demand have started to fall since the summer of 2008 and the tendency accentuated in 2009. The diminishing purchasing power is not only an effect of the crisis but also of other phenomena such as strong viruses, fires, tornadoes which have led to the closing of certain tourist areas. This meant a decrease by 4% of the tourist industry at a global level, the Tourist World Organization estimated. Poor offers are also another weakness and so are the high prices comparing to the low quality and services, a situation which does not characterize other countries.

2. Romania's tourist opportunities

Romania offers different types of tourism, for everyone's needs. The most widely practised is the tourism for resting and relaxation which offers wonderful resorts for unforgettable holidays on the seaside of the Black Sea and on the Prahova Valley, in Maramures, Ocna Sugatag, Sovata, for practising winter sports as well as the tourism for health purposes which benefits from special resorts that offer spa treatment, etc. Week-end tourism offers a lot of entertainment as tourists want to visit many tourist objectives in a short time. "Sustainable tourism was conceived in order to better manage all the resources so that the economic, social and aesthetic needs should be satisfied while maintaining cultural integrity, essential ecological processes, biologic diversity, life preserving systems". (The Tourism World Organization) The ecological tourism is that type of tourism which is practised in protected, wild areas. The educational tourism has started to develop as well, for example due to the people who wish to learn how to ski. Sport tourism supports the people's participation in certain world sport events with offers at reasonable prices. The packages include the ticket for the sports event (e.g. the Football World Cup), the flight, the accommodation, etc.

The number of locations increased from 2007 to 2009 by 401 accomodation establishments of different types: hotels, motels, etc and so did the accomodation capacity, from 283701 places in 2008 to 303486 in 2009, according to the Tourist Statistical Abstract 2010.

Establishments of tourists reception with functions of tourists accommodation and the tourists accommodation capacity, by type of establishments			
Number of establishments			
	2007	2008	2009
Total	4694	4841	5095
Hotels	1081	1111	1170
Motels	150	153	146
Tourist inns	6	5	5
Hostels	79	81	97
Tourist villas	708	718	747
Bungalows	266	264	265
Tourist chalets	108	116	123
Holiday villages	3	3	4
Camping sites	62	59	55
School and pre – school camps	115	111	111
Tourist halting places	30	31	30
Tourist boarding houses	736	783	878
Agro –tourist boarding houses	1292	1348	1412
Houselet – type units	49	50	46
Ship accommodation places	9	7	6
Source: National Institute of Statistics: Romanian Tourism – Statistical Abstract 2010			

According to the tour operator agencies the number of foreign tourists having visited Romania in 2008 was of 148663 and in 2009 of 172260 which means a significant increase while the number of Romanian tourists having spent their holidays abroad was of

712031 in 2008 and of only 334001 in 2009 which means a decrease by almost a half.

Number of tourists taking part in the tourist actions organized by travel agencies						
	Incoming activity		Activity of domestic tourism		Outgoing activity	
	2008	2009	2008	2009	2008	2009
Tour operator agencies Total number of tourists	148663	172260	416541	129990	712031	334001
Agencies with sale activity Total number of tourists	8526	6210	21103	98076	27744	129174
Source: National Institute of Statistics: Romanian Tourism – Statistical Abstract 2010						

From the statistic analyses we notice that in 2009 the outgoing activity of the agencies is 2,57 bigger than the intern tourism, beware of the 2008 when the value of this activities were 70% superior from the national tourism results.

Since 2007 until the present the most widely used transport by foreign tourists has been the road transport, followed by the air transport and the railway one; the same means of transport are preferred by the Romanians who visit other countries according to the Statistical Abstract 2010.

The purpose of the European tourist integration is the development of tourism paralleled by environment protection, the increase of service quality, customs control improvement, etc.

Rural areas are progressively turned into tourist destinations with the purpose to attract tourists. From TWO research it becomes obvious that rural tourism is developing much faster than international tourism.

The process of integration should develop based on certain market laws such as the tourist service promotion and its development according to the market needs,

the professional specialization of tourism workers or the use of differentiated offers in order to satisfy the tourists' needs.

Internet advertising strategies

Romanian tourist agencies have noticed that the majority of people search information on the tourist offers on the internet, that is why tourist agencies advertise their offers on the internet. Some agencies have web sites in Romanian, others in Romanian and English (www.eturism.ro, www.infotravelromania.ro, www.infoturism.ro, www.romaniatour.ro, www.romaniatravel.ro), by domains: seaside, mountains, international offers, low cost offers, last minute offers, early booking offers, etc.

Advertising tourist offers on the internet has many advantages as one can check the newly introduced offers anytime and anywhere, as well as their complexity, the details regarding the price, the facilities and bonuses offered, etc.

3. Conclusion

We recommend the use of recession tourism which is an appropriate choice in the context of the global economic crisis as it is characterized by low cost – and therefore very successful – prices.

The Romanian tourism has come to be unattractive for both Romanian and foreign tourists because of the high prices and the low quality that characterize it; tourists have discovered that they can benefit from excellent services at similar prices in countries such as Turkey, Greece, Austria, Germany, etc.

Due to a relatively large share of the population with low incomes in the past few years has declined the domestic tourism, so if charges would be a little more low and the conditions more quality, Romanian tourist would prefer a domestic location than an international one.

In this respect, we encourage recession tourism, which is due to the global economic crisis and is defined by low prices offered to customers.

We believe that a recovery of the Romanian tourism should be based on the modernization of the tourist products, of resorts and tourist routes, both the well known and the less known ones so that Romania could become a favourite destination due to tourist services at European standards. Domestic tourism has also been characterized by a decline in the recent years because of a significant percentage of population with low incomes but if domestic prices were slightly lower Romanian tourists would prefer domestic destinations rather than foreign ones.

Accounting and Fiscal Treatment of Price Discounts

Sălceanu Alexandru
"Oil and Gas" University of Ploiești
www.upg-ploiesti.ro

Abstract

The trade and financial discounts are offered the clients by the suppliers, under the form of a percentage on the selling price, being described in detail in the contracts concluded between the parties. According to the provisions of OMFP no. 3055/2009, these discounts influence the turnover. They must be listed separately in the profit and loss account. If the value of the fungible supplies which are in the administration after the methods FIFO, CMP and LIFO have been applied differ significantly at the date of the balance sheet from the value determined on the basis of the latest market value known before the date of the balance sheet, then the value of this difference must be shown in the explanatory notes, on the total amount and on categories.

Key words: sales promotion, trade discounts, financial discounts, income from discounts, expenses regarding discounts.

J.E.L. classification: E 62, H 32, M 41.

1. Introduction

No one has doubts today regarding the necessity to promote the products as a basic condition which decisively contributes to speeding up sales and consequently increasing profit. One of the methods used in order to promote products is offering discounts, a method meant to repay the client's loyalty, paying the debt before due date, buying a large amount of goods, all of these contributing substantially to increasing the turnover.

2. Accounting regulations regarding discount purchases and sales

In the selling-buying relations, there may occur discounts offered by the seller to the buyer. In this respect, OMFP no.3055/2009 for approving of the Accounting Regulations as per the European directives stipulates the following differences (p.51, par.4) [1]:

'a) reductions are accepted for defects of quality and are applied on the selling price; b) abatements are accepted in the case of sales being higher than the established volume or if the buyer has a preferential status; and c) rebates – price reductions calculated on the whole of the transactions made with the same party during a limited period of time (p. 51, par. 5).'

Apart from these, the clients may be offered financial discounts, which are "under the form of settlement discounts offered for paying the debts before the normal maturity date (p.51, par. 6)''

Both the trade and financial discounts are offered the clients by the suppliers, under the form of a percentage on the selling price, being described in detail in the contracts concluded between the parties, where certain conditions that must be fulfilled are stipulated (the quantity provided, invoicing date, delivery date, payment date).

As for the discount accounts, there are mentioned the following differences in OMFP no.3055/2009 [1]:

-The trade discounts received or offered after the invoicing, irrespective of the period they cover, are shown separately in accounting (account 609 'Received trade discounts', and account 709 'Offered trade discounts' respectively), on the basis of the accounts of the parties (p. 51, par. 4);

-The financial discounts, received by the buyer from the supplier, represent income of the period, irrespective of the period they

cover (account 767 'Income from received discounts') For the supplier, these offered discounts represent expenses of the period, irrespective of the period they cover (account 667 'Income from received discounts') p. 51 (6).

Example no. 1 (Trade discounts offered before invoicing under the form of an abatement)

The limited liability company 'Alfa' purchases 50 m³ of fir timber for an acquisition price of 500 lei/m³ from the 'Beta' LLC. As per the provisions stipulated in the contract, when an acquisition exceeds the quantity of 30 m³, the supplier will offer the buyer a discount of 10%.

Note: As per the provisions of art. 137 par. 3, letter a) in the Fiscal Code, *'the abatements are not included into the taxation system of the added value tax if they are offered by the supplier directly for the benefit of the client at the moment of the delivery and do not actually represent payment of a service or of a delivery'*. [2]

In accounting, the following are recorded:

For the buyer:

- the value of the raw materials that are bought 50 m³ x 500 lei/m³ = 25.000 lei
- the discount offered 25.000x10%=2.500
- the net value

Buying the raw materials:

	%	=	401		<u>27.900</u>
				'Suppliers'	22.500

'Raw materials'					5.400
4426					
'VAT input tax'					

For the seller:

Income resulted from selling the finished products

	%	=	%		<u>27.900</u>
				'Clients'	22.500

'Income resulted from selling the finished products'					5.400
4427					
'VAT output tax'					

Example no. 2 (Trade discounts offered after invoicing under the form of rebates)

The limited liability company 'Gama' bought from 'Beta' LLC in February, fiscal year N, raw materials on several occasions amounting to 5.000 lei, total selling price, VAT 24%. In the contract concluded between the seller and the buyer, a discount under the form of rebates of 5% is stipulated, provided that the total value exceeds 4.000 lei. Accordingly, the discount amounts to 250 lei (5.000 x 5%)

In accounting, the following are recorded:

For the buyer, receiving the discount					
	401	=	%		310
				'Suppliers'	250

'Received trade discounts'					60
4426					
'VAT input tax'					

For the buyer, offering the discount

	%	=	4111		310
				'Clients'	250

'Offered trade discounts'					60
4427					
'VAT output tax'					

Note: According to the provisions of OMFP nr.1752/2005, the discounts offered in subsequent invoices decrease the turnover directly, and according to the provisions of OMFP nr.3055/2009, they have the same effect on the turnover, with the observation that these discounts will be shown separately in the profit and loss account.

Another note: The accounting treatment of these trade discounts contradicts the **matching principle** as the discount invoices are offered for sales recorded in previous fiscal years, because for the seller there will occur a decrease of the turnover in the current fiscal year for discounts that apply to previous fiscal years, whereas for the buyer there will occur a decrease of the expenses in the fiscal year in which the discount invoice is received, even if the acquired assets did not affect the profit and loss account in the previous fiscal years.

Example no. 3 (Financial reductions under the form of discounts)

The joint stock company 'Gama' sells to 'Minerva' LLC finished products amounting to 50.000 lei, total selling price, VAT 24%, with a settlement date of 2 months, according to the contract. As the debt was paid before the date stipulated in the contract, the seller offers the buyer a reduction (discount) of 3% for which there will be drawn up a discount invoice.

In accounting, the following are recorded:

1)For the seller:

a)The selling invoice for the finished products amounting to 50.000 lei, VAT 24%

4111	=	%	<u>62.000</u>
'Clients'	701		50.000
		'Income resulted from selling the finished products'	
	4427		12.000
		'VAT output tax'	

b) The invoice for the reduction offered under the form of a discount for the payment before the due date, which levels the taxation basis of VAT, amounting to 1.500 lei (50.000 x 3%)

%	=	4111	<u>1.860</u>
667		'Clients'	1.500
		'Expenses regarding the discounts offered'	
	4427		360
		'VAT output tax'	

2)For the buyer

a)The invoice for the purchase of raw materials

%	=	401	62.000
301		'Suppliers'	50.000
		'Raw materials'	
	4426		12.000
		'VAT input tax'	

b)The invoice for the reduction received, which levels the taxation basis of VAT, amounting to 1.500 lei (50.000 x 3%)

401	=	%	1.860
'Suppliers'	767		1.500
		'Income from discounts received'	
	4426		360
		'VAT input tax'	

Example no.4 (Trade and financial reductions)

The limited liability company MINERVA, having merchandise trade as its main object of activity, recorded in administration an amount of 50 chairs evaluated at a unit cost of 30 lei/piece on February 1st 2011.

In February, the following were recorded:

a)buying 100 chairs at a unit cost of 36 lei/piece, discount 10%, VAT 24%, according to the invoice on February 5th .

The total cost of the acquisition is first calculated considering the 10% discount offered, which levels the acquisition cost in the sense that it reduces it.

Total acquisition cost = 100 buc x 36 lei/buc = 3.600 lei

Adjusted acquisition cost = 3.600 – 360 = 3.240 lei

%	=	401	4.017,6
371		'Suppliers'	3.240

'Merchandise'

4426 777,6

'VAT input tax'

b)buying 150 chairs evaluated at a unit cost of 45 lei/piece, VAT 24%, according to the invoice on February 7th 2011 .

%	=	401	8.370
371		'Suppliers'	6.750

'Merchandise'

4426 1.620

'VAT input tax'

c)Selling 175 chairs at a unit selling price of 60 lei/piece, VAT 24%, with an abatement of 5% and a settlement discount of 2%, according to the invoice on February 11th 2011.

Table nr.1. - Preliminary calculations

No	Explanations	Value (lei)
1	Total selling price 175 pieces x 60lei/ piece	10.500,00
2	Abatement value 5% (rd1 x 5%)	525,00
3	Net trade value (rd1-r2)	9.975,00
4	Discount value 2% (rd3 x 2%)	199,50
5	Net financial value (rd3 – rd4)	9.775,50
6	VAT 24% (rd5 x 24%)	2.346,12
7	Net value to be charged (rd.5+ rd.6)	12.121,62

This complex operation is detailed as follows:

c1) The income that is to be charged from the client, amounting to the net trade value of 9.975 lei, VAT 24%.

4111	= %	12.369
'Clients'	707	9.975
	'Income from selling the merchandise'	
4427		2.394
	'VAT output tax'	

c2) The discount offered by the client, amounting to 199,50 lei (9.975 x 2%), TVA 24%.

%	=	4111	247,38
667		'Clients'	199,50
		'Expenses regarding the discounts offered'	
4427			47,88
		'VAT output tax'	

Under these circumstances, the debt to the client amounts to 12.121,62 lei (12.369 – 247,38), as can be seen from the above-mentioned preliminary calculations.

c3) Writing off the sold merchandise, using the LIFO method (see the page in the Merchandise Ledger)

Cost of sold merchandise

150 pieces x 45 lei/piece	=	6.750 lei
25 pieces x 32,4 lei/piece	=	810 lei
Total 175 :		7.560 lei
607	=	371 7.560
'Expenses with the merchandise'		'Merchandise'

d) Receiving a discount of 20% for the acquisition made on February 7th, amounting to 1.350 lei (6.750 x 20%)

401	= %	1.674
'Suppliers'	609	1.350
	'Received trade discounts'	
4426		324
	'VAT input tax'	

e) Buying 75 chairs at a unit cost of 60 lei/piece, VAT 24%, according to the invoice on February 23rd 2011, with a settlement

discount of 5%, amounting to 225 lei (4.500 x 5%)

%	=	401	5.580
371		'Suppliers'	4.500
		'Merchandise'	
4426			1.080
		'VAT input tax'	
401	= %		279
'Suppliers'	767		225
		'Income from discounts received'	
4426			54
		'VAT input tax'	

f) selling 150 chairs at a selling unit cost of 75 lei/piece, according to the invoice on February 27th 2011 .

f1) Due income at a total selling price of 11.250 lei, TVA 24%

4111	= %	13.950
'Clients'	707	11.250
		'Income from selling the merchandise'
4427		2.700
		'VAT output tax'

f2) Writing off at production cost by applying the LIFO method

75 pieces x 60 lei/piece	=	4.500 lei
75 pieces x 32,4 lei/ piece	=	2.430 lei
TOTAL		6.930 lei

607	=	371	6.930
'Expenses with the merchandise'		'Merchandise'	

g) Offering a rebate of 10% to the client for the sale made on February 27th 2011, amounting to 1.125 lei (11.250 x 10%)

%	=	4111	1.395
709		'Clients'	1.125
		'Trade discounts offered to clients'	
4427			270
		'VAT output tax'	

In the profit and loss account the information is centralized as follows:

Table nr.2. Profit and loss account

No	Explanations	Value (lei)
1	Operating income	
2	Net turnover	20.100
3	Income from selling the merchandise (account 707)	21.225

4	Offered trade discounts (account 709)	1.125
5	Financial income	
6	Income from received discounts (account 767)	225
7	Operating expenses	
8	Expenses with the merchandise (account 607)	14.490
9	Received trade discounts (account 609)	1.350
10	TOTAL OPERATING EXPENSES	13.140
11	Financial expenses	
12	Expenses with the offered discounts (account 667)	1.995

The trade margin is calculated like this:

Trade margin = Net turnover – Total operating expenses

$$20.100 - 13.140 = 6.960$$

If the value shown in the balance sheet, resulted after the application of the FIFO, CMP and LIFO methods differ significantly at the date

If the value shown in the balance sheet, resulted after the application of the FIFO, CMP and LIFO methods differ significantly at the date of the balance sheet from the value determined on the basis of the latest market value known before the date of the balance sheet, then the value of this difference must be shown in the explanatory notes, on the total amount and on categories of fungible assets.

If the discounts are offered or received at the beginning of the fiscal year, for the transactions made in the previous year regarding compliance with the matching principle (OMFP nr.3055/2009, art.42), the trade reductions will be shown like this:

- in the income accounts and debts for which the invoice was not drawn up (418 'Clients – invoices to draw up');
- in the expenses or goods accounts, the debts for which the invoice was not received (408 'Suppliers –invoices not received).

In all cases, all the operations regarding these accounts are performed taking into account the papers that certify goods and service delivery (for example waybills, work report etc).

'If the discount value differs from the initial estimation, the difference will be registered in the expenses afferent to the previous year (if the invoice is received by the time the financial reporting is delivered) or in the expenses afferent to the current year, the result reported, function of the accounting policy of every company.' (Terçu A., 2010).[3]

When the invoice is issued or received, account 418 " Clients- invoices to draw up" will close by the account 4111 'Clients', whereas account 408 'Suppliers – invoices not received' will close by account 401 'Suppliers'.

3. Conclusions

The trade and financial discounts offered or received according to the provisions of the contracts concluded between the buyer and the seller affect expenses, income, the VAT taxation basis and consequently the corporate tax.

In order to apply a correct accounting treatment, when registering these discounts, one must take into account the provisions of OMFP nr.3055/2009, which, apart from the accounts already in use, also introduced account 609 'Received trade discounts' and 709 'Offered trade discounts'.

This way, accounting complies with the fiscal interest of the enterprise.

Abstract

The tourism and travel industry represents, worldwide, the most dynamic sector of activity and, at the same time, the most important workplace generator, as well as a source of recovering the national economies. Tourism is a complex activity because it generates the circulation of massive sums of money, thus contributing to the development of various economic activities which are favourable to the environment protection and to the globalization process emphasis.

Tourism itself cannot be considered as a "good" or "bad" action, nor as a "positive" or "negative" one, but its very diverse consequences can be evaluated in this manner. In the process of sustainable development of tourism, it is necessary that an increased attention be paid to the quality of the touristic products, which should simultaneously offer "the taste of perfection" and "the perfection of taste".

Key words: touristic destination, sustainable development, touristic potential.

J.E.L. classification: M21

1. Introduction

According to the unanimous acceptance, the tourism economic potential is impressing and the benefits which can be generated by a sustainable development cannot miss from any elementary calculation of a marketing planning which can minimize them, considering that tourism, a very strong

instrument of development, possesses a natural synergy with the sustainable development concept.

Any research related to the tourism from a certain territory has to take into consideration the phenomenon of the markets' interdependencies. This phenomenon presupposes that no touristic market can be judged independently, without establishing connections with the other markets. The touristic research is under a permanent pressure, on the one hand because of the competition, on the other because of some circumstantial factors, with an economical character, but also extra-economical (inflation phenomena, of economic, political and geostrategic circumstance).

The economical, social, political context from Romania after 1990 has not contributed to the development of the Romanian touristic sector. Moreover, according to the conclusions of the specialists, the effects of the transition to the market economy have determined a decline in tourism, together with other sectors of the economy. Thus, the international tourism demand has registered a decreasing trend because of multiple causes, such as: the low-quality level of the offered touristic services, the lack of diversity in the touristic programs, the reduced possibilities of recreation, etc.

2. Categories of the touristic destinations

Presently, the Romanian tourism is in a period of analysis and profound changes, which is motivated by the preoccupation of

being competitive on the unique European market.

With the intention of increasing the quality of the tourism activity, the policies as well as the strategic objectives which will be adopted have to aim at the following:

- The continuous achievement of a touristic product of superior quality, which corresponds to the modern tourism objectives;

- The improvement in the activity of the tourism personnel and in the quality of the touristic services;

- The diversification of the leisure offer;

- Encouraging the Romanian and foreign investments in the tourism activity;

- Elaborating more aggressive marketing policies which would aim at creating a positive image of the country outside the borders of Romania;

- Promoting a competitive Romanian tourism, comparative with the countries which have a developed tourism (Spain, France, Switzerland, etc.).

Romania occupies the 76th position out of 124, in the first world classification of tourism and travels, with a mark of 3.91 from a total of 7, between Azerbaijan and El Salvador, according to a classification made by World Economic Forum, which measures the tourism development potential in various countries. The touristic potential of a territory is constituted by the ensemble of the natural, economic and cultural-historical elements, which present certain possibilities of touristic capitalization and give tourism a certain functionality. Romania possesses (objective) elements that have a meaning for tourism, as well as a variety of means which can facilitate the specific activities for this field. Their dispersal in the territory is different, being on the one hand, objective agglomerations which have conditioned intensifications of means and resources which would emphasise them, and on the other hand, broad spaces in which all of these are dissipated.

The touristic potential of Romania is composed of a variety of forms of relief, springs with mineral and thermal water, lakes used for recreation, swimming and sport fishing, a valuable hunting fund amassed in coniferous and broadleaf forests, diverse landscapes from the mountain peaks of over 2000 metres to the plains, to the seaside and

the Danube Delta. The grouping of elements with touristic potential, the infrastructure and the development on the Romanian territory is the result of the connections established between man and nature along time, as a consequence of the historic and natural evolution, which has led to the separation of touristic provinces (regions, areas, centres, localities, etc.) each one reflecting a certain degree of complexity, as a touristic potential, infrastructure, as well as a way of performing the tourism activities. Consequently, the contour of touristic axes that go across various provinces, areas, centres, localities and objectives has been produced.

In this sense, there has been an individualization of the following regions: Maramures, Bucovina, Brasov, Banat, Apuseni, Buzău-Vrancea in The Carpathians and Subcarpathians de Curbură, Argeş-Prahova, North Oltenia etc. within which there are areas, centres, and secondary touristic axes comprised in a certain touristic system.

Romania possesses a great variety of natural resources which form a large part of the "basic" touristic product. These include the Black Sea beaches, the Danube and the rivers, the Carpathians and other mountain chains and the Danube Delta Biosphere Reservation. There are 16 national parks and 13 natural reservations which cover 7% of the country's surface. In Romania there is a vast biodiversity with many species of flora and fauna which are unique in Europe. Romania possesses the richest variety of large mammal species in Europe and it is a major passageway for the migration of birds. Their total surface is of 1,652,403 hectares. The tourist attractions can vary from hunting and trekking in the mountains to recreational walks and winter sports.

The Romanian structures of tourism aim at the following:

- Seaside tourism;
- The Danube Delta;
- Mountain resorts;
- Spa resorts;
- The capital and the county capital cities.

The structures of tourism from the seaside benefit from the shortest season, open, in average per year, for less than three months. The touristic season in the Danube Delta also functions for less than six months a year. As

a tourist destination, Romania's strong points aim at the following structures: geography and environment, culture and cultural heritage, infrastructure, transport and communication.

The geography and the environment are the strong points in the natural tourism potential through: the Danube Delta biodiversity (the Biosphere reservation which belongs to the UNESCO world heritage); the diversity of the national parks and of the protected natural areas (7% of the surface of the country) with forests, lakes and unpolluted rivers; the seaside and beaches of the Black Sea; the Carpathian Mountains; the Danube River; a large number of caves; the flora and fauna diversity (large number of unique species or with the highest density in Europe, especially large carnivores); 35% of the mineral water springs in Europe and of mofettes which offer a wide array of spa treatments; temperate-continental climate; good natural conditions for tourism activities (ski, mountain trekking, equitation, cycling, water sports, etc.).

The assets in culture and cultural heritage are represented by: the diversity of the heritage objectives-convents, archaeological sites, fortified constructions, including seven objectives/areas which are included in the UNESCO world heritage; medieval citadels; rural settlements where the traditional lifestyle can be experimented; museums with various themes; impressive artistic programmes-classical as well as modern; a wide variety of festivals, traditions, folklore; legends-Dracula, etc.

From the perspective of the tourism potential in the mountains, the most imposing areas are the following: Bucegi-Postăvaru, Piatra Mare, Parâng, Cindrelul, Șureanu, Retezat – Țarcu –Muntele Mic, Semenic-Aninei,Bihor-Vlădeasa-Muntele Mare, Rodna,etc., the touristic resorts and complexes that offer great possibilities of valorisation for the winter sports, mountain trekking, cave tourism, mountain-climbing, hunting, and sport fishing, spa treatment, religious, cultural tourism, ecotourism, etc.

The spa-tourism potential is famous on the international market because of the natural treatment factors, such as: mineral waters, mud and therapeutic gases, saline bioclimate, ionised-air bioclimate, phytotherapy (herbalism), partially exploited in the

national spa resorts (approx. 24) and the regional and local (or localities) spa resorts which are not certificated (approx. 36). In addition to these favouring elements, we mention the professionalism of the medics, as well as the variety of traditional Romanian spa treatments and medicines.

The touristic potential of the Black sea littoral constituted of the famous tourist resorts includes a wide array of elements, such as: the mineral waters from Mangalia, Venus, Neptun, Eforie; the sapropelic mud from Techirghiol and the peat mud from Mangalia; the chlorine-sodium filled water of Techirghiol lake; the marine bioclimate and other natural and cultural-historical tourist attractions, dissipated on approx. 70 kilometres between Capul Midia and Vama Veche.

The Danube Delta tourism potential is represented by its ecologic value, by the landscapes, fauna (ornithological and piscicultural),cruises and expeditions organised in special surroundings with cultural and economical traditions specific to the local Russian, Ukrainian and Romanian communities.

The tourism potential of the Danube River and the adjacent region impresses because of the attraction area preferred for tourism: the Danube gorge and the Iron Gates, Danube's lakes, etc.

Romania's fauna and flora potential, rich in scientifically interesting species, but also for hunting, with ecosystems unique in Europe, represents important premises for the development of the Romanian tourism.

The Romanian tourism industry is distinguishable for its speleological, hiking and climbing potential as well as for the extreme sports possibilities offered mostly by the mountainous area.

The modernization, revival and development of the Romanian tourism are influenced by the climate of Romania which favours tourism during the entire year because of the comforting thermal regime, the snowfall which allows the development of winter sports, the therapeutic value of the bioclimate being a mountain incentive.

Romania's touristic offer and programme are also favoured by the cultural-historical heritage, very representative for our county, because of the multi-millenary history of the

Romanian people, crystallized due to the following:

- The existence of more than 680 values of cultural heritage of national interest, such as 197 churches and monastery ensembles, 36 monuments and architecture ensembles, 11 castles, mansions and palaces, 70 urban architectural ensembles (civil buildings), 20 historic centres and archaeological sites, etc. A large part of the historic and art monuments are values of the UNESCO World Cultural Heritage (fortified churches, churches with exterior frescos, Dacian citadels, Sighisoara citadel, etc.)

- The Romanian ethnographic and folkloric treasure of a great originality is represented by the popular architecture, specific to the Romanian villages (from Maramures, Bucovina, Oltenia, Dobrogea, Transilvania, etc.).

- The craft industry, woodwork, the art of decorating, fairs and the traditional cultural-religious manifestations also represent the offer of a touristic product with a decisive role in choosing destinations.

- The revival and development directions of tourism aim also at the technical-economical potential of Romania, objectified through engineering works of art, bridges, dams, old stacks, salt mines and mines, old factories and railway station buildings, vineyards and studs, etc.

- Its geo-touristic position offers Romania several advantages due to the following:

- The presence of three natural components characteristic for the landscape and the social-economical structure of the country, components of great value and entirely European: the Carpathian Mountains, the Danube River and the Black Sea;

- The touristic transit function, because Romania ensures the connexion between the countries of Central, Nordic and Eastern Europe with the ones from the southern part of the continent and from the Near and Middle East;

- The European roads network with the seven road arteries and European corridors North-South (IX) and East-West (IV), between the railroad route and the Danube River (corridor VII), that establish the connections between the countries of the continent and the Black Sea basin.

In comparison with other tourist destinations, Romania has a weaker performance especially caused by the infrastructure regarding the road transport, but also as a consequence of some precarious aspects concerning the human resources and the public perception about the importance and value of tourism.

However, during 2005-2009, the number of arrivals of foreign tourists - including visitors a day - in Romania, by type of tourist destinations, has seen significant declines. (Table 1)

Table no.1 Arrivals of foreign tourists, by type of tourist destinations (Number of tourists)

Location	2005	2006	2007	2008	2009
Spa resorts	36372	36337	36252	27236	22724
Littoral	88182	61812	58191	41569	31607

Analyzing Table 1 we see that foreigners prefer destination, Bucharest and other cities in the county, at a rate of 74%, followed by other towns and tourist itineraries (11.2%) Mountain Resorts (7.3%), Seaside (4 %), Spas (2.3%), the Danube delta (1.2%).

The "Bucharest and other county capital cities" and "Other localities and tourism itineraries" categories include not only the business or official visitors, but also the ones who get an accommodation on their way to other destinations and the foreign visitors who make short shopping trips, the ones who participate to events or who visit tourist attractions

By analysing the main destinations preferred by Romanians, except for Bucharest and other cities, it resulted that these were the mountain resorts (16%),

littoral (14%) and Spa resorts (13%), as shown in Table 2.

Table no. 2. Romanian tourist arrivals by type of tourist destinations (Number of tourists)

Source: INSSE, www.statistici.insse.ro

The qualitative research performed on the Romanian hotel staff and on the travel organisers indicates the following main market segments for the holidays in Romania:

- *Pretentious—elitist*: hunting, holidays with friends on Prahova Valley, Breaza – “Davos of Romania” and the golfing capital; Danube Delta biosphere reservation; wine tasting (Transilvania, Moldova, Crişana, Maramureş);

- *Cultural tourism combined with ecotourism*—young professionals: Transilvania; Maramureş; Bucovina; Litoralul Mării Negre; Delta Dunării;

- *Middle-class families*: Prahova Valley; Black Sea littoral; visits in the surrounding areas in order to spend time in nature, for example with the occasion of celebrating the 1st of May;

- *Visits to see the parents* for Christmas and Easter;

- *The social category called “working class”*: Black Sea littoral; countryside vacation—either at relatives, or in guesthouses; visits in the surrounding areas in order to spend time in nature; visits to see the parents for Christmas and Easter;

- *Older couples*: visits to see their children, to the city; social programmes (i.e.: “a week of recovery—a week at the Black

Sea littoral”); visiting the monasteries (i.e.: Bucovina monastery); museums, castles;

- *Young people—in groups*: the Black Sea littoral, especially Costinesti resort and Vama Veche resort; active tourism in the Carpathian Mountains; Danube Delta; camps (Eforie Nord, Năvodari, Cetăţile din Transilvania, Rânca –în Munţii Parâng, Bucovina).

- There are major variations of the types of amusement trips, between rich people and poor people. The spa resorts clients is almost entirely internal, especially elders with low income, who go to these resorts with the help of treatment tickets offered by the social system.

- The low-income clients have the tendency not to choose a hotel accommodation, because they cannot afford the costs. They rent apartments, guesthouses or camps.

3. Conclusions

Considering that the following decades will bring about significant changes in the world demographic structure (average age, percentage of the ethnic and religious groups), the trends of the international tourism demand of tourism products/ travel arrangements will develop in all the meridians of the world. The population of the world will double in the next 50 years, the life expectancy and, implicitly, the average age of the population will grow, and the seniors (retired) will have more time and resources to travel. Therefore, the tourism products demand will be elastic and the increase in the interest for touristic programs/ holidays with possibilities of knowing the culture and history of the nations of the world will present a greater interest. Even if the interest is in novel experiences, the majority of potential tourists will want to be able to continue the healthy lifestyle when travelling and the quality of the tourism offer will influence the choice of a touristic destination.

Subsequent to this analysis, in the future it is compulsory to aim at achieving a more uniform distribution of the available accommodation capacity, at the level of the country and the regions, with the purpose of ensuring a better tourism activity.

The need of effort-coordination at a regional, as well as national level in order to accomplish grand projects in the domain of the infrastructure, especially of the transport and communication, which has to be correlated with the development process of the territory, which presupposes the coordination of all the projects with the spatial implications and solving the possible conflicts occurred in this context of profound transformations of the society. In this sense, an assessment, classification and identification model of the most appropriate and efficient ways of valuing the tourism heritage has to be established, using for this purpose a multi-criterion analysis of delimitating the touristic regions, together with a crystallization of the priority actions for each particular case. In conjunction with the touristic areas delimitation, the development of the territory and the appropriate policies in tourism, we have to find solutions regarding the protection of the environment from the tourism activities with a direct impact on the environment.

The starting point in establishing the strategy for improving the position of the destination competition is constituted by the determining elements of competition, which are mainly given by the resources (natural, cultural, of capital, of infrastructure, human), by the quality and structure of bidders, by the behaviour conditions of the demand and by the adaptation of the offer. However, all these have to be correlated with the provisions of the Declaration of Rio and with the enactment of Agenda 21, according to which the sustainable development of tourism represents the global strategic option for this century. The management and the sustainable development of tourism are applicable to all the forms of tourism, in any type of destination, including mass tourism, as well as other varied segments of tourism.

Patterns of Human Resources in Inter-organizational Collaboration

Serghe Dan

„Alexandru Ioan Cuza” University of Iași

dan@bxb.ro

Abstract

Redesigning business processes from the perspective of collaborative inter-organizational networks, various modeling techniques and store information from communities of practice in data warehouses, are aimed not only to manage the knowledge of a business process, but also, to manage the knowledge created and applied (innovation) in the process. My approach to modeling derives primarily from an intention to integrate the organizational management process in order to produce an innovative result, a higher one compared with a mechanistic management system based on the amount of organizational knowledge.

Key words: inter-organizational, Business Intelligence, network, creation.

J.E.L. classification: O31.

1. Background

Research directions in the development stages of innovation and innovative processes have evolved over time, from an innovative perspective encroached within an activity carried out by an entrepreneur (as a entity that creates possible and many innovative combinations), to a vision of design innovation in processes and innovative structures larger expandable (ie, within the internal organizational environment, as a generated and stimulated response by market demand). In recent decades, innovation is explored from a design perspective on networks and systems of organizations. Inter-organizational networks have grown considerably in importance.

The first two approaches are regarded innovation as a result of a linear process, performed by the entrepreneur, or the company, applying science in a logical and

structured approach and applying causal factors in workplace.

Linear innovations ignore feedback loops (innovation process is not induced and is not necessarily result in linear chains of activity but, rather, is a recursive process). On the other hand, innovation may have unforeseen implications initially, and be adopted in industries in ways difficult to predict [16].

Von Hippel, argued that the source of innovation consists in the relationships between manufacturing companies and their suppliers or, in particular, in the relations with their customers [29].

In recent decades, field of analysis for innovative processes is designated by the network metaphor (interdependencies between organizations represented by informal ties connecting the various entities and relationships and which intersecting formal relations existing in organizations). Networks becoming more complex by the combination of various features and nodes who include resources, knowledge and various arrangements (interconnected networks). The scholars discussed the cultural context according to account the different forms of perception (in a network actors have different perceptions).

Networks contribute significantly to potentiation innovation capacities of firms by exposing them to new sources of ideas, allowing quick access to resources, and the possibility of knowledge transfer. Networks can also makes possible for companies to achieve objectives that could not pursue them individually [26].

Miles et. al. make in relation to research and structure a scenario in which innovation and economic development are dependent on "the power of collaboration". In this research agreement, collaboration is defined as a process in which two or more parties working together to achieve common benefits of collaboration [21][20][19].

The quality of collaboration depends on many inter-organizational relationships and interactions between groups of employees who interact, negotiate, and provide value to partner organizations [28].

Management policies are developed by integrating the determinants of inter-organizational dynamics: structures and mechanisms, social relations, intensity relationships in the network, level of trust and risk [11].

On the other hand, the characteristics of organizations are very important: absorption capacity, intra-organizational transfer capability, motivations.

2. Looking for systematic patterns

The ability of organizations to collaborate with other organizations is dependent on its ability to turn internal collaboration [20].

Internal collaboration is not facilitated when the functional departments in the organization are highly specialized and isolated from the rest of the organization.

Miles emphasizes that organizations which have developed a strong capacity of their employees ability to work together, are more easily able to develop external communities to collaborate in the future.

From the description of collaborative structures that are composed of firms belonging to different industries and where colabolare skills allow them to pursue a common strategy for continuous innovation, two features can be drawn: collaborative relationships are voluntary nature and also facilitates collaborative relationships generation of knowledge, and sometimes through a proper strategy, knowledge is transformed into continuous innovation.

Collaboration by creating and applying knowledge to generate a process of continuous innovation, is based on complex behavioral rules derived from several factors [21][14].

In the many factors affecting the collaborative, there are three main categories investigated more obvious: strategy, structure and management philosophy [19][14][22].

Reported in hierarchies characteristic of organizations and markets (characterized by their mechanisms and control systems), inter-organizational networks gets a touch of distinctiveness by the following

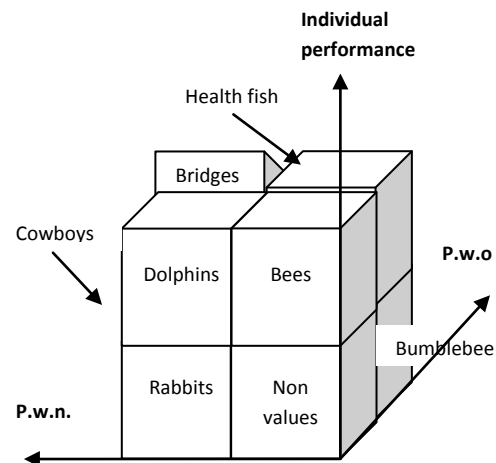

characteristics: mutual trust, cooperation, characteristics of relationships that are created, additional interdependence and an informal climate oriented toward mutual benefits [1][10][12][18][31].

Based on individual characteristics, as a center of basic constituent of collaborative network. I designed a typology of collaborative behavior of individuals by combining three dimensions:

- i. Individual Performance - delivering results through the accomplishment of their tasks;
- ii. Performance within the organization - getting results from collaboration within the company;
- iii. Performance in inter-organisational collaboration - getting results from networks and systems of organizations.

By combining these three dimensions, I set up eight blocks, eight general types of human resources who will engage in network-type systems and will form elementary nodes of the collaborative network:

Fig. 1 Typology of collaborative behavior

1. Non values - meaning employees who fails to produce results, performance, and to bring added value, even when working individually, but even when working in collaboration with colleagues in their organization or with potential colleagues from another organization.

2. Bees - designates employees who easily able to obtain individual performance and achieve their individual goals, within their organization not working efficiently or at all

and no performance gain by working with other employees, but, they get results and collaborate efficiently with new people, unknown, possible future mates in the creative community. This is the typology of the active employees and always eager to external activities, trips, which always feel the need to find places in many places outside the organization (for example, courses, workshops, exhibitions, product presentations, work communities or creative communities).

3. Rabbits - means employees who work together effectively with other people who are in continuous motion both within the company or outside, but it fails to produce results, performance, to bring value when working individually. During their activity, they are found everywhere, interacting with others, but their tasks are affected.

4. Health Fish - are employees who get good results both individually and in collaboration with their colleagues, but do not receive performance or collaborating with individuals from outside the organization. There are those who generally identify with a second family company, with an intimate setting where they spend their daily lives and are reluctant or feel uncomfortable, helpless, they are blocked when they should interact with the outside world.

5. Bumblebees - are employees who do not deal effectively with their own tasks, fail to focus on individual goals also are not sociable and do not fit into the new collectives, but getting good results from collaboration with their mates, they communicate and collaborate better with colleagues within their own organizations, which can maintain a friendly and a family environment. They are always active and they can be found in different departments or collaborating with colleagues in the office.

6. Cowboys – meaning misfits employees, dissatisfied with their own company, which not channel their efforts to achieve the objectives because of their frustrations, but still have some skills. Although it is a rare case (because normally they will not last too long in his company), however in inter-organisational community they can find an outlet and put their skills to gain performance by working with new or different people from outside of the company.

7. Bridges – meaning the employees who receive performance on all levels, whether working individually, they are capable in their employment and reach their goals, whether they interact and collaborate with all kinds of people.

8. Dolphins - is the typology of employees who get results and performance only working individually, but they have an attitude that is contrary to the collaboration. They are effective on certain areas or activities of the company (eg sales). For this reason, many companies focused on collaboration, prefer to keep these employees, but does not promote them.

3. Framework for evaluation

Communication between employees who are involved in a network of inter-organizational collaboration can be made directly or can be made by the mediators for the transmission of messages. Face to face communication provide richness.

To assess intensity of the communication and the spatial proximity and inter-organizational structures for collaboration, I made a study of 56 companies. In this study, I evaluated the modes of communication used and the intensity of communication with partners (suppliers, customers, NGOs) in collaboration network.

The respondents in this evaluation had a choice between seven different categories of mediators of their communication: e-mail, messenger, telephone, video conference, fax, face to face, group meeting, and between five different categories to rank the intensity of the communication: daily, weekly, frequency to two weeks, monthly, less than monthly and never. I have held daily and weekly communication as a communication frequency and intensity, the other categories I considered as low or zero frequency.

In setting up communication channels is important to consider the role of spatial proximity. The spatial proximity seems to facilitate face to face communication and knowledge exchange.

This study investigates how commercial and non-governmental organizations organize and structure their communications to develop and implement sustainable

building innovations from inter-organizational collaboration.

The innovation processes aimed at sustainability, are modelled as inter-organizational innovation processes. To search for answers to the research question an empirical research project studied 56 sustainable projects in Romanian companies.

1. Positive results (which have brought more, something new on every level of the value chain) of the collaboration, were obtained in those networks in which the share was based on informal structures of communication at least 70% (which favored the transmission of tacit knowledge, knowledge crucial in developing innovative value chain segments). Formal communication structures are used mainly in reporting stages and progress of collaboration, and in activities related to budget and financing activities.

As a hypothesis for future research, this mix of formal and informal communication can provide a measurable indicator of quality of communication in inter-organizational collaboration.

2. To expose mediators and communication intensity, I present the results of the study conducted on the 56 companies in the following chart:

Fig. 2 Communication characteristics

All the 56 companies used e-mail, messenger and phone as a mode of frequently communication, but messenger is not used as a mode of non-frequently communication. Considering that the people had to travel in order to communicate face to face, eight organizations used this mode of

communication (and also groups meeting) as an important facilitator of knowledge transfer and creation. From this observation, I took the third research direction:

3. ITC systems grow in importance in terms of their role in decision-making group, structured Business Intelligence Systems on collecting and processing information becomes more relevant in facilitating communication and coordination activities of individual members.

Using the external knowledge and transfer methods. Processes of negotiation in inter-organisational collaboration become more complicated in accordance with the increased participation in decision making.

Evaluation and analysis of seven inter-organizational collaboration [28] found that participants had limited systematic mechanisms able to transfer knowledge back into the organization, knowledge created through collaboration. In this study, the author has examined best practices in collaboration, but concluded that the excessive use of communication and in particular the type of informal, face to face communication, the large number of connections developed at the individual components as nodes of the network, have contributed to the inconsistent use of technology, systems and processes.

Several interviewees confirmed that the starting point for using knowledge of the results of inter-organizational collaboration is the personal effort of the employees involved, effort to plan and design implications for their organizations, knowledge gained, and more, to then identify the appropriate internal mechanisms for knowledge transfer within the organization.

Operating in an unpredictable environment and to some extent under the influence of some uncontrollable circumstances, organizations involved in inter-organizational collaboration networks are faced with the need to control a continuous process of adaptation and transformation, a process characterized by the speed of change and high frequency interference, which does not allow control of the organizational managers. [9].

In accordance with an emerging vision, identifying and managing change must be a responsibility of all stakeholders in a collaborative project, therefore it is expected

that participants be competent, adaptable, willing to assume responsibility for identifying deficiencies and implementation of collaborative solutions [23].

5. Discussions

The objectives of my research approach, have as their purpose, proposing a coherent set of actions for the management of organizations to improve their ability to obtain additional value through participation in collaborative inter-organizational structures of continuous innovation.

By identifying factors and translate them into models follow:

- to explain the emergence, development, configuration, maintenance and dissolution of collaborative networks,
- to explain the formation of inter-organisational collaboration structures that is self-organizing, and,
- to identify predictors for inter-organisational collaboration models.

In relation to the current level of research on the inter-organizational collaboration has been shown that the partners in a collaborative network have limited systematic mechanisms able to transfer knowledge back into the organization, knowledge created through collaboration.

The interconnection between internal company networks and the networks created in collaborative community is poor, excessive informal communication such as "face to face" showing inconsistent use of technology, systems and processes [28].

One of the challenges ahead is to argue and demonstrate the potential ability of a Business Intelligence System to provide the necessary levers and tools for efficient management of collaborative networks.

Companies must have the tools to enable them to receive immediate results and knowledge from the inter-organisational collaboration, their correct analysis and making appropriate decisions in the shortest time possible. Moreover, for the marketing of innovations generated at the network level, information from external environment is vital, companies must be aware at all times that are most wanted products on the market, that are most profitable customers, what new products and services should they offer to remain efficient.

In addition to competitiveness, companies must constantly be concerned with optimizing their value chains and improve business decisions, to have achieved success in trading the collaborative innovation on the market.

Evaluation of Business Intelligence System involvement in innovative collaboration could be made by:

- the ability to extract the essence of information developed in collaborative network;
- development of intuitive information, qualitative assessment of how the information collected and synthesized are offered on the network partners (eg, information that is offered to customers before and after the sale, giving customers the information needed to make smart decisions to purchase);
- the effect of the collected information processing from the collaborative network and the absorption capacity of the system developed within the organization;
- the effect of using information gathered and summarized by evaluating how they serve the network partners.

Building and Maintaining Relationships with Customers through the Website

Severin-Humelnicu Anamaria
„Transilvania” University of Brasov
anamaria.humelnicu@unitbv.ro

Abstract

The website is very important in e-commerce, because it is the place where business is conducted and where company and customers meet. This paper presents the characteristics a website needs to have, in order to succeed in the online marketplace. The objective of many online companies is to maintain a long and profitable relationship with them. The website gains in this case the greatest importance.

Key words: website, e-commerce, customer, relationship.

J.E.L. classification: L21, L 81, M 31.

1. Introduction

Online customer retention is as important as customer acquisition. It is not easy to determine visitors to return on the site and to make online purchases. However, this is the only way to succeed when doing business online. It is noteworthy to mention that in creating a site, online marketers should be aware of which are the potential customers that need to be attracted to the site. To create content for your website involves a hard work, especially when running a business online through the site. It is necessary to add current and attractive information on the site, as well as having ongoing promotions and permanently new products. This is one of the conditions to keep customers happy and make them return. If a site succeeds to impress a visitor, then that visitor will have a reason not to leave the site, and may be encouraged to buy on that site, and if he is satisfied, he will recommend the site to other people he knows.

2. Website content

A good content sells a product, for which the site content must be given much importance. To become successful in online business, the website needs to be simple, easy to build and to maintain. Its major purpose is to attract traffic and to convert visitors into customers. There are several factors that are required to be taken into account when creating and designing a site for an online shop. Unfortunately some of them are ignored by those who conduct business through the Internet. To become successful in online business, the website needs to be simple, easy to build and to maintain. Its major purpose is to attract traffic and to convert visitors into customers. There are several factors that are required to be taken into account when creating and designing a site for an online shop. Unfortunately some of them are ignored by those who conduct business through the Internet. People in general are always in a hurry and that is the way they are also acting on the Internet. A company has to capture their attention on the site in a very short time, usually between 10 and 30 seconds. For this reason it is said that the website must be built for speed. The key to a fast loading web site is to use graphics that are within certain dimensions, compressed pictures and to use flash technology only if it is really needed. It is required to identify the target segments and to ensure that the site meets their needs. It is essential to know the visitors and to build the site according to their preferences. We must not ignore the fact that the site has one main purpose, namely to sell the product or service. Well-constructed sites offer credibility and gain trust among visitors. Credibility is very important, because even the most professional website designed to attract potential buyers will fail, if they do not trust that online store. The first step to

build trust and credibility is to display on the site a privacy statement and various contact possibilities. Site navigation must be simple, easy and intuitive. It was already demonstrated that one of the main reasons for online shopping are convenience and easy navigation through the site. Given that visitors do not have the patience to navigate the entire site to find what you're looking for, it is also very important to include a search function on the site.

The site should be consistent in layout and design. The colors and theme must remain the same for the entire website. It is disturbing for visitors to navigate the site and to have the feeling that as they navigate through several web pages of the same website, they are actually visiting another site. Feedback forms posted on the site and forms that allow potential customers to ask questions about products add interactivity to the site. Customization is another key element which can build confidence and increase sales. Customization facilitates the activities of cross-selling and up-selling when the customer buys online.

It was found that the following four main factors encourage visitors to return to a site: high quality content, ease of use, fast loading site, frequently updated site. [1] Among these factors, the content is probably the most important. It is important to have the right content, but also to display the right information at the right place at the right time. A great content site helps people make the right decision and also attracts visitors through search engine optimization. The site requires a user friendly and easy navigation. Neither the form nor the structure of the site should be complicated or too wide. No visitor will "get lost" in a well-structured site.

For improving website performance, the following needs to be taken into consideration: content development, adding or improving onsite search, site upgrading and redesigning, enhanced onsite merchandising features, cross-selling and up-selling, personalization or customization, adding customer-generated content and reviews and last but not least web analytics.

Online buyers are constantly searching for sites with updated content. Especially the active Internet users navigate from one site to another, from one page to another. Perhaps they are exactly the visitors that a company

wants to attract: those who want to stay online for several hours, searching for products, services and information of interest. [2]

Site content may be suitable for viral marketing when it proves to be interesting and useful. Internet users in general tell friends about it, or they send them a link. A good site makes people talk about it. But this is not easy and requires increasing the value of content. The more useful is the information and the more compelling the content, the more users will visit the website.

A study by Rosen and Purinton (2004) addressed the importance of quality of a website to a user's intention to revisit the site. Thus, sites containing coherent, understandable, an adequate design and less complex are revisited, because users are satisfied. The text posted on the site should be short and concise, avoiding long sentences. In terms of graphics, the site should be arranged clearly and not to be overloaded. [3]

The ability to keep visitors' interest to a site is determined by the attractiveness of the site, known as website stickiness. [4] To enhance the stickiness of the site, content will be updated frequently and the information will be accurate and interesting. Attractiveness is also achieved by providing very good customer service, which in turn will transform prospects into customers and make them buy.

When creating a website the specialist should be aware of the potential customers which need to be attracted to the site. The creation of a commercial site starts with the question, to which segment it is addressed. Prospects should be defined in terms of their demographics, their type, but also in terms of their motivation, the way they think and feel. Potential customers tend to resemble to existing customers. When configuring the site, specialists will take into account the consumer behavior, the knowledge gained from monitoring their behavior. In order to succeed in an online environment, a company will focus on the following five objectives:[5]

- attract visitors to the site
- retain visitors on site as long as possible, with the purpose of determining the visitor to buy a product online

- convince the visitor that the retailer is the best one
- convince visitors to revisit the site in order to obtain more information
- obtain permission to communicate with visitors

Companies must realize that the site is a strategic communication and marketing tool, because through individualization and interactivity it enables business growth and achieving high performance. A site used as a marketing tool is that site, that: [6]

- sells and brings the consumer closer to the purchase decision
- offers customer support;
- promotes technology;
- is interactive, counting opinions and satisfaction or dissatisfaction of the customers

Internet users surf the Internet to find a product, service or information. The more they get of what they want, the more will they be attracted to the site.

What retains consumers to a site is not the advanced technology. It is the content which it offers exactly what they want: useful information and great benefits. The most important thing a retailer gets from its visitors is the permission to talk to them. Whenever a company obtains an e-mail address from visitors, it should give them something in return.

Users understand the value of their contact details and they will not disclose their data easily, just for a good reason. What companies can offer in return could be a free catalog, a forum, a report on a topic of interest, a contest, a membership or subscription to a newsletter, and the list may continue. Of course, the incentives offered to visitors are extremely important. Here we mention prizes, discounts or additional services.[5]

Online retailers get only four seconds to make the first impression through the website. In such a short time, no visitor succeeds in reading the content of the site, but it is enough time to create an emotional relationship based on the reaction to color, layout, design and navigation. If during this time visitors have not been attracted, they will most likely leave the site. [7]

The goal to be achieved by the website is to deliver a clear message to Internet users.

The challenge in building a website is to take into account the needs of the clients. Although some sites are visually attractive, they have gaps in content. Other sites send a message, but it is lost among too many images on the site.

3. Relationships with customers

The website is the primary medium by which customers interact with the company, in order to meet their needs. From the commercial point of view, the website allows electronic access to products and services, anytime and anywhere. In terms of exchange of information, the website provides relevant information for clients and receives information for the benefit of the company. The information gathered may be used to improve activities and services for clients or create new products. In terms of effects, the site helps customers meet their needs by making good decisions. [8]

If users are active shoppers, they probably may not remember every online shop that they made a purchase at. But, if the consumer it is interested, he may subscribe to their newsletter. In generally, newsletters have the great advantage of keeping the company's name and products fresh in the mind of users. It is recommended not to send newsletter too often to the subscribers, because their e-mail will be overloaded in case other companies do the same. In this case they won't be interested any more. The company must send an e-mail once a month or twice, which offers valuable and updated information. In the newsletter, subscribers should be informed of special sale prices that the company might be promoting, or of a new product list.

A customer-oriented website takes into account the customers and their needs. The website will not only meet the basic needs of the customer, but also will delight customers by fully understanding and meeting the different needs that different customers have. A customer-oriented website attempts to identify customer needs, offers benefits adjusted to their specific needs and help customer to fulfill their needs.

Online shops should offer high quality products, usually at lower prices than any offline offer. The customer is in control and he is able to change the supplier and to move

to the competition, just by one click. This change is often not due to the reason of the price charged by the online retailer, but due to the lack of customer service. Many online retailers believed that their customers will use the abundance of information to find the best prices and they did not take into account other aspects of the online buying experience. Once the competition has intensified, online companies have realized they cannot succeed by relying solely on price. For this reason they have developed strategies to provide value to customers, in order to differentiate themselves from competitors. Only the online presence is not sufficient for having success. Success comes with offering good products at fair prices and especially by providing excellent online customer service.

The website is very important in e-commerce, because it is the place where business is conducted and where company and customers meet. For this reason, the site will have those characteristics and capabilities that enable firms to acquire and retain customers. E-commerce sites are easier to leave than physical stores.

Websites can be used to build communications and exchanges by providing detailed and accessible information on products or services, on the company, on the uses or processes surrounding the products or services and on user comments and advice. The website can also provide interactive question and answer or problem-solving services and an opportunity for current and past users to exchange information, views and advice. [9]

We mention the important features that make an effective website, as identified by Sexton D. [10]. The web site should therefore:

- Be easy to find
- Download quickly
- Be inviting, attention getting
- Provide comprehensive content, to cover all the areas of interest to the target customer.
- Have the right tone
- Be "sticky", fresh content and information tailored to the visitor's needs and interests.
- Be viral, to get visitors to recommend it to others.
- Be easy to navigate
- Be personal, so the visitor should feel like a member of a community.

- Support company's product or service market strategies.

The website has a personality that is required to be continuously developed and improved. It is important to create a unique, consistent site and to be easy to remember. As visitors interact with the site, they will develop a clear picture of that company.

E-commerce efficiency depends to a large extent on how well the company is able to deliver value to its customers and how it cultivates relationships with them. An online company looks to acquire best customers and to keep them coming back again and again and to maintain a long and profitable relationship with them. The website gets a high importance because it is a way to identify a company and its quality is consistent with the company's performance and professionalism.

Customer-Company Relationship on the Internet

Severin-Humelnicu Anamaria
„Transilvania” University of Brasov
anamaria.humelnicu@unitbv.ro

Abstract

Consumers now occupy a key position in e-commerce activities carried out on the Internet. They are now provided with more control. Their behavior becomes a challenge for online companies. Understanding consumers in cyberspace is vital for communication with them and for online marketing activities. A well-organized company knows its own customers, which are the greatest asset a company owns.

Key words: Internet, client- oriented, relationship

J.E.L. classification: L21, L 81, M 31.

1. Features of online relationships

The progress in Internet technology allows firms to customize products and services for each client and to deliver personalized services, which is not possible in the offline marketplace. As online companies know more about individual consumers and track their buying habits, customer relationship management becomes easier to accomplish. Once the relationships become stronger and lasting, both business performance and the degree of customer loyalty will increase. The online space is able to provide the means necessary for an interactive dialogue with customers and raise the expectations of each of them.

Chaffey D. and Smith P. highlight the lack of customer relationship management in the fast moving online world: [1]

- customer expectations are often higher than those of the online world;
- customers` raised expectations are regularly crushed by previously successful offline companies;
- customer e-mails are left unanswered for days;

- immediate responses are expected, but more often than not, are not delivered;
- satisfying customers is simply not enough to keep them;
- surfers visit fewer sites, but spend more with them.

However, specific features of the Internet, such as loss of spatial and temporal distances between retailers and buyers, and interactive transmission of information make the Internet an ideal environment for building, maintaining and strengthening customer relationships.[2]

One of the main goals of Internet marketing should be to develop a large database with detailed information about current customers, but also about the potential ones. The database is responsible for the development of competitive products and services that will meet the needs of each client. [3]

Most companies are faced with an increasingly sophisticated customer base, requiring a higher level of services for customers, even through multiple channels. To reach customer satisfaction, companies need to maintain consistency across all channels of interaction (such as the Internet, e-mail, phone and others) and in all the departments in which a company interacts with customers (sales, service and marketing). To meet this challenge, many organizations are considering adoption of e-CRM (electronic customer relationship management). [4]

The Internet offers multiple ways for a company to learn about its customers and their needs. By using certain tools can be summarized the products that were purchased on site and what search strategy was pursued before the purchasing. Customers are able to write reviews on existing products. There is also possibility fill the online feedback form on the site about the company and its products.

Regarded as a marketing channel, the Internet has both unique features and characteristics with other marketing channels. The Internet offers the possibility to store vast amounts of information to search and disseminate information, to provide information on request, to serve as a trading environment and as a physical distribution medium for certain goods, for example software.

The following advantages of the Internet are noteworthy to mention: [5]

- is a great mean to reach a certain segment of the population;
- offers very good possibilities for segmentation of the public, avoiding to spend money to send the message to people that have no interest in it;
- allows customizing messages based on the interests of those who will be exposed;
- amount of information available to consumers can be very high;
- is a captive media, those who access the Internet focus on the monitor;
- provides a high interactivity;
- offers unlimited creative opportunities (can be combined with image, sound and motion);
- allows various forms of Internet advertising from banners to newsletters, search engines, mailing lists, pop-ups;
- allows various methods of payment that can be tailored to each client's needs
- has great perspectives for development.

As the major disadvantages we can mention the low number of Internet users in some areas, small budgets for communication or poor development of online payment systems.

The Internet offers some important features for marketing, like interaction, personalization or measurability. [6] Perhaps the most important one for the marketing activity is interactivity, which allows bidirectional communication between companies and customers. Customization involves providing personalized service to each client depending on his preferences. Measurability refers to automatically obtaining of detailed statistics on the number of visitors to a website, their profile and preferences, advertising effectiveness. The Internet is a unique opportunity compared to other media in terms of communication and

advertising, because it allows easy exchange of information.

2. Focus on customers

In the Internet age, the client has access to a considerable amount of information, at global level. The challenge lies in the fact how he can use this information. Customers are now provided with more control. Their behavior becomes a challenge for online companies, because of the increasingly high expectations. Consumers now occupy a key position in e-commerce activities carried out on the Internet. Understanding consumers in cyberspace is vital, not only to communicate with them, but also for future online marketing activities like website construction, selection of products that will be offered online and for choosing marketing tools and strategies necessary to the online business. A company that does not learn about their clients cannot communicate effectively with them and cannot develop a solid customer-company relationship based on trust.

The emergence of electronic commerce has changed many aspects of traditional business and prompted the emergence of new companies with new business models and new business opportunities. Companies are challenged to rethink the existing relationship between the organization and its customers. Although repeatedly stated that the Internet has changed the basic rules of relationships with customers, it has not changed that customer orientation leads to sustainable development and to achieving sustainable profits.

In order to create and maintain loyalty, companies have to understand that the Internet is primarily a client-centered environment. The customer should be regarded less as a target, but more as a partner.[7] Despite the fact that the online space is risky and has high level of uncertainty, customer loyalty may be stronger in the online space. Customers are looking for those companies that feel they can trust. In this situation, trust becomes more important and more powerful than price.

A well-organized company knows its own customers. A good way of viewing customers is as a core element of the company. In fact,

customers are probably the greatest asset that a company owns. Like any other asset, it must be identified, maintained and maximized the revenues from it. This requires customer knowledge. [8]

Consumer behavior in the online marketplace is not totally different from the behavior in the physical environment. The virtual space presents some disadvantages, that online store managers must know how to counteract. In general, customers need to build trust in order to make purchases.

Customers are looking for those companies that they can trust. In this situation, trust becomes more important and more powerful than price.

Consumer confidence is vital in electronic commerce, characterized by the lack of contact with store personnel and the inability to touch products that customers would like to buy.

Customers want to know much about a product and its features, they want detailed product descriptions and images of them posted on the website, and customer support. An online shopping experience begins with the website. The site must attract or reject a customer. In the dot.com era, specialists believed that a Web site is especially attractive if it has a pleasant and sophisticated design. They omitted however to take into consideration that this didn't not allow fast loading of pages.

Different studies over the years have demonstrated a general truth of the market economy: as consumers have more power, the companies become more responsive and customer satisfaction is higher. When consumers have a multitude of options and access to information about these options, and low costs for transfer to the competition, then the customer is in control. Companies that fail to focus on customers, will lose. Consumer confidence is the key to a successful online store. Currently, customers have a relatively low confidence in online shopping. Late deliveries, additional delivery costs which are not posted on the website and incorrect information about the products, unsecure payments have a negative effect on consumers' trust. For this reason, online stores should adopt necessary measures to build confidence and develop e-commerce.

Online shopping differs from shopping in traditional stores. The main difference is the uncertainty that is manifested in the ordering and acquisition process.

The most powerful online retailer, Amazon.com has developed a passion to serve the consumer. Over time, Amazon.com has developed from a "dot.com" to a multinational corporation, a leader in the online retail industry. Amazon.com is characterized by two important goals: customer satisfaction and company growth. The founder of Amazon, Jeff Bezos said repeatedly that he wants to make Amazon.com the most customer-oriented company, knowing that a good reputation has a great impact on potential customers than any advertising campaign. Amazon.com deals obsessively to make each customer contact with the company a unique personal experience. The visitors of Amazon have a unique combination of advantages: a huge variety of products, enormous choice, user-friendly site, convenience and other.

Like the offline marketplace, in order to attract customers, the company needs to offer the right products to the right client. Goods or services must meet customers' needs.

To build better relationships with customers on the Internet it is required to identify and to maintain the most valuable customers.

Coordination between the Common Monetary Policy and the National Fiscal Policies – Principles, Methods and Difficulties

Socol Cristian
Socol Aura
Marinaş Marius

Academy of Economic Studies, Bucharest

socol.cristian@economie.ase.ro

socol.aura@economie.ase.ro

marinas.marius@economie.ase.ro

Abstract

The European model's entry into the third integration stage – The Economic and Monetary Union – has changed the conception of the macroeconomic policies. The „one for one” principle changed into the „one for all” principle. Within the Eurozone, all the member states can share both the benefits and also the costs of a common monetary policy, which should be combined with the national fiscal policies, elaborated by each country which is member to the Eurozone. Our research proposes an analysis of the technical difficulties in achieving the common monetary policy – national fiscal policies mix within the Eurozone.

Key words: monetary policy, fiscal policy, Economic and Monetary Union

J.E.L. classification: E61, F15

1. Introduction

The basis of the Economic and Monetary Union have been settled during the Maastricht Treaty, when the strategy for launching the unique currency was settled and the institutional arrangements related to the union's operation were clearly settled. The provisions in the Maastricht Treaty represent the finality of a sinuous way in settling a monetary union, clearly specifying the detailed operation of the system, including the statutes of the Central European Bank and the terms in which the monetary union was going to be started.

The bases of the EMU operation Treaty have an interesting history. In view of the high heterogeneity of the macroeconomic conditions existing in the EU member countries, Germany –, being confident that the price stability was the relevant indicator related to a country's macroeconomic performance, proposed to settle conditions for the Eurozone acceptance to other EU member countries. According to this country's position, the acceptance to the monetary union should have been selective (based on meeting the nominal convergence criteria) and it should provide a country's impossibility to “achieve” the status of a train jumper.

On the other hand, the introduction of a unique currency was involving the necessity of a single interest charge, a unique rate of exchange compared to the third party countries and, implicitly, a unique monetary policy. Moreover, the need for a single central bank. Even though it had a complicated structure, the new European Central Bank (ECB) coexists with the national central banks. The European System of Central Banks (ESCB) includes the new specially created European Central Bank (ECB) and the central banks of all the EU member countries. As not all the EU countries joined the monetary union, a new term has been established, Eurosystem, which refers to ECB and the national central member banks. The Eurosystem implements the Eurozone's monetary policy, it coordinates the exchange operations, in accordance with the finance ministers from the member countries, it owns and manages the official foreign currency reserves of the countries which are member to the Economic

and Monetary Union, it monitors the payment systems and it is involved in cautiously supervising the crediting institutions and the financial system (Baldwin and Wyplosz, 2006).

The Treaty mentions that the main task of the Eurosystem is to provide the price stability, but the terms used for this objective are vague, as they do not provide an exact definition of the price stability. However, the Eurosystem chose to explain the price stability as an annual increase below 2% recorded by the harmonized index of consumer prices (HICP).

2. Difficulties in coordinating the macroeconomic policies within the Eurozone

The price stability, a low interest charge, sustainable public finances, the extreme balance, they all represent benefits for the Eurozone member countries. Within the Eurozone, we may define two types of coordination related to the monetary and fiscal policies: the budget policies/monetary policy coordination between all the countries included in the Eurosystem (The European Central Bank + the central banks of the Eurozone member countries) and the coordination between the national budget policies of the Eurozone member countries.

The relation between the two macroeconomic policies may be analyzed from three points of view:

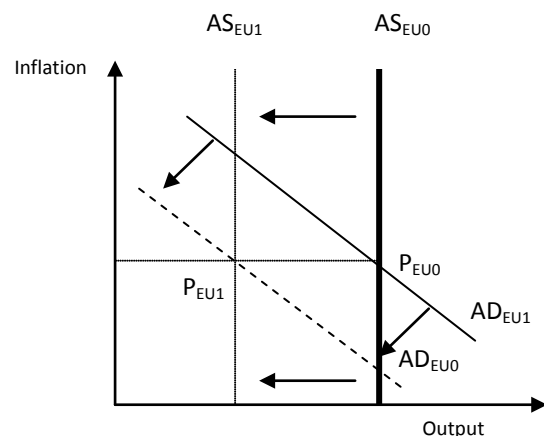

a. On a long term, the monetary policy affects the inflation rate only (nominal variables), and the fiscal policy determines the degree of indebtedness, the role and the importance of the public sector, the level and the structure of taxation (and, by means of it, the real variables).

For example, let us consider the long-term interaction between the monetary policy and the fiscal policy (in case there are two countries which are member to the Eurozone). For this analysis, we use the aggregate demand AD – the aggregate supply AS. The AS curves are vertical for both countries and they are represented at the level of the potential GDP. We are also assuming that the two countries have the curves AD and AS.

On a long term, the European Central Bank (ECB) can establish a certain level of the inflation rate for the entire area which forms the Economic and Monetary Union, without affecting the production level in neither of the countries, nor for the entire area.

In view of this target of the European Central Bank, a change in the government expenses in one of the two countries influence the relative output, the prices and the distribution of production between the public sector and the private sector, but not the level of the GDP on a long term. The occurrence of a shock upon the aggregate supply in one of the countries, as well as the increase of taxes which distorts the financial system, moves the curve AS towards the left both for that country, and also for the entire monetary union. However, the European Central Bank will react to this impulse (by increasing the interest charge), without changing the output in another country which is member to the monetary union (Von Hagen, J., Mundschenk, S., 2002). Thus, it will be able to maintain the same inflation rate without long-term consequences upon the output of another country (figure 1).

Figure 1. Common monetary policy- national fiscal policies mix on a long term

The graphical analysis shows that the European Central Bank – by means of its monetary policy – can achieve the long-term price stability, without interfering with the fiscal policy, and the national governments may choose the extent of their expenses and taxes in compliance with the national preferences. Thus, beside imposing a constraint related to the budget deficit on a

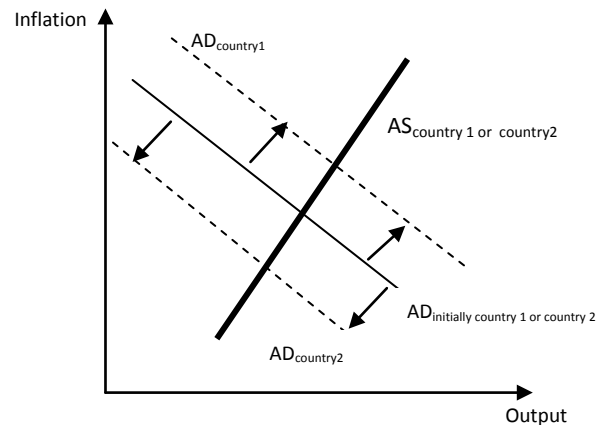

long term, the coordination between the common monetary policy and the decentralized fiscal policies of the member countries is not necessary;

b. On a short term, if the European Central Bank has the full control upon the interest charge of the monetary policy, we cannot say the same thing about other variables which provide the transmission of the monetary policy's effects – the rate of exchange or the interest charge on a long term –, which are influenced by the fiscal policy.

For example, let us consider the AD-AS model presented above. On a short term, the wages are rigid and the non-anticipated changes of the prices have effects upon the real output. The curve of the aggregate supply AS has a positive slope. The European Central Bank can determine the balance rate for the interest and the level of the aggregate demand for the entire Union.

Now, let us assume that the government of the first country wants to increase the output level by increasing the government expenses and, thus, the budget deficit. The aggregate demand will get increased in that country, as well as the aggregate demand of the entire union. Inflationary pressures will occur. ECB will increase the interest rate of monetary policy in order to settle the inflation within the target-level, thus moving the line of the aggregate demand back to the balance point. However, by increasing the interest charge, the lines of the aggregate demand for both countries will move towards the left. The aggregate demand for the entire union will remain at the same level as the initial one, but the aggregate demand is higher for the first country and lower for the second one (figure 2). Thus, we encounter a conflict between the common monetary policy, within the Union and the different fiscal policies, nationally implemented. According to the slope of the curve AS for each of the countries which are member to the Union, this interaction between policies determines the level of the aggregate demand AD for the entire Union and the way in which this aggregate demand is distributed between the two countries. The inflation rate within the Union is determined by the aggregate level of the output in balance (Von Hagen, J., Mundschenk, S., 2002).

Figure 2. The common monetary policy-national fiscal policies conflict, on a short term

The interdependences between the monetary policy and the fiscal policy are numerous on a short term (less than a year) and on a medium term (from one year up to three years). These interdependences show that the process of coordination between the monetary policy and the budget policy is necessary.

3. Solution: Policies for stimulating the aggregate supply

There is also a reform proposal with a paradigm level with reference to the importance given to the economic policies in absorbing the shocks encountered by the economy. We speak about the focusing from encouraging/restricting policies for the aggregate demand towards *policies which stimulate the aggregate supply*.

As the absence of the structural reforms is a major disturbing factor in creating an optimal policy mix, the coordination of the European economic policies should also suppose measures for the aggregate supply. We may argue this assertion with the worries encountered during the last decades of the European specialists, which have been materialized in the substantiation of the Cardiff, Luxembourg and Köln Processes, and even in the Lisbon Strategy.

It is amazing that, while the monetary and fiscal policies are sometimes conflictual in reducing the fluctuations of output and of the inflation rate, they are endlessly speculated. However, the economic theory shows that these two macroeconomic objectives can be

simultaneously reached by stimulating the aggregate supply. Even though the experience of the '70s show that using the instruments resulting in the increase of the aggregate supply does not produce miracles and that it a longer period of time is necessary so that it could show its effects, the creation of a mix including policies focusing on the supply – which improve the operability of the markets, referring to taxation, which eliminate the effects of the negative externalities, etc – would be optimal.

The main target of the policies which stimulate the aggregate supply is the increase of the potential output, by increasing the technical and allocating efficiency in distributing the resources.

Figure 3. Implementation of the policies which stimulate the aggregate supply

Economy is in balance on a short term E_0 (which meanwhile corresponds to the potential GDP at the initial moment) (figure 3). The movement of the curve AS on a short term from AS_0 to AS_1 determines the increase of the GDP and the decrease of the average price level P . Economy reaches point E_1 . The change in the aggregate supply AS on a short term also determines the movement of the line corresponding to the aggregate supply AS on a long term from $LRAS_0$ to $LRAS_1$. So, the same thing happens to the increase of the potential GDP. Thus, economy will reach the new balance point E_2 , as the aggregate demand AD will also get increased, from AD_0 to AD_1 . The level of the potential GDP will be higher,

while the average level of the prices will get decreased.

4. Conclusions and recommendations for the European model

Starting from this theoretical approach, we consider that the measures which should be taken in order to stimulate the aggregate supply in the European model are as it follows:

- diminishing the effects of the imperfect competition – by means of the common policy in the competition field;
- diminishing the commercial and protectionism barriers – by means of the common commercial policy;
- improving the efficiency of the fiscal systems by means of granting subsidies, collecting taxes, decreasing the social security contribution, etc.;
- strict settling of the property rights – by means of the *acquis communautaire*;
- cautious wage policies;
- strong budget constraints for the bad payers;
- liberalization in the field of public utilities, telecommunications, transports, etc.;
- decreasing the transaction costs.

It is praiseworthy that the European political decision makers realized that these above listed measures only do not result but in a level increase. Actually, measures should have been taken much earlier in order to accelerate the increase of the potential GDP:

- stimulating economies and investments;
- render the labor market more flexible by adopting flexible and modern labor codes;
- facilitating the access to new technologies, mobile phones and Internet;
- increase of expenses for research-development up to 3% of the GDP;
- adopting the unique European system for patenting;
- increasing the rate of employment by stimulating the initiative of the small entrepreneurs;

- professional training of the laborers by adopting the continuous learning system;
- increasing the rate of participation to labor.

As a conclusion, we may say that the success of the European model supposes an optimum mix of policies, with reference both to the aggregate demand, and also to the aggregate supply. Thus, the European dynamism, the social cohesion, the accomplishment of the unique internal market and the knowledge based society remain pure dreams.

Performance Reflecting by Creating Value in Terms of Stock Type Indicators: Market Value Added and Total Shareholders Return

Solomon Daniela Cristina
Dragomirescu Simona Elena

"Vasile Alecsandri" University of Bacău, Faculty of Economic Sciences
solomon_daniela@yahoo.com
symonna21@yahoo.com

Abstract

In addition to classical indicators used in financial analysis also occur modern performance measurement indicators that are considering the concept of value creation. With enterprise's modern performance measurement indicators is quite simple to express performance shareholders' point of view and quite difficult in terms of other business partners.

Key words: performance, financial analysis, value added.

J.E.L. classification: M41, M49.

1. Introduction

In determining the indicators of value creation the basis element is represented by *value added*, which presents multiple valences for performance's measure and evaluation.

Depending on their nature, *value creation indicators* can be classified as following [1]:

A) *Hybrid nature indicators* (such as accounting and financial ones):

- *economic profit*, respective *economic value added (Economic Value Added – EVA®)* - is a registered trademark of Stern Stewart cabinet);
- *Cash Flow Added – CVA*;
- *Internal Rate of Return*, which is identified with the *Cash Flow Return on Investment – CFROI*;

B) *Stock nature indicators*:

- *Market Value Added – MVA*;
- *Total Shareholders Return – TSR*.

Strengths and *weaknesses* of these indicators are presented in Table 1[1].

Table 1. The value creation indicators - strengths, weaknesses

Indicator	Strengths	Weaknesses
A. Hybrid nature indicators		
<i>Economic profit = Economic Value Added</i>	Simple indicator, increases the awareness of concept of average weighted capital cost	Limited to one year. Evolutions in time, difficult to assess.
<i>Cash Flow Added</i>	It is not limited to the results of a year.	Supposes complex calculations.
<i>Cash Flow Return On Investment</i>		
B. Stock nature indicators		
<i>Market Value Added</i>	Striking simplicity. Reflects the total value created and not the annual one.	Subject to volatility in capital markets. Difficult to apply to not-quoted companies.
<i>Total Shareholder Return</i>	In average on long term represents the shareholders returns.	Calculated on a too short period and is the subject to volatility in capital markets.

Source: Quiry, P., Le Fur, Y., *Pierre Vernimmen, Finance d'entreprise 2009*, p. 694

2. Market Value Added – MVA

Market value added measures the new created value and is determined as the difference between the current market value

of a company and invested capital (accounting value of capital and debt):

$$MVA = \text{Market value} - \text{Invested capital}$$

Invested capital (C_{ti}) is the sum of present value of initial capital (C_i) invested by shareholders and the present value of reinvested profits (P_{ri}).

- Market value of *listed* company constitutes the market capitalization (C_b) determined by multiplying the actions' stock course with the number of shares issued and outstanding. The calculation relationship of market value added indicator becomes:

$$MVA = C_b - C_{ti}$$

- If the company is not listed, the market value is estimated on the basis of the *present value of future flows* generated for owners.

Consequently, the difference between market value of the company and investors capitals is the price *surplus* that the *market* gives the company as a result of successes registered over time [2].

Market value added can have a:

- *positive value* and means creation of wealth for shareholders by increasing the amount of capital invested by them;
- *negative value* and means reduction in market capitalization value under the own value capitals of the company. In this case not only that there was not created wealth for shareholders but also a part of the existing wealth at the time of investment was destroyed.

Market value added has some *disadvantages* because:

- does not consider the opportunity cost of invested capital and nor the amounts distributed to shareholders;
- can only be calculated at enterprise level and not on division level.

The theory also attributes importance to the *added value market index* (I_{MVA}) determined as ratio of market value of the company, respective that market capitalization (C_b) and total invested capital (C_{ti}).

Calculation of *market value added* (MVA) for the two analyzed societies listed on Bucharest Stock Exchange is shown in Table 2.

Graphical representation of the evolution of market value added for the two analyzed societies listed on Bucharest Stock Exchange is suggestively shown in Figure 1 and the market value added index's evolution is given in Figure 2.

Figure 1. Evolution of market value added (MVA)

Figure 2. Evolution of market value added index (I_{MVA})

In 2004-2005 period, at *S.C. ALFA S.A.* is noticed that the *difference* between market capitalization and the present value of invested capital is *negative* reflecting the *destroyed market value added*.

After 2005 indicator's value increases and reaches its highest level of 7372918 lei in 2007; in the last year the market value added constricts reaching 3458568 lei due to lower market capitalization (amid stock market lower rate) and invested capital growth, particularly of reinvested profits.

In the case of *S.C. BETA S.A.*, the growth of market value added during 2004-2007 from 3116401 lei to 10945935 lei is the result of increased market capitalization (market value) at a higher rate than invested capital growth. In 2008 we witnessed a sharp decrease of market value added, due to

depreciation of the company's market value (market capitalization), compared to increase of invested capital.

The results obtained from research show the discrepancy between the positive and increasing market value added (2004-2007) and negative value added, which confirms that in reality there *exist value created for investors* in terms of evaluation by market of the stock performance.

3. Analysis of total shareholders return

Concept introduced by consultancy firm Boston Consulting Group, *total shareholders return* - TSR characterizes the *value created by the company to its shareholders* during a period of time and shows *what investors actually receive from their investment*.

The indicator is calculated as the ratio of *change of stock value action* (ΔCa) plus received *dividends per share* - DPS and *market value of action at the beginning of the period* (Ca_0):

$$TSR = \frac{\Delta Ca + DPS}{Ca_0} \cdot 100$$

where,

ΔCa = *change in stock value of the share* established through the difference between the share at end of the period (Ca_1) and the course of share at the beginning of the period (Ca_0), $\Delta Ca = Ca_1 - Ca_0$.

Boston Consulting Group reveals a close correlation manifested between *cash flow added* evolution - *internal indicator* of assessment for value created by the firm for its owners and dynamics of the *total return of shareholders* - commensurate *external indication* of this value [3].

Increase total shareholders return reflects the increased value created by enterprise which allows stimulation of current and potential investors.

Graphical representation of the evolution of the *shareholders total return* is presented in Figure 3.

Figure 3. The evolution of return rate obtained by shareholders (TSR)

The total return rate obtained by shareholders of ALFA company increases from 59,49% in 2005 to 74,61% in 2006 and reached maxim level of 138,12% in 2007, while in 2008 registered the negative value - 22,22%. The indicator's increase was the consequence of favourable change of stock course and the increase of dividends per share. The decrease of total return rate of shareholders from the last year was the consequence of the stock rate increase at the beginning of the period from 19 lei/share la 45 lei/share.

In the case of S.C. BETA S.A. shareholders total return rate has an oscillating trend: decreased from 98,21% in 2005 to 36% in 2006, then increased to 76,47% in 2007, while in 2008 the decreasing emphasized, the indicator reaching the minimum level -45%. Strong reduction in 2008 was due to the increase of stock rate per share at the beginning of the period from 34 lei / share to 60 lei per share. It appears that during 2006-2008 dividends per share have zero value since the company choose that the profit to be distributed to finance investment programs and decided not to pay dividends.

BETA shareholders *gain* in 2005 - 2007, materialized in *addition of value* obtained from the *holding of shares*, which 2005 is added and the gain in the form of *paid dividends*.

4. Conclusions

Improving financial performance of enterprises can be achieved by performing a complete and proper financial diagnosis analysis, in this sense analysis through value creation becomes essential.

Currently, the trend towards performance evaluation based on value creation, but subordinate to the desire for sustainable development is manifested. Value creation becomes the primary goal of a business that should take into account the requirements of all interest groups, to respect the environment, right to work and human dignity.

Financial Equilibrium Analysis at Firm Level

Spătariu Elena Cerasela
Epure Dănuț Tiberius
Lazăr Cristina

"Ovidius" University of Constanta, Faculty of Economic Sciences

ebarbu2001@yahoo.com

epure_dan@yahoo.com

cgrozea@yahoo.com

Abstract

A company's financial position is influenced by its own economic resources, the liquidity and the solvency of the company, its financial structure, its adaptability to environmental changes. The company's self-financing capacity represents the ability to increase the company's working capital needs, investments and reimburse the liabilities, finance some current management needs, to remunerate the invested capital.

Key words: Working capital, assets, liabilities, self-financing capacity, proceeds, expenses.

J.E.L. classification: D58

Company's ability to generate cash or cash equivalent results from its ability to pay employees, suppliers, creditors and remunerate its owners.

Underlying issues are information about the structure, performance and changes a firm's financial position. There are several factors that influence the financial position a company: economical, liquidity and solvency of the company, financial structure, its adaptability to environmental changes.

On this basis there is information about the structure, performance, modifications of the financial position of a firm. There is a series of factors influence a company's financial position: economic resources, liquidity and solvency of the company, financial structure, its adaptability to environmental changes. Information about these factors is helpful in:

- anticipation of future credit needs;
- distribution of future cash flows;

- anticipation of future funding opportunities;

- anticipating the company's possibility to honour commitments;

- evaluation of operating activities, financing and investment.

Financial balance can be defined by the company's ability to secure payment of the previously contracted liabilities without interruption, including current liabilities incurred in implementing the object of

activity, or tax law, in its collections, such that it can avoid the risk of bankruptcy. The word balance evokes the idea of harmony between the elements of a system; in finance it means the harmonization between resources and needs.

The balance reflects the financial stability of the company at a due time.

The balance is a summary document which shows the assets, liabilities and equity of the entity at the end of the year, and in other cases provided by law.

Each element of the asset is an "allocation" of money, being structured by their degree of liquidity (the ability to be converted into money). Thus, intangible assets (patents, licenses, studies, other trademarks and copyrights) are the less liquid; tangible assets (land, buildings, equipment, etc.) have a higher liquidity than the intangible assets and financial assets (debt participation, long-term loans) are the most liquid.

Due to relatively slow rotation of capital invested in such assets, they are called "permanent allocation" (stable). The asset include assets then (stocks, claims, cash availability) more liquid than property, called the "temporary allocations," where the recovery of the invested capital is made at the end of the exercise.

Permanent allocation should be generally covered by permanent sources. The difference between permanent sources and permanent allocation represents the "working capital" (WC) of the enterprise.

Working capital - is an indicator of long-term financial balance that compares the permanent sources of funding with the permanent needs, representing the level of stable sources used for funding the cyclical assets and is determined whether:

a. as a difference between the permanent capital and intangible net assets, using the relation:

$$WC = \text{Permanent Capital} - \text{net Assets}$$

b. as a difference between assets (stocks + debt + availability) and short term liabilities (financial obligations and liabilities on short term):

$$WC = \text{Assets} - \text{STL}$$

In practice the following situations may occur:

a. Increase of the working capital - a positive situation as an important part of working capital will fund assets.

It is not considered favourable the working capital that covers entirely the need of funding for assets, because the permanent resources, more expensive could be replaced by temporary resources.

b. Working capital decrease - negative situation because the assets are covered in a less measure from permanent resources.

The working capital requirement is an indicator of financial balance but on short-term, representing the part of the cyclical assets to be financed from stable sources, representing the assets with a liquidity term under a year that are supposed to be financed with maturities over one year.

Working capital requirement is calculated as follows:

$$WCR = \text{Currents Assets} - \text{Current Liabilities}$$

Or

$$WCR = [\text{Intangible assets} - \text{Liquidation}] - [\text{Short term liabilities} - \text{Treasurer Loans}]$$

IF:

a) WCR is positive there is a shortage of temporary sources as a result of some temporary needs over the cyclic sources that might be mobilized.

b) WCR is negative, then there is an excess of temporary sources to be financed

either from the working capital either from the treasury, as the result of more relaxed contracting-term debt payment or of an increase of the duration of rotation for stocks and receivables.

Net cash position is an indicator of current financial year that reflects the image of currency cash and short term investments arising from the current evolution of collection and payments or placing surplus cash.

Is calculated as:

- a difference between Working Capital (WC) and Working Capital Requirement (WCR):

$$NCP = WC - WCR$$

- a difference between the liquid assets (LA) and short term borrowings, including the bank creditor balance (STB):

$$NCP = LA - STB$$

Net cash increase is based on the increase in cash and short term investments of the company as a result of a short-term financial autonomy and financial balance on the one hand and of reducing short-term bank loans on the other hand.

Net cash decrease is the result of increased loan volume on short-term and decreasing cash investments, including the investments made by the company.

Self-financing capacity expresses in monetary terms the company's ability to develop its activity work through their own financial means. Therefore, "it reflects the financial potential of economic growth of the company, ie the financial source, generated by the industrial and commercial activity of the company after deducting all expenses payable to a certain maturity."

In other words, self-financing capacity is the ability of the firm to increase the company's working capital needs, investments and reimburse the liabilities, finance some current management needs, to remunerate the invested capital.

Given that this indicator measures the potential cash created by the company through its activity, to establish it are taken into account the proceeds that are collected and all expenses that are paid.

$$SFC = \text{Proceeds} - \text{payable Expenses.}$$

In order to calculate the self-financing capacity there are used two methods:

The deductive method - where,

$$\begin{aligned} \text{SFC} &= \text{Gross operating result} \\ &+ \text{Other operating income} \\ &- \text{Other operating expenses} \\ &+ \text{Financial income} \\ &- \text{Financial expenses} \\ &+ \text{Extraordinary income} \\ &- \text{Extraordinary expenses} \\ &- \text{Income tax.} \end{aligned}$$

The additive method

$$\text{SFC} = \text{Net Profit} - \text{Calculated Income} + \text{Calculated expenses}$$

or

$$\begin{aligned} \text{SFC} &= \text{Result for the year} \\ &+ \text{Amortizations and provisions (for} \\ &\quad \text{operational, financial, extraordinary)} \\ &- \text{Incomes from provisions (operating,} \\ &\quad \text{financial, extraordinary)} \\ &+ \text{Net book value of transferred assets} \\ &- \text{Income from sale of assets} \\ &- \text{Investment subsidies transferred to} \\ &\quad \text{the result of the exercise.} \end{aligned}$$

In an economy characterized by financial bottlenecks the self-financing capacity loses its informational value because is taken into account potential receipts and payments, cash flow analysis is recommended.

Not all resources representing the self-financing capacity will be used to finance the enterprise; next indicator can be calculated:

$$\text{Self-financing} = \text{SFC} - \text{distributed Dividends} - \text{manager's share} - \text{employees' participation to profit}$$

The size and variation of self-financing capacity is dependent on the direction of depreciation policy, tax policy and actions related to increasing profitability due to increased production volume, price, and diversification of products' portfolio.

Cash Flow Analysis Using Methods of Measuring Financial Flows by Type of Activity

Spineanu-Georgescu Luciana
"Spiru Haret" University
lspineanu@yahoo.com

Abstract

Analysis of financial balance through cash flows used to estimate future cash needs based on past situation, their knowledge would be useful to both shareholders interested in the existence of sufficient cash to pay dividends and creditors who are interested in recovering loans. Equally, knowledge of future cash flows of interest to potential investors updated cash flow method is a method of evaluation of the company.

Key words: financial balance, cash flow, treasury.

J.E.L. classification: M10,M21.

1. Introduction

Cash flow statement provides information required to analyze company's ability to generate future cash flows and cash equivalents. Cash flows derived by summing up enterprises: cash flows from operating activities, investing activities and financing activities.

Treasury economic unit occupies a central place in the economic information system, as all specific operations cycle operating, investing and financing value is expressed. Treasury is regarded as a key information and at the same time objective, because through her company secures financing activity.

Also, "Treasury entity is the bridge between the three activities delineated above and acts as a filter in flow control fundamental relationship: money-commodity-money."

Circulation merchandise trade flows provide an example of physical changes in cash flow as an intermediate stage of debt (for sale) or liabilities (the money). These key management operations, which flows

through the wick to / from cash flows undertake simultaneous and / or alternatives that balance.

Created a number of mechanisms to provide general guidance in the areas of investment that will produce the most significant results for the satisfaction of investors and ensuring growth. Accounting approach in terms of state interest (tax) and / or strict company (survival / development), it was making the problem a priority to ensure the information requirements of investors, in order to attract capital to viable and dynamic companies, from globalized world. Investment decision requires relevant and reliable information, expressed in a language generally accepted as common procedures and verified by authorized personnel.

OMFP no. 3055/2009 for the approval of accounting regulations in accordance with the IV of the Directive of European Economic Community introduced in general practice, the preparation and presentation of financial statements.

An important component of financial statements is the cash flow statement. Disclosure requirements for cash flow statement are set out in IAS 7, which states that it should provide a basis for assessing the enterprise's ability to generate cash and cash equivalents, and it needs to use those cash flows.

Judging the performance and financial position of the company based only on profit and loss account and balance sheet is not relevant because of the static information provided by these summary documents. Its primary usefulness lies in differentiating the type of picture that makes the cost-uses, payments, on the one hand and, on the other hand, income, resources, revenue.

The picture of financing allows the assessment of financial stability and long term, providing comprehensive information on changes in treasury, but does not allow an

analysis of the treasury function as a cash flow table.

Business activity is the result of numerous economic and financial transactions that affect assets of the business and expressed through the receipts and payments. Therefore, arise inflows and outflows into and from the property unit, so that changes the focus of analysis is the concept of liquid assets released or used.

Because all financial flows and make financial diagnosis is not recorded in the balance sheet or in the income statement, financial analysts have proposed the development of boards and panels fluxurazi financing cash (cash), financial flows that allow the reconstruction period.

In accounting, an important role in determining and highlighting the company's cash flow picture it has cash.

The picture of financing in general, summarizes changes in the size and composition of the financial situation and facts from operations rise environment interactions between the enterprise and its economic and social.

Under IAS 1, after considering the results account, balance sheet and changes in equity financing table analysis and cash flow is an important step in examining the documents summarizing the company's financial situation.

All financial flows through a complete diagnosis of the enterprise more dynamic and comprehensive approach, though not explicit or in balance, no account of the result. In this case, financial analysts draw pictures and paintings of financing cash flows (cash), allowing reconstruction period financial flows.

A variant of the array of financing is cash flow, required for publicly traded companies and large enterprises, according to the OMFP no. 3055/2009, which clarifies how the presentation by IAS 7, and optional for entities that apply simplified accounting regulations.

Change in net cash is what is commonly expressed by Anglo-Saxon period cash flow (cash flow), which illustrates the funds obtained by the company in last financial year on activities (operating, investing, financing), how were used and the extent to which they relied on sources other than operating.

Entering cash flows (cash) as part of annual financial statements (IAS 7), mandatory for large enterprises (OMFP no. 3055/2009) and optional for small and medium enterprises, allows a dynamic analysis of financial equilibrium, by describing the operations (operation, investment, finance) that have driven business transformation heritage.

This expresses the evolution of the company's financial position at the situation from the beginning, generating hypothetical dimension of performance, presented as the profit does not coincide with the end balance of cash at the time, only to give authenticity to good management of the company.

A picture of cash flows enables users of financial statements:

- evaluates an enterprise's ability to release cash;
- determine the liquidity needs;
- to provide maturity and the risk of future earnings;
- to compare the results of the enterprise, eliminating the effects of using different accounting methods for the same transactions and events.

The 2009 edition of IFRS highlights in particular the notion of replacing the cash flows of cash flows.

To justify the choice of cash flows, Professor Monica Petcu last paper presented three main reasons as follows:

◆ treasury dominance as an indicator of company management and analysis of bankruptcy risk. Treasury is regarded as a key indicator of current and long-term management, ensuring continuity of business operations and finance. Its content is very important information in the financial analysis, allowing short-term solvency assessment and measuring long-term financing needs;

◆ objective nature of cash flows. Unlike revolving fund whose size is strongly affected by accounting conventions, cash flows are affected by the market;

◆ adjustment panel for predictions. The enterprise budget approach, the functional structure of cash flows allow the development of cash flow projections of current business operations resulting from cyclical, while flows from investing activities and financing concerns and needs acyclic resources that depend on the medium-term

business strategy and long term.

2. The situation of cash flows

Statement of cash flows provides information about the degree to which various activities of the enterprise generates flows (surplus or deficit) of cash, these flows are structured in three categories:

- 1) Cash flows from operating activities;
- 2) Cash flows from investing activities;
- 3) Cash flows from financing activities.

Statement of cash flows (cash) and believes Treasury describes as a central variable, which is the expression of inflows and outflows of cash and equivalents, and the variation is explained by cash flows of receipts and payments made during the period. Cash receipts are affected by the + sign, and cash payments for the same activities are affected by the sign -.

While treasury business is unique, all cash flows passing through, this picture explains the contribution of each "function" on global change as the result of the summation of net cash operating cash flows ($\Delta TExp$), investments (ΔTI), financing (ΔTF):

$$\Delta TN = \Delta TExp + \Delta TI + \Delta TF$$

3. The methods for determining the financial flows

Cash flows can be determined by two methods: direct and indirect method.

The direct method deducts the payments from the proceeds of the financial year by type of activity and allows the estimation of future cash flows and total activities.

Under this method, cash flow from current activity is a key indicator of cash generation for other activities: loan repayment, maintaining operational capacity of the enterprise, pay dividends, new investments without external funding.

- the entity's accounting records;
- by adjusting sales, cost of sales (interest and similar income and interest expense and similar charges for financial institutions) and other elements in the profit and loss account:
 - changes during the period in inventories and operating receivables and payables;
 - other non-cash items;
 - other items for which the cash effects are cash flows from investing or financing.

Table no. 1 Determination of net cash flow from operating activities

The direct method
Proceeds from the sale of goods, services
+Cash receipts from royalties, fees, commissions and other income
+ Interest Proceeds
+ Other operating revenue related
-Cash payments made to suppliers of goods and service
-Cash payments made to and on behalf of employees
-VAT Payments
-Payments on interest and dividends
-Income tax payments (which do not meet the investment and financing activities)
-Other payments for operating
± Extraordinary Items
= Net cash flow from operating activities

Streams of earnings or dividends or interest payments may be included in the cash flows related to financing activities.

Extraordinary cash flows for the items to be presented separately to provide information to users on their contribution to cash flows from the economic unit.

Cash flows from investments reflects the extent that the expenditure generated resources that will produce revenues in future (buildings, equipment).

The separate disclosure of cash flow from investment activity is important because the cash flows represent the extent to which expenditures have been aimed at obtaining resources to generate future revenues and cash flows.

How to determine, according to the examples offered by IAS 7 Net cash flow for investment activity is:

Table no. 2 Determination of net cash flow from investing activities

The direct method
-Acquisition of subsidiary X(-)purchased treasury
+ Y branch assignment
- Acquisition of property
- Purchase of investment securities
+ Proceeds from sale of property
+Proceeds from sale of investment securities
+ Interest received
+ Dividends received
= Net cash flow from investing activities

Cash flows from financing activities allow estimating future demand cash flows from the financing company (receipt or repayment of loans, proceeds from issue of securities issued redemption payments, receipts or lease payments).

Financing activity is that activity which causes changes in the size and structure equity and capital impumutate of the economic entity.

Scheme cash flows from financing activities shows sources of external funding which has made the firm (capital increase through cash or loans), if the cash flows arising from ordinary activities was insufficient to cover investment operations.

With the examples presented in Annex standard IAS 7 the following table can be developed for determining net cash flow from financing activities.

Table no. 3 Determination of net cash flow from financing activities

+ cash capital increases
- cash capital repayments
+ show / borrowing (bonds, bank, etc. - excluding cash)
- Repayment of loans (bonds, bank, etc. excluding cash)
- Repayment of debt related to finance leases
- Interest and dividends paid
= Net cash flow from financing activities

A second method of determining cash flow, indirect method is based on profit / net loss, adjusted for transactions such as money, the liabilities, items of income and expense cash flows associated with investing or financing.

OMFP no. 3055/2009 makes provision that the cash flows from operating activities can be presented using the indirect method by showing the revenues and expenditures recorded in the income statement and the changes occurring during the period in inventories and receivables and payables operation.

Table no. 4 Determination of net cash flow from financing activities under the indirect method

± The result before tax and extraordinary items (Elimination of non-monetary items)
+Expenses for depreciation and provisions
-Income from provisions (Remove items not related to the operation)
± result from the sale of assets
± result from the sale of investment securities
+ Interest expense
- Interest and dividends
- Investment subsidies transferred to income
= Operating result before changes in working capital requirements
± Changes in inventories
± Change in accounts receivables from customers and other operating
± Change in accounts and other debt providers operating
± Change in prepaid expenses
± Change in deferred income
- Interest and dividends paid
- Income tax payments (which do not meet the investment and financing activities)
± Extraordinary Items
= Net cash flow from operating activities

Under the indirect method, cash flow modeling for investing activities and financing is similar to that described for the direct method.

Separate Representation cash flows reflect increases in operating capacity and cash flow required to maintain operating capacity is useful in enabling users to determine if the enterprise is investing adequately to maintain its operating capacity. An enterprise that does not invest adequately in the maintenance of its operating capacity may damage future profitability for the current liquidity and distributions to shareholders.

Introducing the segment cash flows enables users to obtain a better understanding of the relationship between cash flows of the company in general and those of its component parts, on the one hand, and the degree of availability and variability of flows treasury segments on the other hand.

Analysis of Financial Position Based on the Balance Sheet

Spineanu-Georgescu Luciana
"Spiru Haret" University
lspineanu@yahoo.com

Abstract

Analysis of financial position based on the balance sheet is mainly aimed at assessing the extent to which financial structure chosen by the firm, namely, financial resources, covering the needs reflected in the balance sheet financed. This is done through an analysis known as horizontal analysis balance sheet financial imbalances.

Key words: account, balance sheet, current assets, current bank loans.

J.E.L. classification: M10,M21.

1. Introduction

Achieving financial balance analysis must be preceded by processing operation of the balance sheet as a list, the balance sheet with asset and liability positions opposite each other in the form of account.

Of asset arrangement is made in ascending order of their liquidity and liability items in the balance sheet is structured in ascending order of their chargeability.

The asset will be included in the first place, the less liquid items, ie assets that form the group always needs to be financed. Then comes the assets, which have a higher degree of liquidity of the former group was funded temporary needs.

Presentation of the financial position of the company balance sheet is in compliance with specific accounting rules designed to ensure an accurate picture of it. As a result, this tool has some shortcomings arising from:

- the conventional accounting;
- distortion of the legal and economic reality;
- subjectivity of information;
- the incidence of taxation.

Financial analysts recommended that the financial statement presentation and analysis of financial and economic enterprise.

Regulations specific to the underlying financial concerns the balance sheet optics primacy of economic evaluation and financial and economic elements, as such, registration and evaluation of all assets and liabilities balance sheet (resources) available for undertaking the activity, regardless of legal status ownership of assets and the importance of compliance with the criteria of liquidity and chargeability.

According to these criteria:

- ◆ assets are structured in order of liquidity:
 - fixed assets (AI), which comprise all liquid assets of more than one year;
 - assets (AC), containing all the liquid assets of less than one year;
- ◆ resources are grouped according to which payment:
 - debts that must be paid within a period of up to one year (DTS)
 - debts that must be paid within a period longer than one year (DTML)
 - capital and reserves (C).

Preparation of financial accounts is driven by the format required by the the OMFP no. 3055/2009 which provides short-term debt delimiting the medium and long term, regardless of resources, subject to reclassification and restatement of certain elements.

The reclassification and restatement of balance sheet items to determine whether the structure of their assets (on which the company has achieved a certain performance) and liabilities (financial structure which supports the entire process).

Reclassification of balance sheet items:

- diminishing asset immobilized with fictitious assets (up costs, research and development expenses may not materialize), modifying counterpart resources;

- financial assets include cash within less than a year in short-term investment and vice versa;
- including greater liquidity of claims a year on fixed assets;
- inclusion in the claims settlement advances to the company, given the need for their settlement;
- allocation of deferred or capitalized as an asset or assets in debt in their liquidity;
- deferred income inclusion into debt with higher chargeability than one year or, where appropriate;
- inclusion in net capital investment grants of land and related assets received free of charge, taxes are included in debt related. Eliminating subsidies for investments of patents, trademarks received free of charge (considered in this approach as fictitious assets) in consideration of the intangibles, the amounts allocated from the budget to finance these elements;
- exclusion of capital subscribed and paid up capital, and in consideration of claims, settlements capital associations;
- the inclusion of provisions for risks and charges are in debt to be paid within a period up to one year or in debt to be paid within a period exceeding one year, depending on which payment;
- treatment group loans, debt that the parent or another subsidiary as capital items, was taken into account in determining the financial profitability of the group. In terms of solvency, the analysis distinguishes between capital and stable nature, which include debt and equity granted permanent manner in the short term, including short-term debt within the group and not included in the permanent resources;
- treating current accounts as equity partners, given the arguments for taking them into account when calculating the financial return, either mandating their inclusion in the permanent resources or the current resources, depending on their chargeability

Restatement of financial-economic elements:

- location and operating leases allow the company to use an asset without advance purchase value. From a legal perspective, not the owner of the property company, not an asset will be recorded in its accounting and, accordingly, fees and operating lease rates to be paid are not identified as sources of funding. Analysis of financial balance is achieved by confronting successive groups of those in the financial balance sheet liability side, comparison of several indicators that are generated for the study of classical balance, such as working capital (FR), working capital requirements (NFR) and net Treasury (TN).

2. The classic indicators for determining the financial balance

Working capital surplus resulting from the comparison is greater than the permanent resources necessary to finance the company permanently. This surplus of resources released by the permanent financing of the property cycle may be used and run for reannoirea current assets. Therefore, the revolving fund is a financial safety margin that allows the company to bear, without difficulty, various short-term risks.

Indicator revolving fund may have several forms, such distinction is made between gross working capital, net working capital, fund its working capital and foreign working capital.

Gross Working Capital Fund (FR_B) or total working capital likely review all assets to be converted into cash within a period of less than one year (temporary needs). For this reason, you might say that any time a company has a revolving fund.

Net Working Capital Fund (FR_N) or permanent is the most important in terms of long-term financial stability analysis. He is the permanent resources (R_P) after finance the remaining permanent (N_P), respectively, permanent capital surplus (CP) remained after the financing of fixed assets Net (A_{IN}). Relationship of net working capital calculation is:

$$FR_N = R_P - N_P = CP - A_{IN}$$

Depending on the size of the two factors that determine net working capital, the indicator can be positive, negative or zero:

$FR_N > 0$ which results $CP > A_{IN}$, positive working capital means more safety margin of the company, because an increasing share of current assets will be financed with permanent capital remaining after covering permanent needs.

$FR_N = 0$ which results $CP = A_{IN}$, zero working capital is the perfect shape of harmonization with the necessary resources to finance permanent, which is not really feasible in the long term.

$FR_N < 0$ which results $CP < A_{IN}$, shows a negative working capital to finance the ongoing lack of resources constantly, which means that part of the property is financed by current liabilities, and that does not reflect always a financial imbalance.

Causes a negative working capital may be declining: the effect of increasing net fixed asset investment, in which long-term hopes for a positive working capital due to increasing economic profitability as a result of investment operations, reducing permanent capital or the repayment of debentures, those received from banks or other specialized financial institutions, with positive effect on firm financial autonomy, either from capital reduction, with a negative effect on the possibility of contracting new loans.

An alternative definition of net working capital is obtained from comparing the two groups at the bottom of the balance sheet, that needs temporary (N_T) with temporary resources (R_T).

$$FR_N = N_T - R_T = A_C - D_C$$

Working capital facility (FR_{pr}) is economic autonomy of the unit in investment financing. The indicator can be determined as the difference between equity (C_{pr}) and need permanent (net assets) or the difference between working capital and net debt to be paid within a period exceeding one year.

$$FR_{pr} = C_{pr} - N_P = C_{pr} - A_{in}$$

Working capital reveals its influence on how the financing structure of the constitution, ie the extent to which financial balance is achieved through equity, which reflects the degree of financial autonomy of the enterprise.

Revolving loan fund (foreign) reflects long-term indebtedness to finance short-term needs.

According to some specialists working capital requirements (NFR) is the most important indicator for financial stability analysis, because it has the structure of current assets and liabilities and liquidity ratio / chargeability of them.

Working capital requirement is calculated as the difference between cyclical needs (current assets less availability) and cyclic resources (debt less than 1 year of current bank loans).

Cyclical needs = needs temporary (Current assets - Cash and bank accounts) + expenses in advance

Temporary cyclical resources = resources = (debts to be paid within a period of one year - current bank loans) + Deferred income.

$$NFR = (\text{Receivables} + \text{Inventories} + \text{prepaid expenses}) - (\text{short-term debts} - \text{current bank loans} + \text{Deferred income})$$

If $NFR > 0$, results in a temporary surplus to need temporary resources can be mobilized.

This is a normal situation where the consequence of the increasing demand for investment financing the operating cycle.

Otherwise, show a negative gap between inventory and liquidation of claims and liability for the debt service for the purposes of slowing revenue and accelerate payments, which will affect the ability to pay.

An $NFR < 0$, is a temporary net surplus of resources to capital assets, being smaller than the temporary needs of temporary resources can be mobilized.

This situation is favorable if the consequence of the rotation speed of current assets, to expedite payment receipts and relaxation, with favorable effects on ability to pay.

Net Treasury (TN) comes from the equal balance between assets and liabilities, tabular presentation of meaning in Active = Passive, that uses = resources, leading to equal comparison of the revolving fund (FR) to fund working capital requirements (NFR). Defined as cash surplus derived from business activity, net treasury (TN), is determined as the difference between net working capital and working capital requirements:

$$TN = FR_N - NFR$$

After comparing previous results overall financial balance of the company, which is a result of all transactions affecting the balance sheet items and that results from horizontal analysis balance sheet presented in table form, can be determined in two ways:

a) Based on the upper part of the balance sheet:

$$TN = FR - NFR$$

b) Based on the lower part of the balance sheet:

$TN = \text{Cash and bank accounts} - \text{Short-term bank loans}$

Or

$TN = \text{Active treasury} - \text{Treasury passive}$

where:

Treasury is actively released from function area current availability enterprise plus redeemable at any time investments (investment securities).

Treasury comprises passive short-term bank loans, credit balances with banks and expected effects (off-balance), interest on short-term bank loans.

The positive or negative net cash inequality is the result of working capital and working capital needs, which may explain the following cases:

a) If $TN > 0$, is the expression of established financial balance across the enterprise activities and the outcome of a financial year that ended with a surplus of cash availability.

It follows that $FR > NFR$ and that $\text{Cash} > \text{Current bank loans}$ in the following situations:

$FR > 0$ and $NFR > 0$, in which NFR is financed entirely from the permanent resources ($FR > 0$) and a "enrichment" of the Treasury, which allows the holding company liquidity to cover short-term bank loans or make investments of ;

$FR > 0$ and $NFR < 0$, very favorable position because the company has a surplus of funds in excess of permanent and temporary resources, the effect of performance management operating cycle, resulting in a net cash positive. The only problem with the finance manager for such an undertaking is the best way to find the placement of excess cash and maintaining a cash balance close to zero;

$FR < 0$ and $NFR < 0$, a situation common in the big distribution companies, where resources cover an operating surplus increased availability and only one part of a fixed asset which generates positive net cash.

b) If $TN < 0$, negative net treasury highlights a worrying situation in relation to overall financial balance of the company, which means the impossibility of financing working capital requirements of financial standing.

$FR < NFR$ and that $\text{Cash} < \text{Loans cash}$ following situations:

$FR > 0$ and $NFR > 0$, when the NFR is partly funded permanent capital ($FR > 0$) and partly from bank loans higher than the current liquidity, which requires current bank risk analysis.

$FR < 0$ and $NFR > 0$, the situation is critical because the economic unit and a negative working capital necessary to fund working capital, financed by both short-term bank loans. In the long run, such a situation can not be accepted as the firm enters into default and bankruptcy risk;

$FR < 0$ and $NFR < 0$, the permanent resources cover only a part of the assets restrained ($FR < 0$), the rest being covered by short-term loans (suppliers, customer advances) and current bank loans, which must review the financing structure , is increased risk of external financial dependence with a relatively high financial leverage, the treasury being negative.

Practice shows that in most cases, the onset of recovery and bankruptcy proceedings were originally business cash difficulties. Lack of cash is a constant source of risks to the enterprise and unfettered risk of lack of cash is reflected negatively on business profitability. However, there are situations where, because of gaps on the one hand, the recording and accounting of revenue and expenditure, on the other hand, their maturity as receipts and payments, a company ends its financial year have negative cash profitably.

Net cash analysis requires great caution, since its level (positive or negative) at a given moment is irrelevant. Treasury is an indicator that vary greatly within very short time.

Rising Wage Inequality in India: a Translog Cost Function Analysis

Srivastava Archana
Indian Institute of Technology, Kanpur, India
archanas@iitk.ac.in

Abstract

The paper attempts to investigate the various determinants of rising wage inequality in India since 1980s. A translog cost function along with the share equations is used to evaluate the impact of various factors such as trade, technology, liberalization phase, efficiency (technical, allocative and cost) and inflation on rising wage inequality between the skilled and unskilled labour. Seemingly unrelated regressions (SUR) procedure by Zellner is used for the estimation purpose. Annual Survey of Industries data at the two digit level from the year 1973-74 to 2007-08, has been used for the study. The findings reveal that trade and technology both tend to increase the wage inequality. Further, elasticity results reveal that capital, skilled labour, unskilled labour etc have turned out to be, substitutes since 1989, although few of them were complementary before the liberalisation phase.

Key words: Translog Cost Function, Seemingly Unrelated Regressions, Wage Inequality, Trade, Efficiency

J.E.L. classification: D24, F16, J31, O1

1. Introduction

There has been a remarkable shift in the India's foreign trade structure during the last few decades. India has been an exporter of agricultural raw materials and agro based manufactured products during the initial years after independence but because of governments' policy of heavy

Industrialisation, India is now major exporter of non agricultural products as well as of services.

Indian exports now comprises of mainly engineering and textile products, precious stones, petroleum products, jewellery, sugar, steel chemicals, zinc and leather products.

India also exports services to several countries, primarily to the US. In fact, India is among the world's largest exporters of services related to information and communication technology (ICT). It is also the key destination for business process outsourcing (BPO). India's major imports comprise of crude oil, machinery, military products, fertilizers, chemicals, gems, antiques and artworks. The acceleration of trade would suggest reforms had a major effect on India's pattern of trade. India's export share of Asia has increased from 38.7% in 2001 to 51.7% in 2008 and the share of North America has gone down to 13.5% in 2008 from 22.4% in 2001. This proves that the direction of exports is moving towards southern countries. The leading export markets for India are USA, UAE, China, Singapore and UK while the leading import sources are China, USA, Saudi Arabia, UAE and Iran.

But on the other side of this glorious picture, one can see a particular trend in wage inequality since 1980s. The pertinent question is whether one can attribute this rising wage inequality to liberalization. This paper looks into the later. Following graph, prepared taking the data from Annual Survey of Industries shows the increased wage inequality since 1980s:

The graph shows rising wage inequality between wage rate of skilled labour and wage rate of unskilled labour. We see a sharp rise in wage inequality between the both, during 1989 onwards. To look into the reasons for this is an issue for discussion and research.

The paper intends to study the impact of trade, technology and liberalization on rising wage inequality in India. The paper also attempts to have a look at different efficiency measures such as cost efficiency, allocative efficiency and technical efficiency and their impact on cost share of skilled and unskilled labour.

2. Literature review

Feenstra (2000) explained the effect of trade or technology on wages and employment. It was measured by estimating demand for skilled and unskilled labour through the translog functional form along with the share equations. The cost function includes structural variables (includes expenditures on computers and newly imported intermediate inputs etc). The result shows that trade in intermediate inputs (outsourcing) as well as computer use both explain a shift towards skilled labour in united states during the 80s, with the exact contribution of each being sensitive to how computer use is measured (i.e. as a share of capital stock or as an investment).

Another paper by K.V. Ramaswamy (2008) investigates the question of wage inequality in Indian Manufacturing in the years pertaining to trade and investment liberalisation. The objective of the paper was to test the hypothesis of skill based technological change (SBTC) due to capital-skill complementarity and the impact of labour regulations on wage inequality between skilled and unskilled labour. The skill-wage bill share equation is estimated for a panel of 46 three-digit industries spanning the period 1981-2004 followed by 113 four-digit industries panel covering the period 1993 to 2004. The econometric results suggest the positive contribution of capital-output ratio and contract worker intensity to wage inequality in Indian manufacturing.

Ali M. Khalil (2005), in his paper on pulp and paper industry using the translog cost function along with the share equation shows that the industry operates at slightly

increasing returns to capital utilisation and labour and energy are complements in production whereas materials is a substitute in production for other inputs. Technological progress generated 0.037% reduction in annual operating costs at the mean but the effect was asymmetric with a much larger impact during early part of the period.

Raghbendra Jha and Balbir Sahni (1994) in examined the trends in allocative efficiency over the period 1960-1961 to 1986-1987 in seven Indian industries, namely refining and manufacture of sugar; petroleum refining; manufacture of chemicals; fertilizers and pesticides locomotives and parts; locomotives; and cotton textiles. The translog cost function incorporating biased technical change was used again along with the share equations and Allen's partial elasticity of substitution has also been worked out. It is discovered that allocative inefficiency has been non zero in each industry for every year. Allocative inefficiency has not declined over time in those industries where prices are administered, whereas in industries where prices are not administered it has. Industries that are predominantly in the public sector are not necessarily characterized by greater allocative inefficiency than those that are predominantly in the private sector.

The paper on trade liberalisation and wage inequality by Prachi Mishra and Utsav Kumar (2005) also investigates the effect of trade policy on wages in Indian manufacturing industries in the last two decades. The results suggest the significant relationship between trade policy and industry premiums. The increasing protection in the sector lowers wages in that sector. In sectors with largest tariff reduction, wages increased relative to the economy wide average.

The paper by Rubiana Chamarbagwala and Gunjan Sharma (2000) investigates the role of Industrial Deregulation and skill upgrading on wage inequality in India. The results indicate that industrial delicensing benefitted skilled labour via capital and output skill complementarities before India liberalised trade and investment. Thus much of the increase in demand for and returns to skill as a result of capital and output-skill complementarities, can be attributed to

domestic rather than external sector reforms in India.

Bin Xu and Wei Lu in their paper on trade, technology and china's rising skill demand, using a sample of 1500 firms found that export expansion had a negative direct effect (Heckscher-Ohlin type) and a positive indirect effect (export induced skill biased technical change) on skill demand; leading to have a positive change of 5% on skilled labour demand of sample firms. In case of technical change, the foreign owned firms experienced skill biased technical progress.

3. Objectives

- To find out the reasons for rising wage inequality in India.
- To study the impact of trade, technology, liberalisation phase on wage inequality in India.
- To study the impact of cost efficiency, allocative efficiency and technical efficiency on wage inequality in India.

4. Hypothesis

- Trade has led to reduction in wage inequality between skilled and unskilled labour (Stolper Samuelson Theorem).
- Technology has helped in generating the demand for skilled workers, and in widening the skill wage gap.
- Liberalisation has led to widening the wage gap between the skilled and unskilled labour.
- Allocative as well as technical efficiency both have contributed towards the increased demand for skilled labour.

5. Data sources

The data for industries output as well as for inputs have been taken from Annual Survey of Industries, published by the Central Statistical Organization (CSO), Government of India. The *Economic and Political Weekly* has created a systematic, electronic database using ASI results for the period 1973-74 to 2003-04 (hereafter, EPW database). This contains two digit and four

digit industry level data and covers all registered factories with more than ten workers. ASI-EPW volume II presents a consistent series based on NIC-1998 at the 2-digit and 3-digit level of aggregation. We have used two digit level data for our analysis.

6. Methodology

We have started with the two digit data from Annual Survey of Industries. Here we have taken total of all Industries from the two digit Industry group from the year 1973-74 to 2007-08. We have taken cost as a function of wages of skilled labour, wages of unskilled labour, capital, output and technology. For estimating impact of technology on wage inequality we have taken translog cost function along with the share equation as given:

$$C = f(Wsk, Wusk, Pk, O, t) \dots \dots \dots (1)$$

Where C is total variable cost, Wsk and $Wusk$ are the prices of variable inputs, namely, skilled and unskilled labour, Pk is the price of capital and O is real output. The equation in (1) is assumed to take the translog function:

$$\begin{aligned} \ln C = & a_o + a_o \ln O + a_k \ln Pk + a_{sk} \ln Wsk \\ & + a_{usk} \ln Wusk + a_t t + 0.5 b_{oo} (\ln O)^2 + \\ & b_{ok} (\ln O \ln Pk) + b_{osk} (\ln O \ln Wsk) + b_{ousk} \\ & (\ln O \ln Wusk) + b_{ot} (\ln O t) + 0.5 b_{kk} (\ln Pk)^2 \\ & + b_{ksk} (\ln Pk \ln Wsk) + b_{kus} (\ln Pk \ln Wusk) \\ & + b_{kt} (\ln k t) + 0.5 b_{sksk} (\ln Wsk)^2 + b_{skusk} \\ & (\ln Wsk \ln Wusk) + b_{skt} (\ln Wsk t) + 0.5 b_{uskusk} \\ & (\ln Wusk)^2 + b_{usk} (\ln Wusk t) + 0.5 b_{tt} (tt)^2 \dots (2) \end{aligned}$$

The link between cost function parameters and factor demands is given by Shepherd Lemma. If cost is given as:

$$C = S_{sk} P_{sk} + U_{sk} P_{usk} + KP_k \dots \dots \dots (3)$$

Where S_{sk} denote demand for factor input skilled labour, given skilled labour price P_{sk} , $U_{sk} P_{usk}$ denote demand for unskilled labour,

given price of unskilled labour denoted by P_{usk} and K is the demand for capital, given price of capital denoted by P_k . Now differentiating, cost function with respect to price of skilled labour gives the share equation,

$$\partial C / \partial P_{sk} = S_k$$

Properties of Cost Functions:

Homogeneity: Homogeneous of degree one in factor prices. With the symmetry restrictions imposed on (β_{jk}) , the homogeneity conditions can be expressed as:

$$\begin{aligned} \alpha_k + \alpha_{sk} + \alpha_{usk} &= 1 \\ \beta_{ksk} + \beta_{sksk} + \beta_{skusk} &= 0 \\ \beta_{kusk} + \beta_{skusk} + \beta_{uskusk} &= 0 \\ \beta_{kk} + \beta_{ksk} + \beta_{kusk} &= 0 \end{aligned}$$

Monotonicity: Non decreasing in factor prices.

Concavity: It requires the Hessian (matrix of second order derivatives be negative) of a cost function C be negative semi definite (Berndt and Wood 1975).

Putting the restrictions and after adding an error term, the equations can be estimated by the OLS technique. Such estimates are consistent, however generally not as efficient as the SUR method, which amounts to generalized least squares (GLS). The seemingly unrelated regressions (SUR) as proposed by Arnold Zellner in (1962), is a generalization of a linear regression model that consists of several regression equations, each having its own dependent variable and potentially different sets of exogenous explanatory variables. SURE is seemingly unrelated because of correlations in the error structures. Two important cases when SUR is in fact equivalent to OLS, are: either when the error terms are in fact uncorrelated between the equations (so that they are truly unrelated), or when each equation contains exactly the same set of regressors on the right-hand-side.

Finally, we calculate elasticities of substitution to find out how it has changed the scenario of demand for skilled and unskilled labor and contributed to wage inequality. One can measure the curvature of the isoquant by estimating Allen's and

Moritima's partial elasticities of substitution. By Shepherd duality, we can get ASE from estimated parameters of cost function and fitted estimated cost share of inputs as follows,

$$\begin{aligned} \sigma_{jk} &= \frac{\beta_{jk} + S_{jk}}{S_{jk}} ; \\ \sigma_{jj} &= \frac{\beta_{jj} + S_j^2 - S_j}{S_j^2} \end{aligned}$$

Where:

- $\sigma_{ij} > 0 \rightarrow$ the factors are substitutes
- $\sigma_{ij} < 0 \rightarrow$ the factors are complements
- $\sigma_{ij} = 0 \rightarrow$ the factors have no relationship

Here β_{jk} represent the estimated second order derivatives on the diagonal of Hessian matrix. S_j and S_k represent fitted cost share of inputs (Christensen, et al. 1971), (Diewert 1971), (Uzawa 1962). The own and cross factor price elasticities of substitution are defined as:

$$\varepsilon_{jk} = \frac{\beta_{jk} + S_j S_k}{S_j} ; \quad \varepsilon_{jj} = \frac{\beta_{jj} + S_j^2 - S_j}{S_j}$$

The moritima elasticities of substitution (MES) are defined as:

$$M_{jk} = \varepsilon_{kj} - \varepsilon_{jj}$$

Where ε_{kj} and ε_{jj} are cross and own price elasticities of substitution. The moritima elasticity estimate show that how the ratio of one input to the other input respond to the change in the first input.

7. Results and discussion

The results of translog cost function along with the share equations shows that R-square has come out to be very high for cost function as well as the share equations. The result of translog function reveals that skilled labor along with other factors decreases cost., while unskilled labor along with other factors increases cost. Thus, unskilled labor along with skilled labor is necessary.

The regression results of share equations reveal that skilled labor along with technology increases skilled labor share while unskilled labor along with technology reduces unskilled labor share.

Further, results of multivariate regression, when skilled labor share is taken as dependent variable and manufacturing trade, liberalization phase, inflation and cost

efficiency are taken as independent variables show that manufacturing trade increases skilled labor share while when unskilled labor share was taken as dependent variable, it showed that it reduces unskilled labor share. This shows that trade is promoting skilled labor and contributing toward wage inequality.

Again same kind of multivariate regression is run, only replacing cost efficiency with allocative efficiency shows that allocative efficiency decreases skilled labor as well as unskilled labor share. This shows that optimal allocation of resources is required given factor price in Indian Industries.

Finally, replacing allocative efficiency with technical efficiency and taking other variables same as above reveal that technical efficiency increases unskilled labor share.

When liberalization phase, overall efficiency, manufacturing trade and interactive term of technology with overall efficiency, allocative efficiency and technical efficiency and of manufacturing trade also with all three types of efficiency were run one by one, the results show that manufacturing trade with overall efficiency reduces skilled labor share and increases unskilled labor share.

Further, technology along with technical efficiency increases wage inequality and manufacturing trade along with technical efficiency reduces wage inequality. Similar results were found with allocative efficiency.

The Allen's partial elasticity results show that capital and skilled labor are substitutes while capital and unskilled labor were complementary and turn out to be substitutes after liberalization phase. Skilled and unskilled labor is proved to be substitutes.

The results of Moritima elasticity of substitution are same as of Allen's elasticity of substitution. Therefore, change in the price of one input highly affects the demand for the other input so they are not constraints for each other.

8. Conclusion

Finally we can conclude that technology as well as trade helps in increasing wage inequality. Technology when interacts with efficiency again increases wage inequality. And trade when interacts with efficiency

helps to reduce wage inequality. Thus, trade which promotes any kind of efficiency should be promoted.

Creating a Teamwork – based Culture in Romanian Organizations

Stan Ștefania Anca
„Vasile Alecsandri” University of Bacau
anca_stan68@yahoo.com

Abstract

Customers, competition and change have created a new world of business and is becoming increasingly clear that organizations designed to operate in an environment can not only be adjusted to work well in another. One of the most challenging work cultures for an organization is an authentic teamwork – based environment. Changes in the structure of the Romanian companies call for a focus on teams, because they are able to assume continuity, flexibility and long – lasting performance.

Developing a team requires hard work and responsibility lies with the organization, manager or team leader, and each team member.

Key words: hierarchical structure, flexibility, teamwork, team leader

J.E.L. classification: M 59

For an organization to change from a traditional classical structure to an organic team – based structure requires changes not only in structure, but in processes, systems, attitudes, leadership, philosophy and style.

1. The team and the organization

Many Romanian organizations today operate hierarchically with an autocratic management style. This impedes team success because the existing culture will not support team development. Organizations mired in bureaucracy are slow to respond to environment changes. One of the most challenging work cultures for an organization is an authentic teamwork based environment.

Today's organization must be more flexible, creative, and innovative in meeting the challenges of declining productivity, increasing competition and motivating unique and diverse work force. To foster a

productive and satisfied staff, managers are increasingly involving employees in decision making and personal strategies.

Changes in the structure of the Romanian companies call for a focus on teams, because they are able to assume continuity, flexibility and long – lasting performance.

Team in organization are specialized form of work – groups which are characterized by strong interdependence, autonomy and shared responsibilities. Teams are the basic unit of performance in any organization. In any situation requiring a real-time combination of multiple knowledge and skills, teams inevitably get better results than some people with restrictive roles and responsibilities. Teams are more flexible than a larger group, being easily formed, developed, refocused and dismantled. Teams and performance are an unbeatable combination.[1]

The advantage of teamwork is significant productivity growth in the spheres that require creative solving of different tasks, a high degree of adaptability and operational management. Teamwork is not an answer to all company problems and organizational changes usually require interventions at all levels within an enterprise. If a company decides to introduce teamwork, this needs to be integrated into the entire organizational structure of the enterprise and this structure needs to be adapted to the new model, otherwise the effectiveness of teamwork is lost.

One of the keys to developing high performing teams is to remember that successful teams do not simply happen. They take much effort and time.

Teams function better in an organizational culture that encourages high performance by following these principles:[2]

✓ Teamwork is characterized by a set of flexible and adaptive behaviors, cognitions, and attitudes. This principle suggests team members actively gather and

capitalize on information from their environment to adaptively alter what they are doing, thinking, and feeling. Teamwork was defined as the mechanism by which members are able to adapt and adjust the timing of action in order to meet the demands of other team members, thereby resulting in coordinated, synchronized collective action.

✓ Effective teamwork requires members to engage in backup behavior. This principle suggests team members must have the willingness, capability, and preparedness to assume the duties of their fellow teammates. Teams that successfully engage in backup behavior will achieve a level of performance greater than the sum of its individual members. Information derived from mutual performance monitoring and environmental scanning drives the dynamic reallocation of resources and functions.

✓ Teamwork requires the coordination of collective interdependent team member behavior. Team coordination can be defined as the process by which team resources, activities and responses are organized to ensure that tasks are integrated, synchronized and completed within established temporal constraints. Coordination facilitates a team's capability to maintain high levels of performance, even when subjected to high levels of workload and stress. Implicit coordination occurs when team members dynamically reallocate resources among one another without being primed to do so by action plans or in reaction to explicit requests.

✓ Teamwork requires team members to actively manage conflict to create and maintain harmonious interpersonal and interteam relationships. Every team member must make a concerted effort to contribute to the collective social system within which team members operate. Team members must consciously manage interpersonal relationships because good relations can prompt the voicing of concerns, the giving of feedback, and the implementation of change. Interpersonal relations are defined as a team's ability to optimize the quality of team members interactions through resolution of dissent, utilization of cooperative behaviors, or the use of motivational reinforcing statements.

Successful teams effectively turn strategy and goals into tangible actions and results. They make decisions more rapidly and create support for their decisions in the wider organization. They adapt faster to changing market conditions or to changes in their organization. This obviously leads to better results.

When team work, they represent the best proven way to convert embryonic visions and values into consistent action pattern because they rely on people working to develop a shared sense of direction among people throughout an organization. Teams can make hierarchy responsive without weakening it, energize processes across organizational boundaries, and bring multiple capabilities bear on difficult issues.

In conclusion, companies need to understand the power of teams. Organizational team leaders need to be nurtured and equipped to build teamwork and team efficiency.

Organizations need teams to:[3]

- Socialize new members through shared norms and values
- Facilitate sharing of knowledge through the grape vine
- Implement new policies and systems through project teams
- Improve individual performance through task specialization
- Increase operational flexibility through job rotation.

Teams need organizations too:

- To provide necessary resources through budgets
- To provide attractive working environments through job design
- To provide purpose and direction through policy and leadership
- To learn and improve themselves through feedback.

2. Creating and managing teams

Customer, competition and change have created a new world of business and is becoming increasingly clear that organizations designed to operate in an environment can not only be adjusted to work well in another. Organizational form most recent issue accordingly and at the same time reducing the number of hierarchical levels in the organizational structure and

management practice is the team. Teamwork can be viewed as an attempt to realign the modern rationality of individual motivation in the organizational motivation. Create an environment based on teamwork and effective teams is a challenge for any company. Developing a team requires hard work and responsibility lies with the organization, manager or team leader and each team member.

We believe that for most of Romanian companies is necessary to implement fundamental changes in the value system and management, thus ensuring the conditions necessary for enhancing business performance. In Romanian companies the pyramid organizational structure is the most frequent type of structure and emphasizes the high level of the power distance.

In response to international competition and the accelerating pace of technological and market change, Romanian organization gave attempted to become more flexible and adaptable. One way to do this is to push decision making down the organizational hierarchy, assigning the freedom and responsibility to respond to threats and opportunities to the work teams.

But, resistance to change is inevitable. The very structure of an organization can create barriers to teamwork. In a traditional bureaucratic structure, top management and departmental specialization predominate. Redesign of the organization must remove the layers and open up communication. If teams are going to make decision that support organizational goals, they first need free access to information and to provide input on overall operation.

Working in a team and manage a team can become the basic characteristics of the work carried out in Romanian organizations. Availability of teamwork is a requirement of the current recruitment announcements, and the presence of necessary qualities, or on the contrary, their absence may be decisive factors in hiring a person, or to keep them in the organization. The need for teamwork has become increasingly evident as the human resource policies have evolved and Romanian companies began to consider the need for communication and human contact of their employees, realizing high motivational value of dialogue and mutual support in a team

Research of theoretical, methodological and practical advantages of teamwork in organizations has enabled us to synthesize the following results of investigations:

➤ To Romania, developments taking place internationally is a chance that the integration process of transition from industrial society to knowledge society without attending preparatory stages. The main resources of knowledge society and material resources are not money but knowledge is illustrated mainly by human and social capital. Power is not given by money, providing control and distribution of resources, but given the knowledge to ensure equitable distribution of resources and labor factor mobility. Teams bring together complementary skills and experiences that, by definition, exceed those of a single person on the team. This broad mix of skills and experience enable teams to respond to complex challenges such as innovation, quality and customer service.

➤ Currently, the working environment of the Romanian organizations tend to encourage inefficient individualism, where people are concerned to achieve their own goals, goals that do not necessarily coincide with those of the company where they work. In these circumstances, if a company wants to operate effectively in a climate conditions based on teamwork and serve the common interest, the most difficult obstacle to overcome is to create an organizational culture based on teamwork.

➤ In the Romanian organizations, teamwork must be accepted and included in the approaches of leadership performance. The management team is to create conditions to ensure its success: establishing a compelling purpose, forming a group to work efficiently, ensuring that organizational support helps the team to do their duty and careful planning of the intervention leaders. The main concern of a team leader is to create a culture that promote and maintain qualitative and quantitative performance of his team, stimulate and innovate, to change, to seek solutions to new challenges. A leader's role is to ensure that the individual contribution to the overall goal of the team is formally assessed, so that team members receive clear feedback on their work. It is very important that team members feel involved as much as possible in all aspects of

their work and planning decisions. This involvement leads to increased accountability and dedication to the company, lower staff turnover and retention in the company's best employees

➤ Employees tend to benefit as much as organizations in a team environment. Teams can provide a sense of self, human dignity, identification with work and sense of self - confidence and self - fulfillment, for which current workers seem to work. The teams give employees the freedom to grow and gain self respect and dignity - management making decisions about their work. As a result, employees work better and face less stress at work. Team members feel they have an interest in the results, the achievement of tasks, the team are dedicated and do not want to disappoint.

➤ Modern organizations will have to find a way to recombine spontaneously to form multidisciplinary teams and high performance, working in a natural way. The skills of teamwork are essential for teams to operate successfully. This means that the organization will be to prepare people for them to acquire all necessary skills. Where appropriate, individuals will find the position of leaders of a team, members of another and subordinates in the third team, roles are defined by the nature of work. Operating within these different roles require a completely new range of skills in relation to those required in a traditional organization

Teams can be real work force in increasing productivity and promoting change if:[4] formal group structure is the same with the informal group; there is a competition between the teams, which can lead to increased performance; management staff has knowledge of human resources and also have the skills and motivation for their application in practice

3. Conclusions

Teams are not the solution to everyone's current and future organizational needs. They will nor solve every problem, enhance every group's results, nor help top management address every performance challenge. Moreover, when misapplied, they can be both wasteful and disruptive. They represent one of the best ways to support the broad-based changes necessary for the high -

performing organization. And executives who really believe that behaviorally based characteristics like quality, innovation, cost effectiveness,, and customer service will help build sustainable competitive advantage will give up top priority to the development of team performance.

Teams are a critical method for facing the challenges of globalization, increased competition, and ever-evolving technology. Companies form teams for different reasons, but most teams are created to solve problems and ensure that an organization becomes more flexible, effective, and competitive. However, simply putting a team in place is no guarantee it will produce results. All teams need support and training in order to help them work effectively and productively.

Teams are important for organizations because:

➤ Organizations must keep in the forefront that the customer is truly number one and that customer satisfaction is a critical and worthwhile goal. Companies must creatively find new and appropriate ways in which all work team know, understand and are responsive to the need of their customer.

➤ Organizations must be committed and focused in giving quality products. Organizations must be willing to create an environment that supports teamwork in which work teams can find new and creative ways to meet the customer needs for quality products and services.

➤ Organizations must develop leaders that have the appropriate philosophy, attitude, commitment and skills that can set a good example of teamwork.

Benefits of the Informal Organization

Stan Ștefania Anca
„Vasile Alecsandri” University of Bacau
anca_stan68@yahoo.com

Abstract

In today's world, with development of economic globalization and competition among enterprises of the content, in addition to markets, products, technologies, increased competition in human resources. The purpose of study of the informal organization is to its as a human resources can be developed, the correct guidance, the positive role played by the informal organization to avoid the damaging effects, so that the work of groups rationalize and improve efficiency. Ignoring the informal organization can be a major mistake in light if today complex and dynamic organizational structure. Managers need to learn to work with both formal and informal structure. Business can best be managed through a balanced implementation of formal and informal organization.

Key words: formal organization, informal organization, informal leader, organization

J.E.L. classification: M19

1. Introduction

In all businesses there are two organizations: one that is shown on the formal organization chart and another that exists in reality. The formal and informal systems mirror each other and go together.

2. Formal and informal organizations compared

An organization is neither totally formal nor totally informal. It is a combination of formal and informal aspects. Approaching the informal without appealing to the formal would be incomplete. The line separating formal and informal organization is not always clear. Formal organization is created by management to achieve organizational

objectives. Informal organization originates from within the formal organization to meet the social and cultural needs of people. For an effective manager to be successful in managing his staff, it is essential to understand the formal and informal organization.

A formal organization is characterized by several distinct features: [1]

- ✓ a common goal; an accepted pattern of purpose
- ✓ a set of shared values or common beliefs that give individuals a sense of identification and belonging
- ✓ continuity of goal – oriented interaction
- ✓ a division of labor deliberately planned to achieve the goal
- ✓ a system of authority or a chain of command to achieve conscious integration of the group and conscious coordination of efforts to reach the goal.

An informal organization refers to all the channels of interaction that are not defined by the formal organizational. The informal organization challenges a manager because it consists of actual relationships that have real consequences on worker's behavior but that are not prescribed by formal organization, and, therefore, not shown on the company's organization chart. The informal organization is a system of interpersonal relations formed spontaneously within all formal organizations. It consists of a dynamic set of personal relationships, social networks communities of common interest, and emotional sources of motivation.

An informal organization is one that exists naturally within a social structure. As individuals find common interests or purpose, they have tend to operate more closely with one another than with others they have little in common with. These relationship can be and frequently are more influential than actual formal organizations. They don't have any documented

accountability requirements or procedures that drive their performance and behavior. They function through discretion and personal choice.

The main points of difference between formal and informal organizations are given below:

Formation:

- ✓ formal organization – deliberately planned and created by management
- ✓ informal organization – emerges spontaneously as a result of social interactions among people.

Purpose:

- ✓ formal organization – to achieve planned goals of the organization
- ✓ informal organization – to satisfy social and cultural needs of members and fulfill common interests.

Structure:

- ✓ formal organization – has a well – defined structure of tasks and relationships
- ✓ informal organization – a complex network of relations.

Leadership:

- ✓ formal organization – managers act as leaders by virtue of their superior position
- ✓ informal organization - members voluntarily choose their leaders.

Communication:

- ✓ formal organization – formally established or official lines of communication
- ✓ informal organization – members communicate informally according to convenience.

Organization chart:

- ✓ formal organization – official structure, can be shown in the form of a chart
- ✓ informal organization – unofficial structure, not shown on the chart of the company.

Rules and regulations:

- ✓ formal organization – written and fixed, violation leads to penalties
- ✓ informal organization - oral norms, violation leads to social disapproval.

The informal organization provides leadership to members in addition to what the formal structure provides. Any formal organization functions best when the informal organization support it. Formal and

informal goals may be complementary if the members of the informal organization perceive benefits from working in a unified way with the formal structure. Sometimes the informal structure may conflict with the formal one. Where this is the case the organization may become less efficient at meeting its stated objectives.

In every organization, there is a continuous interplay between its formal networks and its formal structure. Formal policies and procedures are always filtered and modified by the informal networks, which allow workers to use their creativity when faced with unexpected and novel situations.

The relationship between the formal and informal organizations is always subtle always complicated and always interesting.

3. Impact of the informal organization

The informal organization can affect the formal organization positively and negatively. The informal organization is important to the personal integrity, respect and independence of individuals in the formal organizations.

The informal organization has the potential to be helpful to managers in the following ways: [2]

Makes the total system effective. A formal organizational policies, systems, plans can not solve all the problems that exist in the organization, it can not meet the needs of all members, the organization of the situation is constantly changing, with dynamic nature. The informal organization is relatively flexible, organized some of the issues in the informal organization can be resolved in the interpersonal relationships with members of some of the requirements can be met in the informal organization.

Provides support to management. The informal organization can provide support to the individual manager. If the manager will accept assistance, the informal organization can fill in gaps in the manager's knowledge through advice or through actually doing the needed work. When the group performs effectively and positively, it builds a cooperative environment. This, in turn, can lead the manager to delegate more tasks to the employees.

Provides a useful communication channel. As the informal organization is the spontaneous formation of people's interactions, and interpersonal communication have become a way to maintain the informal organization. People in the informal organization to pass a variety of information, understanding what is happening around, talk to their own feelings.

Provides stability in the workplace. Informal organizations tend to make employees more than the formal organization creates a sense of belonging and a sense of security, because people in the formal organization not only to share work – related content, but also the lives of more or emotional exchange. Therefore, the informal organization that provides its members in formal organizations, it is difficult to get the satisfaction of psychological needs to create a more harmonious, harmonious interpersonal relationships, improve the spirit of mutual cooperation of members.

Encourages better management. Managers should be aware of the power of the informal organization in what is actually a checks- and – balance system. Planned changes should be made with an awareness of the ability of the informal group to make the plan successful or unsuccessful.

Although the informal organization will bring some benefits, but also the organization will usually bring some potential problems.

Develops pressure for conformity. The norms of informal groups strongly pressure group members to conform. The more cohesive the group, the more accepted are the behavioral standards.

Creates conflict. Because an employee not only the formal leadership of the organization to meet the requirements, but also meet the requirements of the informal organization, the requirements of the two may sometimes be contradictory, in which case the employee organization would be confused.

Resists change. The informal organization can resist change. In an effort to protect its values and beliefs, the informal group can place roadblocks in the path of any work modifications.

Unable to effectively control. As the power of the informal organization is independent of the formal organization of the power system, so the power of the formal organization of the informal organizations is

sometimes unable to effectively control. Especially when there close of the informal organization, its interests and objectives of management effectiveness will reduce or even obstacles, and thus unable to complete the work of the organization goals.

Tended effectively, the informal organization complements the more explicit structures, plans, and processes of the formal organization: it can accelerate and enhance responses to unanticipated events, foster innovation, enable people to solve problems that require collaboration across boundaries, and create footpaths showing where the formal organization may someday need to pave a way

To return to a long – term performance, companies will need to embrace both formal and informal structures that are present in every organization.

4. Working with the informal organization

One concept to keep in mind concerning the informal organization is that it serves many useful purposes for its members, it usually provides a satisfactory amount of social affiliation and interaction as well as information to workers rapidly. The informal organization is capable of controlling or influencing the behavior of its members if their actions become so far out of line with formal organization expectations that they tend to create problems and dangers for the informal group. [3] In many cases, the informal group even works to support and achieve formal goals and objectives that are in harmony with informal ones. Since the informal group is capable of performing for its members many positive, constructive tasks that are desirable from the formal point of view, the group should be permitted and encouraged to perform these supportive functions. In meeting personal and group needs and in regulating worker behavior constructively, the informal organization can be a very helpful auxiliary to formal manager.

Managers need to learn to work with both formal and informal structure. A flexible manager will realize that elements of the informal structure can be formalized i.e. by adapting the formal structure to incorporate

improvements which result from the day – to – day working of the informal structure. Because the informal organization is inevitable, the manager must develop methods for influencing it.[4]

One of the most direct ways for a manager to influence the informal organization is by tapping its grapevine, learning what is being communicated, and countering any negative rumors by getting the formal organization's message into the channel. This can be done by learning who the liaison people in the informal network are and using them as a point of entry. The manager must also work closely with these people and show them that the company is interested in them and views them as important resources.

Another way for a manager to influence the informal organization is to understanding the roles of informal leaders and learning how to leverage them. Informal leaders play key roles: they are motivators and enablers, inspiring teams and management to accomplish goals; as agents of execution, they drive the business forward and get results; they are advocates for the business, mentoring and supporting others to achieve their objectives; as communicators and connectors they bridge the communications gap between management and employees; they serve as an extension of the manager when the manager is absent. An excellent way of putting the informal organization to work for the good of the company is to bring informal leaders into the decision – making process.

5. Conclusions

The informal organization exist everywhere. Ignoring the informal organization can be a major mistake in light if today's complex and dynamic organizational structure. Knowing its features means being able to handle and guide the firm in the right direction. Armed with theoretical and practical knowledge, managers will be able to take a step toward dominating the liberal or conservative tendencies of the organization. They will be able to stimulate or subjugate these according to the requirements and aspirations of the firm.

By mobilizing the power of the informal organization, Romanian companies will benefit from faster decision – making and improve execution, as well as from having more highly motivated employees whose behaviors are better aligned with organizational goals and strategies.

Managers of Romanian companies should realize that informal organization cannot be done away with. They should try to integrate both formal and informal organizations such that facilitates the achievement or organizational goal. There are certain guidelines to be followed in managing informal organizations:

- ✓ The management should realize that informal organizations can co – exist with the organization and should take the help of informal organizations to achieve organizational goals.

- ✓ Identifying the leaders of informal organizations who are most influential and maintaining good rapport with them will help managers to work efficiently.

- ✓ The management of the organization should try to integrate the interests of the informal organizations with those of the organization.

- ✓ The management should try to find out the reason for the formation of the informal organizations and how far the management is responsible for actions of informal organizations.

- ✓ The management can encourage the existence of informal organizations by molding them in line with the interests of the organization.

Firms are unique as living entities and as such may respond to similar economic phenomena with opposite result. Managers should then be aware of the impact of the informal in the organization over which they rule and learn how to cope with it. They should realize that every human contact has an echo. And some contacts may even change an individual's nature. The efficient management of informal organizations can help in better organizational functioning.

Considerations about Retailing Trends

Stanciu Anca

Condrea Elena

„Ovidius” University of Constanta, Faculty of Economic Sciences

castan22us@yahoo.com

Abstract

Retailing has experienced a number of changes over the past decades and many trends are expected to continue in the future. Retailers should understand these trends as a method of planning and developing successful strategies. Retailing innovations should be carefully examined and considered for possible use in the market. Changes in the population, store trends and the retail promotional mix are all factors that must be studied in order to predict the future retail environment.

Key words: retail, ethic, competition, trends.

J.E.L. classification: M21, M31

1. Introduction

The present paper aims to discuss some of the major retail trends that retailers faced and are likely to face over the next year.

Market trends-there are several trends relating to the market that will affect a retailer's operation: population changes, household formations, ageing of people, income distribution, ethnic population growth or consumer sophistication.

2. Content

There are some features and trends that must be underlined to better understand the retail global configuration.

Concerning the demographic changes there can be mentioned:

- The increase in population changes-the increase in population comes an expanding need for retail services, could be the result of both an increased birthrate and immigration; all population changes will affect the buying habits and preferences of the market.

- Household formations-although the population will increase steadily during the 1990's, the expected rate of growth will slow somewhat. This will be paralleled by a corresponding decrease in the formation of households. As the household tends to be the base for retail spending this will have a significant impact upon retailers. To compensate, the spending power and influence of working women will continue to increase. Retailers will continue to find the female market for goods and services an attractive one as more women enter the workforce.

- Elderly population-one important demographic factor will be the age distribution of the population. Better health care and a healthier, more fitness-oriented lifestyle should permit increased percentage of population to live beyond the age of seventy. As a result of this trend, a new retail market will expand to areas where this age group is the major purchaser of health and personal care products, travel packages, fitness products, educational programs and restaurants dining. If the retailers begin to realize the impact age has on business, there will be a headlong rush to grab a share of the thirties plus market. Ultimately the market will become glutted and those retailers that learn best what this customer wants will succeed most. And, at the same time-while merchandising to the junior customer is increasingly abandoned – some astute junior-apparel retailers may once again win that market share.

- Income distribution-for approximately the past fifty years, the large middle-income portion of the population was the prime target for retailers because it tended to make up the largest group. Today, it is no longer case. Increasingly, despite of economic crisis, income trends show the market is polarizing into two groups-the low income and the high

income wage earners. This polarization has caused an interesting shift in retailing objectives as both new high- end and low-end stores have been experiencing success. For instance, many new stores carrying designer labels and high- priced merchandise have emerged in an attempt to meet the increased affluence of the high-income market. Famous international designers, such as Gucci and Ralph Lauren have opened stores in major cities of the world, in order to capture the market. On the other side, the growth of discount retailers has been due largely to the unprecedented growth in the low-end income market.

- Ethnic population- over the last 150 years, countries like Canada, for example, has become home of people from many different other countries. Within the last few decades, there has been considerable immigration all over the world, from countries such Italy, Portugal, Poland, Romania, Bulgaria, Moldavia, the former Soviet Union and far eastern countries including China, Vietnam, India, Philippines and more. The ethnic population growth brought about by each new wave of immigration provides unique retail opportunities for the emergent markets. Some of these new immigrants open retail stores that often sell specific food stuffs or clothing to other members of their ethnic group. The result of this has been a colourful mosaic of good and services in many big cities of the world. Some future immigration trends can be anticipated. This will lead to numerous retailing opportunities for housing, food, clothing and various other products for the emergent markets. Some stores that are located in the predominantly ethnic areas make it a policy to hire staff members who are fluent in the appropriate foreign language in order to service their customers better. Wise retailers of the future will keep abreast of changes in the ethnic mix of their store location and find new services and products to satisfy the needs of the community. The globalization of markets means that retailers will have many opportunities to expand elsewhere. In the past, some retail organizations have done so with mixed results. However, the relaxation of trade regulations and changes in the Eastern Europe signals opportunities that many retailers took advantages of. A good example

of such success is the McDonald's establishment in the eastern European countries, even in the former Soviet Union. Whether the retailer is located in the USA, Europe or elsewhere, however, care should be taken to understand the effects on demand as a result of the ethnic factors.

- Consumer sophistication-with a population that is becoming more educated, the sophistication of the average consumer has also increased. This has led to changes in product demand. For example, a low price is no longer sufficient to guarantee high retail sales because today's consumer demands quality as well. The retailer who can offer a quality product at a low or reasonable price has the best chance for success. Another important aspect of consumer sophistication concerns the exposure that consumers have to various specialized and ethnic products and their willingness to sample these items. One good example of this is food. Urban consumers have been exposed to foods from many different parts of the world including the West Indies, Europe, the Middle East and Asia. A wide variety of ethnic restaurants, which cater to more exotic food tastes, can be found in urban centres. In addition, many mainstream grocery and food chains have added ethnic foods to their regular stock. It is not unusual to find exotic fruits such as kiwi and mangoes in traditional food stores. Affluent and sophisticated consumers frequently demand high quality and high priced products that are well designed and manufactured. The success of European companies such as Moulinex and Braun in the areas of food processing equipment and personal care products testimony of this fact.

Today's increasingly demanding consumers has fostered the growth of consumerism.

Defined as the organized expression of dissatisfaction with business practices consumerism requires that retailers listen and respond to consumer concerns.

As the demands on consumers' time increase, the convenience aspect of retailing should also increase in importance. Some industry experts predict that time and convenience will be important criteria to gain a competitive edge in the future. Retailers who offer goods and services at the convenience of the consumer will be successful in this years. By capitalizing on

this poverty of time, services retailing has become the fastest growing part of the industry. Services retailing represents another area of opportunity for the retailer. Similarly, franchising is once again experiencing an upsurge in growth.

Another important trend in consumer demand is the increased concern on the part of the public for the environment. For the retailers this means a consideration of products, packaging and store operations and the affect they have on the environment. Some retailers have incorporated this concern into their operations by adding environmentally friendly products.

Retail Store Trends

Changes in the population usually bring about changes in the style, size, location, and operation of the retail store. Retailing has involved from the wooden floors and crowded displays of general stores of the past to the sleek lines and sophisticated displays of the boutiques of today. However, the changes that have occurred in the past will be minor compared to the retail changes that are likely to occur within the next two to three decades.

Store design

One of the major changes that has occurred in retailing concerns store design. Store sizes have changed from small to large and back to small again. Currently, stores are either large establishments such as super center consisting of 100000 square feet of display space, or small boutiques containing only 400 to 1000 square feet of display.

The nature of of retail operations has also changed. Many stores today follow either a self-service or a full service mode. Large retailers have moved towards the self-service end. In this type of operation, customers come into the store, find what they need and pay it at a checkout counter. There are a minimum of retail sale people. The primary responsibility of most clerks is to keep the shelves stocked and to answer any consumer inquiries. This type of operation is beneficial to both the consumer and retailer. Consumers are able to walk into a store and live again in a short space of time. For the retailer, this

type of operation reduces labour costs so that prices can be lower and displays can be improved.

This approach has worked extremely well with food stores and department stores. However, in specialized area such as delicatessens in food stores, or large appliance sections in department stores, higher service levels are still maintained and a greater number of clerks is required to assist the customer.

The small full-service boutique is quite the opposite of the self –service store. Here the retailer has a sufficient number of clerks on staff whose primary responsibility is to assist customer. This is especially common in fashion stores which cater primarily to the high-end market. For consumers, this type of of store has a number of advantages. First, they are assisted by a salesperson from the moment they enter the store. This create a comfortable and intimate shopping atmosphere where the sales clerks get to know their regular customers` needs so they are able to serve them better. The disadvantages is that the prices tend to be higher in these stores than in self- service stores. Yet, it seems that higher prices do not discourage customers, as many feel the additional service is well worth the extra cost. This type of retailing, referred to as "niching", is expected to continue

Throughout the decade as markets become more fragmented and consumers demand more specialized service.

For the retailer, a full service establishment is more expensive to operate in terms of staffing and rental costs but compensation is provided by the considerably higher average sale per customer.

Store location

Store location have changed over the years as well. Originally, stores were located in the main business district of a city or town. Each store was usually operated by the owner. During the 1950s and 1960s stores tended to move away from central business to districts to outlying suburban shopping malls. These malls provided attractive clusters of stores for a growing suburban clientele. In addition, with the increased dependence on the automobile, suburban mall locations provided ample free parking

for the customer. As a result, many downtown business districts fell into decline and retailers in these areas struggled to remain in business. Many central business districts in cities are being revived and trendy new stores are moving in. Similarly, suburban malls have found their customer traffic is decreasing and some malls have even closed. It is likely that, in the future, new malls will become more specialized. A large concentration of stores is an attractive magnet for the consumer, and, by adding entertainment features, a whole new shopping experience is created. Some independent retailers have noticed the value of entertainment for shoppers and have added in-store restaurants and playrooms for children. One notable example of this is the IKEA chain from Sweden which is a worldwide retail presence and a strong believer in combining shopping and entertainment.

Other retailers prefer to locate in small strips or in specialized business districts. Sometimes, a number of small retailers provide specialized goods and services and are located in a cluster. The combined effect of all these retail stores helps draw consumers. The addition of open-air restaurants and sidewalk cafes often enhances the area by providing not only a place to shop and to eat, but also a place to socialize.

Retail competition

The retail industry has, in the last decade, experienced a trend toward increased consolidation and concentration by the major chains in the form of mergers and acquisitions. For smaller retailers in high developed countries this will likely mean stronger retail competition as the larger chains are better able to take advantage of economy of scale. Increased competition is also expected to come from foreign firms.

In the past, retail competition has consisted of one store competing against another. In the future, the growing trend of nonstore retailing outlets will prove to be a significant threat to the traditional retailer. Examples of nonstore retailing include mail order retailing, door-to-door sales, sidewalk and street vendors, and electronic retailing. The retailer of the future will have to

compete against both non-store and regular store retailers. This will be especially prevalent in areas such as gift wares, specialty foods and fast foods. Some retailers are already meeting the challenge of non-store retailing by going into the non-store retailing area themselves, while keeping their regular retail outlets. Successful, small specialty retailers maintain both a retail store and an active mail-order clientele. Both of these activities are major contributors to the success and overall profitability of the operation. Other retailers may work in the opposite direction, starting out as nonstore retailers and eventually building up sufficient clientele and profits to open a full-scale retail establishment.

Automation

In the past, many of the advances in retailing as a result of automation were concentrated in the warehousing – distribution area. However, automation is playing an increasing role in the retail store itself. From yesterday's large mechanical cash register to today's modern electronic point-of-sale device, there have been tremendous changes in the retail world due to computerization and automation. The introduction and development of the universal product code (UPC) has allowed retailers a greater degree of control over their inventory and has lessened the number of errors that occur when entering data at the point-of-sale terminal. A special lightwand scans the UPC code and immediately enters the sale data into the store's computer. This computer then registers the price, calculates any applicable sales tax, and prints out the customer's bill of sale. The store's inventory records are continually adjusted and the store owner/manager is able to determine inventory as well as sales levels on a daily basis. Not only are scanning devices efficient and helpful to the consumer but they also allow the retailer to gain valuable information about the customer transactions.

Credit cards become a major fixture in retailing, and today, instead of entering all the data from the credit card by hand, a machine automatically reads the magnetic strip on the back of the credit card, obtains authorization, and automatically prints up the customer's charge slip. This machine has

helped prevent credit card fraud. Electronic funds transfer allows the retailer to have money transferred from the customer's bank account directly into the retailer's account as the sale occurs. This essentially becomes a cash sale and can represent a major cash saving for the retailer.

Retail research has also been greatly enhanced through retailers' use of consumer databases and computer assisted surveys. Automation is also contributing to creative devices for in-store promotion.

Promotion

The promotion of the retail store has changed considerably within the last decade and is likely to change even more during the period of 1990s-2000s. In general, the dominant form of retail promotion has been the printed media where newspaper advertisements or door-to-door flyers have been common. Also, some retailers, spend a great deal of time and effort producing catalogues for their customers and the production costs, which include photography, copywriting and printing, are very high.

Many retailers are moving away from the printed media in favour of the electronic media. For example, the use of radio commercials is an increasing phenomenon in retailing. Many of these commercials are scheduled for the rush hour slots when people are in their cars going to or from work.

Local television has also become a viable advertising tool and, while some retailers now use it to supplement their print or radio advertising, it is quite likely that in the future some retailers will use it as an exclusive means of promotion. While television advertising is extremely expensive, it can give a new retail store rapid exposure to a large segment of the consumer population. Some large urban centres have ethnic television stations that broadcast messages in various languages. Frequently, the advertisers here are retailers who sell specialty products to a largely ethnic clientele. The cost of advertising on these stations tends to be substantially less than on larger network stations, which makes advertising on television an affordable proposition for certain retailers.

Retailing Ethics

Many ethical issues facing retailers have been discussed already. Examples include the areas of retail research, legislation, layout planning, human relations, management, pricing, personal selling, customer service and promotion. Retail managers may be called on to make decisions involving ethical issues in each of these areas. As ethical considerations are seldom clear-cut, the retailer would be wise to develop broad guidelines or policies to provide guidance when such questions arise.

In many cases the ethical decisions may not lead to successful short-run sales performance but often contributes to a positive image and reputation leading to long-term success. The retail manager may look beyond what is „legal” because what is perceived as „unethical behaviour” often leads to legislation.

In the last years, retail managers will be faced with even more complex decisions that bear ethical overtones. Increased competition, technological advances, and socioeconomic changes all suggest that new situations will emerge requiring increased sensitivity to ethical questions.

3. Conclusions

The future of retailing will be affected by the changes in population, ageing, ethnic population growth, income, household formation and consumer sophistication. In the past few decades, there have been changes in the style, size, location, and operation of the retail store. Automation has helped the retailer control inventory levels with a greater degree of accuracy and has provided a more efficient internal management information system. Although print media and radio advertising are important for retailers there will be a greater reliance on television advertising in the future.

Accounting Policies Regarding Environmental Costs

Stanciu Ionela Cornelia
„Valahia” University of Târgoviște
stanciu_ionela09@yahoo.com

Rof Letiția Maria
„1 Decembrie 1918” University of Alba Iulia
letitiamariarof@yahoo.com

Abstract

The purpose of this article is to present certain aspects regarding the involvement of accounting in the environmental issues that a company may face, to also present environmental costs and the chance to reflect them through environmental accounting. The main objectives taken into account by the article were to define the concepts of environmental costs, and to describe how environmental management accounting may be useful in determining environmental costs. The scientific demarche is based on information from the national, European and international specialized literature and practice. Our approach turned to research methods like documentation, analysis, synthesis, comparison, all these being part of the positivist research current.

Key words: accounting, environment, environmental accounting, environmental costs, environmental management accounting
J.E.L. classification: M41, O13

1. Introduction

Considering the intense normalization and standardization process in accounting, it must be known that in terms of environmental management and protection there are sustained efforts for a joint representation of such activities. The emergence of environmental accounting goes back to the 1970s; since then, the interest for this area has grown considerably and managers have started to pay more attention to environmental issues. Accounting is required to submit various types of user information on the financial position and performance of

entities in the management of resources at their disposal. Historically speaking, the accounting was limited, mostly, to the resources represented by material and financial goods of entities. This became less appropriate, being left out of accounts significant "costs", such as environmental, social, which were not found in the financial statements of entities. This is because entities didn't "pay" anything for the environment, and only little for social issues. This does not mean that society as a whole does not support these "costs". Various other factors have forced the conservative to take measures of modernization. In recent decades a growing number of entities give great importance to environmental issues and their reflection by accounting, either under the influence of administrative regulations or because of their information needs. In certain circumstances, for certain fields, they can have a significant impact on the financial statements, and that of their users.

2. The need to involve accounting in the environmental problems of the entity

Environmental issues are starting to become an area of interest for the users of financial statements; a growing number of entities are beginning to pay attention to these issues also.

Today, the concept of natural environment or environment is associated with three perspectives [1]. According to the *first perspective*, the environment is *the set of natural resources*. It is the initial notion of the environment and the most intuitive. It emerged as a result of several analyses and findings at the end of the 20th century, which gained growing significance as the chance to

observe global economy as a whole increased. According to the *second perspective*, the environment represents *the interaction between natural resources and human activities*. This is the notion with the most uncertain limits, which occur from the negotiation between different abilities and disciplines. In terms of the *third perspective*, the environment is the *set of all available resources*. This is the notion that derives from the concept of sustainable development, according to which environmental, social and economic elements are actually indissoluble.

Bennet and James (1997) identified six fields related to the association between environment and accounting. The goal of this association is to ensure that the management of the entity has sufficient information to improve the management of the decision-making process. Bennet and James (1997) claim that the environment-environmental accounting association may be effective in improving the efficiency of the entity's management by: identifying and reducing costs, prioritising environmental actions, directing the process of establishing prices for products, increasing the client's value, making investment decisions with consequences on long term and assessing the eco-efficiency and/or sustainability of the entity's activities [2].

The incorporation of environmental issues in the life of the entity involves taking them into consideration in terms of economy, legal framework, accounting, finance and technique (Lafontaine, J.P., 2002). In terms of *economy*, taking into account environmental parameters in the cost of services and products allows the entity to ration the consumption of natural resources or energy on one hand, achieving substantial savings, and, on the other hand, it allows to meet the requirements regarding the environment and the consumers' health. In terms of the *legal framework*, taking into consideration the environment is imposed by the risks that engage the responsibility of the entity. This responsibility is generated by non-compliance with the environmental legislation and may result in administrative and/or criminal sanctions. In terms of *accounting and finance*, recording environmental costs generated by the activity of the entity and presenting the associated

financial information represent a mean of assessing performances [3].

Involvement of Romania's accounting in the business of environmental protection is even stronger with the entry into force on January 1, 2010 of the Order 3055/2009 for approving the Accounting Regulations in accordance with European directives, so in the chart of accounts, a new account is inserted, account 652 "Expenditure on environmental protection. With this account is recorded environmental protection expenditure recorded in the relevant period, for example, environmental taxes paid, the certificates of emissions of greenhouse gases effect purchased.

3. Environmental costs – premise of environmental accounting

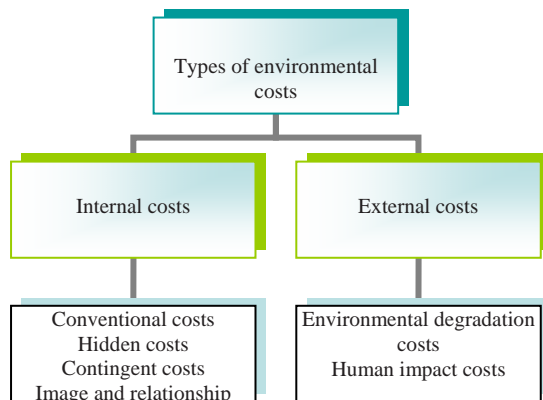

The main component of environmental accounting is the environmental cost. Over time there have been many definitions for the concept of environmental cost, and we will analyze these definitions next.

European Commission Recommendation 453/2001 makes the distinction between environmental costs and other costs, defining them as costs of the actions undertaken by the economic entity and by third parties in the name of an economic entity with the purpose of preventing; reducing or repairing the environmental damages resulted from operational activities. These costs include: waste storage and disposal, soil protection, underground and surface water protection, clean air and climate protection, noise reduction, biodiversity and landscape protection. The definition given to environmental costs by the United Nations Conference on Trade and Development (UNCTAD) posits that they "comprise the costs of steps taken, or required to be taken, to manage the environmental impacts of an enterprise's activity in an environmentally responsible manner, as well as other costs driven by the environmental objectives and requirements of the enterprise".

The Environmental Protection Agency defined environmental costs as being costs with a direct financial impact over entities (internal costs) and individual costs, for which the entity is not responsible (external costs). This definition is the basis of the

distinction between environmental costs, which is seen below [4]:

Figure no 1. Types of environmental costs

Source: Patrick de Beer, Francois Friend, Environmental accounting: A management tool for enhancing corporate environmental and economic performance, Ecological Economics Journal, no.58, 2006, p. 550.

According to the Environmental Protection Agency (1995), *internal costs* include:

- *Conventional costs*, which include costs with equipments, raw materials and consumables;
- *Hidden costs*, which refer to the results of assigning environmental costs to indirect costs or overlooking future and contingent costs;
- *Contingent costs* refer to environmental costs that will not occur with certainty in the future, depending on uncertain future events, such as the costs involved in a future restoration process;
- *PR costs* are less tangible because they cover the subjective perceptions of management, clients, employees, community and regulators. This category may include costs of the annual environmental reports, as well as costs for environmental activities, such as planting trees.

External costs include the costs of environmental degradation for which the entities are not legally responsible and which have negative consequences on humans, property and their well being, and can't be always compensated through legal systems. Determining the financial value of external costs is difficult, but, nevertheless, some entities are trying to approach these costs as

part of their environmental accounting system.

IFAC makes a distinction between waste and emission control costs, prevention costs and other administrative costs, such as the research and development activity, which helps to increase eco-efficiency.

According to the IFAC (2005) classification, the following costs are considered environmental costs [5]:

a. Materials Costs of Product Outputs: Includes the *purchase costs* of natural resources such as water and other materials that are converted into products, by-products and packaging.

b. Materials Costs of Non-Product Outputs: Includes the *purchase (and sometimes processing) costs* of energy, water and other materials that become Non-Product Output (Waste and Emissions).

c. Waste and Emission Control Costs: Includes costs for: *handling, treatment and disposal* of Waste and Emissions; *remediation and compensation* costs related to environmental damage; and any control-related *regulatory compliance* costs.

d. Prevention and Other Environmental Management Costs: Includes the costs of *preventive environmental management activities* such as cleaner production projects. Also includes costs for *other environmental management activities* such as environmental planning and systems, environmental measurement, environmental communication and any other relevant activities.

e. Research and Development Costs: Includes the costs for *Research and Development* projects related to environmental issues.

f. Less Tangible Costs: Includes *both internal and external* costs related to less tangible issues. Examples include *liability, future regulations, productivity, company image, stakeholder relations and externalities*.

From our point of view, environmental costs are those expenses incurred to prevent, reduce or repair damages caused to the environment, incurred at the initiative of the entity or required by the regulations and rules in place to reduce the environmental impact of the entity and to reduce the environmental risk.

4. Environmental management accounting – the main tool used by the entities to determine environmental costs

Environmental issues, together with associated costs, revenues and benefits, are a growing concern for the citizens and corporation leaders in most countries of the world. As they are now, the accounting practices don't provide sufficient information to support the decision-making process regarding the management of the environmental responsibilities. In order to fill this gap, at the beginning of the 1990s, the US Environmental Protection Agency was the first agency to set up a program that promotes the adoption of the environmental management accounting (Environmental Management Accounting – EMA). Since then, organizations in 30 countries have begun to promote and implement environmental management accounting for various types of management initiatives related to the environment. The International Federation of Accountants (IFAC) decided to authorize the creation of a guidance document regarding environmental management accounting, a document that was based on the first two publications of the ONU DSD EMA Group, in order to put together the best information about environmental management accounting and, at the same time, to update and complete it. This is intended to be a guidance document that provides guiding information, being "a middle way" between regulatory requirements, standards and pure information. Therefore, its purpose is to reduce international confusion on this issue by supplying a general framework and a set of definitions for EMA, which is quite comprehensive and consistent with other existing ones, used widely for environmental accounting. A recent evolution of EMA is to include social aspects also and to move emphasis from "environment" to "sustainability". According to the IFAC analysis, the environmental management accounting practice moved beyond the provision of information by focusing on reducing waste (for example, reducing loss of resources) and generating value (for example, the efficient use of resources).

As in all cases, environmental management accounting is a tool to inform managers about environmental costs and the quantification of the effects of the entity's activity over the environment. It emerged as a result of the growing pressure over the entity's management to reduce costs, but also to minimize the environmental impact of the activities [6]. This pressure comes from internal users, but especially from external ones (public authorities, consumers, investors, mass-media).

Environmental management accounting (EMA) is defined as the generation, analysis and use of financial and non-financial information in order to support management within the framework of society or business [7]. EMA incorporates environmental issues and business policies and, thus, provides guidance for the building of a sustainable business. EMA examines financial costs and environmental benefits, contributing to the recognition of high and rising levels of capital and operating expenses for pollution control equipments and environmental taxes.

An essential feature of environmental accounting is that its implementation requires several disciplines [8]: first, environmental policy should be integrated within the global and strategic policy of the entity; second, there are the disciplines involved in producing environmental and reporting costs; third, there is the auditing requirement that ensures conformity with environmental regulations and adequate reporting of environmental accounting.

Because environmental management accounting provides financial information, as well as non-financial information, there is an opportunity to split environmental management accounting into Monetary Environmental Management Accounting – MEMA and Physical Environmental Management Accounting – PEMA. **Monetary Environmental Management Accounting** (MEMA) is used for internal management decisions and aims to identify and treat costs and benefits that emerge as a result of the environmental impact of the entity (Schaltegger and Burritt, 2000). Regarding its methods, MEMA is based on the adapted traditional management accounting that will be applied to the environmental aspects of the company's activities. It is focused on assessing the

environmental impact in monetary terms (costs with fines received for violating environmental regulations, investments in pollution prevention projects). MEMA is the central and ubiquitous tool that underlies most internal management decisions and approaches the issue of identifying, monitoring and treating costs of the environmental impact of the entity. MEMA is a system that emphasizes the economic impact of the entity's activities influenced by environmental aspects and contributes to the strategic and operational planning and provides the main basis for decisions directed towards achieving the desired objectives and acts as a control instrument.

Physical Environmental Management Accounting (PEMA) serves as an informational tool for the internal management decisions, using non-monetary information, expressed in physical units (kg, t, m³, etc). PEMA is: an analytical instrument that allows identifying the environmental strengths and weaknesses; a support technique of the environmental decisions; a tool of direct and indirect control of the environmental consequences; a tool that provides a neutral and transparent basis of internal communication and, indirectly, external; a tool for promoting sustainable development [3]:

As can be seen from above, management accounting is not just about the monetary standard, but presents information in terms of a natural standard also, having the ability to reflect environmental costs that the entity has to cover in order to prevent, treat or repair damages that the activity of the entity has caused to the environment.

5. Conclusions

From the presented information, it can be noted that lately, the development of accounting has focused on environmental accounting, and new sub-fields of it have started to develop, such as environmental management accounting and environmental audit. In terms of the researches conducted in Romania regarding environmental accounting, they are still in their early days, but there is a definite interest for this field. Considering the intense normalization and standardization process in the field of

accounting, it may be noted that in terms of environmental management and environmental protection there is considerable effort also to achieve a joint representation of these types of activities, by establishing standards that regulate environmental issues, like in the case of Bulgaria, where there is an international standard regarding environmental accounting, called "Reports on environmental regeneration", which approaches environmental issues. In Romania, due to Order 3055/209, the involvement of accounting in covering environmental aspects has begun to be felt.

According to IFAC (2005), implementing environmental management accounting within an entity may bring a series of benefits, such as [5]:

- *Promoting environmental protection in terms of compliance with environmental regulations in force and complying with self-imposed environmental policies within the entity by:* planning and implementing pollution control investments, investigating and seeking substitutes for toxic materials, reporting emissions and waste to the regulatory authority;

- *Supporting costs' reduction and minimizing the environmental impact through an efficient use of energy and resources:* the accurate monitoring of energy, water, materials and waste flows, assessing the benefits resulted from investments in eco-efficient activities;

- *Supporting the assessment and implementation of efficient environmental programs that support the long-term strategic position of the entity:* designing green products and services, estimating internal costs generated by the change of regulations;

- *Helping management to identify and record hidden environmental costs.*

By separately managing environmental costs, by identifying the cost bearers and generators and by using cost-sharing basis and adequate costing methods, we may conclude how important is the implementation of environmental management accounting, which may contribute more efficient processes that generate costs' reductions and increased profitability.

The presented information and conclusions provide opportunities for new approaches regarding environmental costs and the implementation of environmental management accounting within entities in order to ensure continuous environmental performance and to reduce environmental risks.

Access Database Using ASP Technology

Stancu Ana-Maria Ramona
"Dimitrie Cantemir" Christian University
ana_maria_ramona@yahoo.com

Abstract

ASP (Active Server Pages) is a technology created by Microsoft to create dynamic web pages, which is based on storing and executing scripts on the Web server and ASP.NET is an evolution of the ASP based on a new technology developed by Microsoft, and more specifically platform. NET Framework. ASP technology. NET ASP which bring significant improvements.

The paper shows the ASP technology, which includes articles and features underlying its functioning.

Besides our technology, we also present ActiveX Data Objects (ADO) that provides access to databases within Web pages.

Key words: ASP, script object

J.E.L. classification: O 30

1. Introduction

ASP is a technology used to create dynamic Web pages providing access to online applications.

2. ASP technology

Active Server pages technology (ASP) is developed by Microsoft, allows scripts for server and is used to create and run the Web applications.

An ASP page is a file stored on a Web server and has the extension. ASP. This special extension distinguishes between an ASP page and a normal HTML file which has extension Html or Htm.

When a user visits a Web site and requires a normal HTML file, the server simply takes over the file from your hard disk or computer memory and sends it to the user's browser.

The browser interprets the Html file content and the visitor will see the Web page.

When someone ask for a normal Html page, the Web server is not interested in the content file. The Web server's role is limited to the correct file download without processing it. All the interpretation work for the file content is carried out by the user's browser.

On the other hand, when someone ask for an ASP page, the Web server will have a more active role.

Before sending the file to the user's browser, it is first processed by the Web server. The latter interprets and executes any scripts from an ASP page, before it is sent to the user's browser. Due to the fact that an ASP page is processed by the server instead of the browser, such a page is compatible with all Web browsers.

ASP pages containing scripts server-side. As script generation language, you can use Microsoft Visual Basic Scripting Edition (VBScript) or Microsoft Jscript or PerlScript.

Microsoft Jscript technology company includes ASP PerlScript is not a Microsoft product.

Script generation languages such as VBScript differ from complete programming languages, such as Visual Basic and Java, by the simplicity of rules and their syntax. For example, VBScript does not require the declaration of variables as particular types of data.

Moreover, unlike Visual Basic or Java, ASP page should not be compiled into a separate file before it can be executed.

When you modify an ASP page, it is automatically recompiled for the next request.

The advantage of using a language generation scripts to build up web pages is that it facilitates the modification of a Web site even after it was released on the Internet.

If you discover an error in this site, you can quickly load page in Notepad or Wordpad program which will solve the problem.

However, we should not conclude that if an ASP page uses language generation scripts then the Active Server pages are slow or do not provide necessary coverage .

ASP scripts run in the same process as the Web server and can be divided into threads. This allows an ASP page to provide simultaneously ,in an efficient way , support to a large number of users.

An ASP page would be strictly limited if it could contain only scripts. The exact time or other interesting posts might be shown, but it wouldn't be possible to acquire information from users, to store data in a database or create files on the server. Fortunately, an ASP page can contain server-side components.

A script for the server begins to run when a browser requests an ASP file on the server. In turn, the server calls ASP processing your requested file and executes each command in the script, then send to the browser page.

In order to create the ASP file one can use any text editor, but it is advisable to support ASP environment such as Microsoft Visual Studio or Macromedia Dreamweaver MX2004.

A component is something that usually has methods, properties and collections.

Component methods determine the actions they can perform with an object.

Component properties can be read or set in order to establish the component state. Collections of components are sets of key and value pairs referring to the component.

Active Server Pages are two types of components: objects that can be included and components that can be installed.

The six items included in Active Server Pages are:

- Applications – is information that can be shared among all users of ASP applications.
- Object Context - this object is used in ASP pages dealing transactions
- Request - all information is sent to the server browser, including form variables and query strings.
- Response - is all the information sent from a server to a browser, including HTML content sent by an ASP page.

- Server – the server allows the use of different utility functions

- Session - represents the information on this particular session of a user.

Active Server pages include a special set of objects, ActiveX Data, which allows accessing a database from an ASP page. These objects are used to insert, update and delete rows in a table.

The objects can be used also to retrieve a set of records from a table and display them ai an ASP page.

Features

- Distribution through a network. ASP site provides access to online applications - either by Internet or a private network.

- External control. Instead of making the location of each user, the application administration and maintenance is carried out externally, from a central location, by the ASP provider. One-to-many service. ASP model was created as a one-to-many. Normally, ASPs provide standardized applications or with a minimum degree of customization to a large number of customers, which provides a financial advantage due to the minimal costs of implementation.

- Compliance with contract. An ASP assumes responsibility for access to application distribution mechanism including related services. ASP's support, supervise and monitor the distribution mechanism operations under a contractual agreement to the service.

ASP runs on these servers:

- Microsoft Internet Information Server (IIS) version 3.0 minimum running under Windows NT Server 4.0;

- Microsoft Peer Web Services 3.0 running under Windows NT Workstation;

- Microsoft Personal Web Server that runs under Windows 95.

Accessing databases is done with the help of ActiveXData Objects (ADO) which is an extensible and easy to use technology that allows access to databases whitin Web pages.

ADO can be used to write scripts compact and scalable in order to connect to databases through ODBC (Open Database Connectivity).

Basically, ADO can be used for compact writing scripts with a view to connecting to data sources from Web pages or OLE DB compatible data sources, while ADO is used

as databases, spreadsheets, sequential data files, or e-mail directories.

Before you can open a connection to a database, ASP page will need to provide physical location information database.

In order words, the script should provide method of finding the database on the hard disk.

This can be done with the help of a data source name (DSN Data Source Name-).

There are two different types of data source name. If you create a source file name (File DSN), information about connecting to the database will be stored in a file. If you create a name of source system information about connecting to the database, it will be stored in the computer's registry database.

There are no special reasons which require the use of one or other type of data source name. Both types work equally well, but I used in my application one system data source name.

OLE DB is a programming interface that provides system-wide standard set of COM components for database management. Accessing the COM component object model is achieved by using ADO and using VBScript or JScript scripts we can access databases from Web applications.

ADO is used to open databases ODBC (Open Database Connectivity).

In order to establish and handle connections between application and OLE DB compatible data sources and databases compatible ODBC, ADO provides Connection subject. It has properties and methods that allow open and closing the connections to databases, as well as formulating queries for updating.

ASP works with objects and, in order to be able to use these objects, they must be initiated by the program. ASP provides five no instantiate objects: Response object can be used to send data to the client. Contains methods: Write (send the information directly from the browser), redirect (send to a URL), ContentType (controls the content type sent by the client), cookies (assign unique values to identify the customer).

- Server Object ASP executes control environment;
- Session object contains information on the work sessions open by the client web server;

- Application object contains comprehensive information about the application that can be accessed by many clients;

- Object Request allows retrieving the values that the client's browser transmits to the server during an HTTP request.

ASP Code includes:

- Native ASP commands, access Active Server objects and engine components;

- Scripting commands have a clearly defined syntax in which the script language type that is used must be specified .

Scriptures are of two types:

- client-side scripts are scripts that are executed and interpreted by the browser and which access the objects available in the browser;

- Server – side scripts are provided by ASP for IIS and also allow including ActiveX components.

The most striking features of the site consist of ASP interaction with databases that become very accessible by using the Active Data Objects, developing complex applications at the server that is programmed in ASP or application level session and Active Server exploitation as well as Active Server IIS server components.

3. Conclusions

Microsoft Active Server Pages (ASP) is used to create dynamic and interactive Web pages. An ASP page is a page that contains script commands that are processed by the server before being sent to the client browser.

Distributed Database Design

Stancu Ana-Maria Ramona
"Dimitrie Cantemir" Christian University
ana_maria_ramona@yahoo.com

Abstract

BDD systems show a number of advantages mainly related to the system performance increase by reducing costs relative to processing and transmission of data and, last but not least, to the fact that BDD system better fits in the organizational structure of an economic unit. The disadvantages are related to the high complexity of design applications). If your DBMS does not provide facilities for handling distributed conflicts, they will have to be dealt with through applications,. This is more difficult for such a system which, besides the complexity of a computer network, has problems related to the data distributed processing, as well as ensuring a high level of transparency of the distribution.

The process of achieving a BDD system is complex and generally justified in one of the following situations: when conducting large database, which provides support for most activities in an organization, where frequent extension of the existing system or interconnecting a set of existing database are expected.

Key words: databases, distributed design, design methods.

J.E.L. classification: O 30

1. Introduction

Distributed databases are controlled by a database management system baazelor data.

2. Transaction database

A distributed database (BDD) is a collection of logically related data shared, physically distributed over a computer network. management system of distributed

databases (SGBDD) is a software system that allows BDD managing and makes its distribution transparent to the user.

Distributed database systems are meant to address "information islands." They have emerged as a necessity, especially for computer network, to support data management when they are found physically in different parts of the network..

The first systems were distributed database Ingres / STAR, a distributed version of Ingres, SQL*STAR distributed version of Oracle and R* distributed version of DB2.

Among the requirements that a distributed database system must provide, we mention: local autonomy in organizing and processing data, not using a centralization of records and data, the possibility for sites to work continuously, independently of changes in working configurations (adding or removing sites), location independence and data fragmentation (physical transparency), potential for replication (copying) and independence of copies, distributed processing of applications, distributed transaction management, independence of hardware, operating system, network management system and database.

A SGBDD consists of a single database that is split into fragments, some fragments may be multiplied, and each piece or copy is kept on one or more sites under the control of a local DBMS. Each site is capable of processing user queries in the local system, independently of the rest of the network, or is able to participate in the processing of data in other sites in the network. In order to say that a SGBD is distributed, there must be at least one global application.

Transactions in a distributed database are classified into local and global transactions according to the sites their execution require.

A network configuration is a distributed database if the different sites are "aware" of the existence of other sites and if each site offers an environment that can run local and global transactions.

Physical system (network) which is supported by a distributed database may consist of personal computers, Minicomputers, Workstations, etc.. all linked in the network and generically named sites.

We can restate our original definition saying that a distributed database system consists of a collection of sites, each of them being able to participate in carrying out transactions which access data one or multiple sites.

A SGBDD has the following characteristics:

- contains a collection of shared and logically related data
- data are divided into a number of fragments
- fragments can be reproduced
- fragments / reproductions are allocated to sites
- sites are linked in a communications network
- data from each site under the control of a DBMS
- DBMS system of each site can handle local applications autonomously
- each DBMS system participated in one global application global at least

Benefits distributed databases:

- distributed system is best modeled on the organizational structure of many organizations, considering that many companies are located "distributed" geographically
- data are shared, but their management has a high degree of local autonomy
- Database availability is obviously better than if centralized. If the system indicates some errors in the system at local level, the entire system can continue function in satisfactory condition
- system reliability is improved. It can quickly restore damaged files by using replicas located on other sites
- data processing performances improve by enabling parallel processing of queries

A distributed system provides economic advantages if we compare the costs of implementing and maintaining a network to the appropriate costs of a similar centralized processing power system. Lower costs can also be obtained if more local processing are carried out (the system accommodate and permit applications). In the same way, it is more convenient to "adjust" a computer network to the organization needs (if [for example it is necessary to add additional sites) than a central computer with similar power.

The system's modular management capacity allows its extensions or settlement of some partial "failure" without affecting too much (sometimes without affecting at all) on-going activities throughout the distributed system.

Among the distribution disadvantages, we mention the increased complexity of such a system.

This is a major disadvantage arising from some disadvantages "consequence" of which:

- it is more difficult to manage and develop a distributed system
- Costs related to such systems are much higher than those related to centralized ones. More time and more specializes staff are necessary at the level of system design and implementation. Both things require higher costs in terms of money. To these costs can be added those which arise from the necessity of ensuring performing hardware and the software necessary software . Similarly, if the systems are operated at normal costs, quite costly communications will have to be added
- increased error potential. A series of errors such as, for example, those generated by distributed algorithms can be added to the common errors which occur while working with databases
- additional processing is required due to the exchange of messages between sites and their coordination in general
- it is more difficult to ensure the security of a distributed system than of a centralized system. Data are more readily available to unauthorized persons as one may try to access them through access between computers. Control at physical administrative level has less weight than for a centralized system.

- Data integrity is also more difficult in a distributed system. Integrity is often expressed in terms of restrictions (rules, conditions) that the database needs to check. Due to the high cost of communication (time and money) one sometimes gives up some rules at the expense of consistency database checking .

- lack of standards. We cannot speak of a total lack of standards but work with distributed data systems is still not based on generally accepted international standards. Hence disadvantages such as: communication problems which arise due to the fact that fixed standards and widely accepted communication standards and protocols for data access have not been yet established yet. There is not enough experience concerning distributed work and design are concerned; it is more difficult to manage and operate a distributed system than a centralized one.

Another disadvantage that I can mention here is the emergence of a large flow of information between sites and hence the need to solve problems such as synchronizing, detection and correction of disturbances, the elimination of redundancies due to inconsistent, etc..

Types of design. BDD design can be done, just like the central database, in top-down and / or bottom-up manner :

- Top-down design aims to ensure optimum data distribution and is used when designing BDD start from scratch. Generally, top-down approaches result in consistent systems.

- Bottom-up Design of BDD is recommended if there are local database to be integrated into a unified system. In this case the main objective in designing the BDD is to ensure the best possible cooperation between the existing databases which are usually heterogeneous.

- Mix design, partly top-down and respectively partly bottom-up is recommended in most cases because it responds better for practical situations.

3. Conclusions

Distributed database is a database management system controlled by a database in which storage devices are attached in a more distributed computers.

The Cluster Approach for Facilitating Romanian Firms' Access to the European Single Market

Stănculescu Anca-Maria
Gagea Andreea Mihaela
Academy of Economic Studies, Bucharest
sam33ro@yahoo.com
andreeagagea@yahoo.com
Niculae Tudorel
Ministry of Administration and Interior
niculae.tudorel@mai.gov.ro

Abstract

The article analyses the possibilities for facilitating Romanian firms' access to the European Single Market through clusters development and internationalization. Having considered the clusters' role and characteristics, in order to determine their potential for growth and internationalization and the implications at a national, regional and firm level, this potential is analyzed in the context of the European Single Market.

The cluster approach in the Romanian context, as status-quo and possibilities for development, is analyzed considering the specific policy, institutional and economic framework, providing recommendations for appropriate measures in order to greater benefit from the clusters' potential and the opportunities provided by Romania's integration in the European Single Market structures.

Key words: Clusters, Cluster policies, European Single Market, Internationalization.

J.E.L. classification: F23, L22, O33.

1. Introduction

Cluster-type agglomerations have been a socio-economic reality even before the Industrial Revolution, drawing the attention of well-known researchers like Marshall, who noted the tendency for specialised firms to be concentrated in "industrial districts", or Schumpeter, who noted the innovative potential of cluster-type phenomena in his

now highly influential exposition on the role of entrepreneurs and the "creative destruction". The fundamental changes in the economy, leading towards a knowledge-based economy and society, have determined the proliferation of clusters - considered as organizational forms specific to the knowledge economy, with enriched potential, functionalities and characteristics.

Clusters and cluster policies have begun to arise special interest in the last decade of the 20th century, which has grown substantially in the last years, in order to accomplish the competitiveness demands at a national, regional and firm level in the emerging knowledge economy. Clusters intercorelate the constitutive firms in an integrated system which provides higher possibilities concerning the access to knowledge and information, costs reduction and innovation, thus contributing to the economic development of the region where they are located.

2. Clusters' role and characteristics

The cluster concept has been introduced to the attention of both analysts and policy-makers by Michael Porter in his highly influential analysis of the competitive advantage of nations ([15]), which is presented as resulting from the interactions of four forces which compound the competitiveness "diamond" - factor conditions, demand conditions, firm strategy, structure and rivalry, and related and supporting industries. The last of these points toward the importance of location and offers an explanation for the well-known success of

Silicon Valley in electronics, or Hollywood in the film industry.

Porter also developed a widely-used definition: "Clusters are geographic concentrations of interconnected companies, specialised suppliers and service providers, firms in related industries, and associated institutions (for example universities, standards agencies, and trade associations) in particular fields that compete but also co-operate" ([16], p. 199).

Approaches to cluster vary, focusing especially on elements like *location*, *industry* or *innovation*; a common element is the inter-firms and other organisations linkages, which provide economic value to clusters. There is a shift of focus from a firm-level to an inter-firms approach. In the context of the knowledge economy, it is well recognised that industry specific knowledge is becoming cumulative and embedded in a particular region or area rather than in a specific firm ([3], p. 322). Clusters largely resulted from the opportunities for economic transactions between firms, explained by Porter in terms of "*economies of agglomeration*" ([16], p. 213); however, concerning the latest generations of clusters, the emphasis has shifted to *learning and knowledge access*.

Location, or geographical proximity, has been greatly emphasized, however, it is not sufficient for a cluster development, as geographical proximity facilitates but does not guarantee effective inter-firms interactions. Actually, progress in information and communication technology has allowed for the creation of *virtual clusters*, at an international level and based on emergent technologies, which create and share information and knowledge across great distances. Clusters may also be viewed as networks of firms with complex interactions, but they differ from networks in that they integrate firms linked in a value chain, as an alternative way of organising the value chain ([17], p. 80).

Clusters can be very different in terms of density, social cohesion, level of activity, vitality, industry concentration, geographical area and stages of development. It is worth mentioning a general classification which allows for an analysis of a cluster's *development stage and possibilities*, thus distinguishing between: *potential clusters* - that present good opportunities for

development and where some key elements of an effective cluster are already in place, *latent clusters* - with an high number of firms but where the level of interaction among them is still low due to lack of trust, low cooperation and high transaction costs; *working clusters* - well developed industrial districts ([4], pp. 99-129).

Clusters' role as competitiveness and innovation promoting mechanisms is largely recognised. Among the many clusters specific *competitiveness-generating advantages* that mark their proliferation tendency can be counted: inter-firm cooperation at lower costs, higher innovation possibilities for persons or organisations, dissemination and lower costs and risks for research and development activities, higher technical, economical and organisational flexibility, shorter periods of time for manufacturing, lower unit costs due to scale economies at the cluster level, etc. ([11], p. 187).

Clusters' *innovative potential* is mostly due to access to knowledge and information, new technologies, business concepts, etc, and to flexible organising, as an essential characteristic of clusters ([14], pp. 400-405), which allows for a quick efficient reconfiguration of its activities. OECD specialists have actually suggested a cluster approach as a "reduced national innovation system", as clusters incorporate the main requirements for promoting innovation ([2], pp. 673-709).

3. Clusters development and internationalization on the European Single Market

Clusters can facilitate the *internationalization* of firms on the one hand, through the benefits offered to members, and, on the other, through initiatives at a cluster level. Specific barriers to internationalization, regarding managerial, financial, informational and competition-related issues faced by firms can be substantially reduced by a *cluster membership* ([10], pp. 529-554). Firms' competitiveness is enhanced through the external characteristics of the cluster, such as cost advantages due to proximity, joint marketing, reduced costs of access to competent personnel and information, etc.

Positive externalities of the clusters thus determine the members' growth and competitiveness, and participation to a cluster will have a positive impact on their internationalization. Clusters may thus become a platform to boost self internationalization of firms.

Cluster based initiatives for internationalization have become more numerous and wider in recent years, although traditionally, the focus was on the internal activities related to improving the business environment at a cluster level, strengthening the links between participants, and modernizing the members' strategies and transactions. International cooperation between clusters and between clusters and other actors is a strong impetus towards internationalization for the firms within the cluster. Also, we can say that it is a way to prevent one of the main cluster limits - and networks in general - namely, *the lock-in effect* ([8], p. 109), which occurs when a firm is over-embedded with existing cluster partners and fails to broaden its network horizons with other prospective partners and to identify potential business opportunities beyond the cluster boundary. Smaller firms are more likely to be locked in and subject to inertia in clusters due to their liabilities, whereas firms that are larger and better positioned within the cluster may often exercise stronger power upon smaller firms.

Cluster based internationalization may take different *forms*, among which the most common approach is *establishing contacts* with other networks and clusters. This may include facilitating knowledge and experience exchange, for example by mutual providing of information and mutual exchanges of staff. More advanced forms of international cooperation are *partnerships*, by sharing support services and access to facilities like research and development centers.

The growing importance of establishing international relations between clusters is due to the changes in the global economic environment in which clusters operate. Reducing barriers to trade and investment, and technological changes have determined decreasing transport and communication costs, and thus have created opportunities to *break the supply chain at a geographical level*. The efforts for fostering

internationalization have been mainly directed to increasing income from exports, but the focus is currently shifting to creating and sustaining competitive advantages through international cooperation. As a result, clusters tend to specialize on their core competences, which further leads towards a growing integration of clusters into global supply chains.

We may argue that the *European Single Market* actually creates additional pressures for the development of the relations between clusters. National borders continue to distinguish between the European markets and the competitive environments, by political, administrative, legal, cultural barriers. However, the efforts to consolidate the Single Market and, particularly, to eliminate the obstacles to the free movement of goods, services, capital and people, act as strong incentives for international cooperation between clusters. European clusters can not rely solely on the natural forces which determine the agglomeration of firms, attraction of capabilities and assets, as do, for example, the clusters on the U.S. market, with a higher level of integration, but this may be offset to some extent by promoting and strengthening international cooperation ([5], p. 50).

Fostering clusters development and internationalization is an important axis of the Community Programs, particularly circumscribed to the territorial cooperation objective of the Cohesion Policy, but also as a way of promoting innovation in the Lisbon Strategy. Key measures for cooperation between European clusters in specific areas of coverage include: the *European Cluster Policy Group* - cluster policies, the *European Cluster Alliance*, under PRO INNO Europe - cooperation at the political level, the *European Cluster Observatory*, under Europe INNOVA - European clusters analysis, *European Innovation Platform for Clusters*, under Europe INNOVA - fostering innovation, the *European Excellence Cluster Initiative* under PRO INNO Europe - quality of clusters management ([6]). Europe INNOVA is a European initiative which aspires to become the laboratory for the development, testing and promotion of new tools and instruments to support innovation, with a view to helping innovative firms to innovate faster and better. PRO INNO

Europe is an initiative of Directorate General Enterprise and Industry which aims to become the focal point for innovation policy analysis and policy cooperation in Europe, with a view to learn from the best and contribute to the development of new and better innovation policies in Europe.

4. The cluster approach in the Romanian context

In Romania, the general approach to clusters can be described in the way that the national level has been "too high", whereas the local level has been "too low" ([1], p. 214). The institutional framework for regional economic development includes the Regional Development Agencies, created in the late '90s of the last century ([21]). Clusters began to be mentioned in the national strategic documents in the context of Romania's integration in the European Union, as a priority related to the economic development and integration into the Single Market structures. However, no national cluster specific institutions or policies have emerged so far.

Considering the proportionality between the quantity and quality of knowledge circulating and spilling over between the firms within a cluster and the cluster's size, level of specialization and the extent to which the locality or the region is geared towards and focused upon the industries comprising the cluster - which also appears in the literature as the cluster dominance ([18], pp. 104-130) - the European Cluster Observatory proposes an indicator that measures the specialised critical mass' to develop positive spill-overs and linkages for each cluster by assigning each cluster a number of stars for each of the three criteria. Thus, *size* is measured by the number of employees, *specialization* - compares the proportion of employment in a cluster category in a region over the total employment in the same region, to the proportion of total European employment in that cluster category over total European employment, and *focus* - relates employment in the cluster to total employment in the region.

In the case of Romania, according to this methodology, the identified clusters appear as shown in Table 1. and Table 2:

Table 1. The main clusters in Romania by stars, employment and specialisation

Cluster	Region	Employees	Specialization	Stars
Apparel	Nord-Est	53 835	6.64	***
Textiles	Nord-Est	45 786	5.62	***
Apparel	Centru	42 396	5.65	***
Apparel	Sud-Est	41 401	5.65	***

Building Fixtures	Sud-Muntenia	23 113	2.12	***

Source: European Cluster Observatory, ISC/CSC cluster codes 1.0, Dataset 2007/06/06.

It can be argued that in Romania, the existing clusters have a relatively low level of specialization, but have a significant number of employees at a regional level. Among the main clusters in Romania, and also, among the oldest ones, can be mentioned especially those of the North-West and West regions, which have been created mostly due to foreign investments from Italian clusters beginning in the early 90's of the last century. The main industries of Romanian clusters are: apparel, textiles, building fixtures, communications, oil and gas, metal, automotive and footwear.

In what concerns the regions comprising the highest number of stars, according to the European Cluster Observatory, the Centre and South-Muntenia regions are primarily noted.

Table 2. The main regions in Romania by total number of stars and share of employment in clusters with stars

Region	Total number of stars	Share of employment in clusters with stars
Centru	27	71.25%
Sud-Muntenia	26	71.43%
Vest	22	62.53%
Nord-Vest	19	63.06%
Sud-Est	17	77.59%
Nord-Est	17	60.47%
Sud-Vest Oltenia	15	50.75%
Bucuresti-Ilfov	15	54.92%

We may argue that clusters are a relatively recent phenomenon in Romania - which emerged in the early 90's of the last century, in the context of the transition to a market economy - clusters are few in number and unevenly distributed across Romania. Thus, their capacity for association, cooperation and coordination at national and international level - which should be inherent to their development, as it can be argued, for example, for Italian clusters - is reduced. Moreover, because the phenomenon is relatively recent, cluster specific policies and institutions at national, regional and local level have not yet sufficiently emerged. Hence *the need to adopt specific measures and instruments for the development and internationalization of Romanian clusters*.

The potential of clusters as engines for the economic development at regional and national level is widely recognized. Clusters are also effective ways to conduct efficient policies, as firm-level interventions are too costly and tend to distort competition, while policies directed at broad industries will tend to have little effect and may miss the critical levers. Clusters can help to identify opportunities and threats in the business environment affecting the whole economy, and they can be the testing "laboratories" for adequate solutions addressing them. Clusters can also help the private and the public sector policy making by facilitating collaboration and joint action along a wide set of players ([9], p. 19).

The need for intervention by policy measures for clusters promotion in order to prevent some negative effects of the market mechanisms meets several arguments, including the non-appropriability of positive externalities, lack of location information, lack of coordination of members, restrictions on firms' mobility, negative externalities ([12], pp. 34-35).

The development and internationalization of clusters requires *coordination at national and regional level*. Clusters literature particularly points to the importance of national policies, but in order to obtain superior knowledge and greater adaptability to the conditions of the region, it is essential that these efforts be coordinated at a regional level, and this is especially important in a country with a relatively weak state such as Romania ([13], p. 4). The cluster approach has yet to be mandated at the level of central government, and the measures should further be adapted and varied according to the characteristics of clusters.

5. Conclusions

Clusters are acknowledged instruments for providing competitiveness, access to learning and knowledge, innovation and growth at a national, regional and firm level. Clusters can facilitate the internationalization of firms on the one hand, through the benefits offered to their members, and, on the other, through initiatives at a cluster level. Clusters development and internationalization is an important axis of the Community Programs, while the characteristics of the European Single Market provide strong incentives for international cooperation between clusters.

Romania's integration in the structures of the European Single Market provides specific opportunities for Romanian clusters development and internationalization. Clusters are a relatively recent phenomenon in Romania, with a reduced capacity for association, cooperation and coordination at national and international level, but there is potential for a cluster approach which can be used for facilitating Romanian firms' access to the European Single Market. Applying the cluster approach in Romania requires the adoption of specific measures and instruments for the development and

internationalization of Romanian clusters and coordination at national and regional level.

Abstract

The article analyses the possibilities for virtual enterprises development and facilitation on the European Single Market, with a special emphasis on the case of Romania, as new Member State of the European Union, which can use this possibility to quicker and easier involve in the Single Market. Virtual enterprises are organizational structures of the knowledge economy, with great potential for development in the near future. Their characteristics, as well as advantages and limitations are considered, in order to identify the issues and the appropriate measures related to their development and facilitation in the context of the European Single Market and Romania.

Key words: Virtual enterprises, Virtual enterprises policies, European Single Market, Internationalization.

J.E.L. classification: F23, L22, O33.

1. Introduction

The virtual enterprise - or virtual organization - is a concept launched in the early '90s of the last century, in order to describe the effects of the electronic business development (e-business), based on new information and communication technologies, which resulted in radical structural changes in the economy, both inside organizations and in the relations between them. A virtual enterprise is a new

form of the relations between organizations in light of these developments.

A virtual enterprise can be described as a group of enterprises which come together in an integrated network to share skills, competences and resources in order to better attend market opportunities, with the support of the information and communication technologies. It envisages the creation of an organizational forms which allows for a synergetic combination of the partners' core competences to achieve maximum consumer satisfaction.

2. Virtual enterprises - organizational structures of the knowledge economy

The central element that characterizes the "virtuality" of such organizational forms is the ability of the enterprises to offer a complete product to consumers for which it does not have all the necessary competences, the others being achieved through cooperation. In this way, each enterprise can bring a contribution inside the partnership in order to produce more complex but also more customised goods and services ([7], p. 6).

Virtual enterprises can be best described by their main *characteristics* and in this respect may be referred: the focus on core competences, a single point of contact with customers, the international dimension, independency, low formalization, the systems provided by information and communication technologies, temporariness ([4], p. 16).

Each of the partners in a virtual organization focuses on their *core competences*, their complementarity allowing

for the achievement of synergy. Virtual enterprises' competitiveness is therefore primarily due to an advantage of differentiation - because the current market requirements call for a diversified portfolio of high skills, but also for cost reduction for different processes - based on distinct competences, technology, and a rational division of labour between the partners. The focus on core competences enables the cooperation with other enterprises for the non-core competencies. Virtual enterprises are therefore a dynamic combination of core competences, thereby meeting market requirements in terms of efficiency and effectiveness, rapid response and flexibility.

Virtual enterprises' support systems are based on *information and communication technologies*, which allow for overcoming the problems of geographical distance between components and facilitate coordination at low communication costs. Advances in information and communication technologies can also be considered as the main element that enables the creation and development of virtual enterprises. Such support systems allow for the development of intensive communication processes between the enterprises, at a maximum speed.

The products or services created within a virtual enterprise are provided by a *single point of contact with customers*, which can be a trademark or an enterprise focused on sales which acts on behalf of the entire organization. From the customer's point of view, a supplier that provides the whole offer is more attractive than several small businesses which must coordinate, and the customer doesn't need to know its suppliers or partners.

Virtual enterprises do not have a common area where the employees are located, and so the network can expand with no geographical restrictions, in several different countries, the *international dimension* being actually considered implicit for the virtual enterprises. This is a significant advantage in a globalized business environment where the international presence of a business is becoming increasingly important. At the same time, geographical distance still holds an important place, even if it has become insignificant for transmitting information, it remains an important factor for the timely supply of

resources and the production of goods and services.

Although they have joint activities, the partners within a virtual enterprise remain legally and economically *independent*. A virtual enterprise aims to combine resources and expertise in order to better exploit business opportunities, with no merger of their internal structures. This creates a fluid organizational system that allows for flexible recombining of resources. However, we can still argue the co-dependency that comes from the cooperation of the enterprises, in the sense that each of them depends on the performance of the others.

In order to achieve flexibility and response speed, the enterprises do not adopt a hierarchical, formal organizational system, and the relations between them are characterized by *low formalization*, oriented towards value creation. Virtual enterprises are characterized by rather informal relations based on mutual trust.

Virtual enterprises are regarded as *temporary networks*, quickly set up in order to exploit a specific market opportunity, which can disperse afterwards, reconfiguring into other forms, according to the new emerging opportunities. Such flexibility enables enterprises to form systems that can respond quickly to the current market requirements and to dissolve after the requirements have been met.

These characteristics of virtual enterprises have undergone changes over time, both in terms of economic reality and conceptual approach, although they are relatively new organizational forms of the contemporary economic environment. Thus, the focus on core competences remain an essential coordinate of the virtual enterprises, but *there is a tendency towards long term cooperation, with higher levels of formalization, and the international dimension is not necessarily essential*. Also, *information and communication technologies and a single point of contact with customers are more and more applied on a medium level*. The emphasis is on *creating and maintaining stable networks, on the basis of specific policies* ([4], p. 28).

3. Virtual enterprises development and facilitation

There are many *advantages* of developing such organizational forms, that derive from the characteristics of the virtual enterprises. The focus on core competences enables competitiveness and costs reduction. Being built upon systems based on information and communication technologies which facilitate fast data transfers and coordination within the company at low costs, with no geographical and temporal boundaries, virtual enterprises enable efficiency gains for all activities. The possibilities of rapid and competitive reconfiguration of resources in order to respond quickly to market opportunities provides flexibility and speed of response to market requirements.

At the same time, virtual enterprises have some *limitations*, among which should be mentioned especially the current, still insufficient level of technological capacity and affordability, which hinders a full integration of the virtual enterprises, that are wholly dependent on the quality and transparency of electronic information exchanged between the partners. This has implications on the distribution of profits, costs reduction, strategies and policies, information privacy and intellectual property protection. Although virtual enterprises do not imply hierarchical relations, the dominance of the enterprises from its core may appear. Another problem is related to regulations, including those regarding electronic contracts, taxation, monopolies. Virtual businesses do not fall under the classifications provided by law, and production can be placed anywhere the law is more favorable.

Facilitating the creation and development of virtual enterprises must consider each stage of their *life cycle*, which can be defined in the following steps:

- *Creation* - the initiation and constitution of a virtual enterprise, by an enterprise or a group of enterprises, which have seized a market opportunity and carry out a strategic plan for the operation of a virtual enterprise in order to exploit it;
- *Operation* - Execution of operations within the defined scope of the strategic plan;

- *Evolution* - The context of virtual organizations is rapidly changing which lead to a continuous evolution of the virtual enterprise, within the current strategic plan;

- *Metamorphosis or dissolution* - based on the experience gained during the functioning as a virtual enterprise, its components may choose either a metamorphosis into a new virtual organization by changing its form, with the establishment of new goals, or for its dissolution ([2], pp. 529-542).

Corresponding to these steps, the creation or participation in virtual enterprises, from the point of view of their management, as distributed economic processes, requires, specifically:

- *Creation of a virtual enterprise* includes: *forming a virtual enterprise* (development and announcement of the distributed economic processes, search for potential partners, receipt of proposals and selection of partners from the negotiation phase to the legal agreement) and *modelling the virtual enterprise* (coordination of the distributed economic processes);
- *Operation and evolution of a virtual enterprise* includes: *management of the distributed economic processes* (evaluation, measurement, simulation and monitoring of the distributed economic processes, from technical, human and socio-legal point of view), *supervision* (reconfiguring a virtual enterprise by inclusion or exclusion of members, changes to the contract regarding the distributed economic processes like rescheduling or cancellation) and *dispute settlement* ([8], p. 34).

At each of these stages a number of specific issues arise that may prove problematic for creating or participating in virtual enterprises - from the firms' perspective, or for their facilitation - from a regulatory and institutional perspective.

4. Issues in virtual enterprises development and facilitation on the European Single Market and Romania

Virtual enterprises require a *specific environment for development*, beyond the general trends of globalization and dynamism of the business environment. The *U.S.* is the reference model in this respect, as environment for the emergence and proliferation of such organizational forms, as far back as in the late '90s of last century being reported over 250,000 virtual enterprises ([7], p. 2). This can be explained by the fact that the *U.S.* is already constituted as an integrated market with a fluid social structure, individualism and autonomy in operation. We may argue that the *European Single Market* does not fully meet the features of the *U.S.* market as an enabling environment for the creation and development of virtual enterprises, especially due to the lower integration and still higher administrative and regulatory uncertainties. However, the progresses towards a full integration, and, especially, the specific efforts to create a favourable environment for the virtual enterprises, enable their creation and functioning, an aspect of great importance especially for the new Member States like Romania, which can use this possibility to quicker and easier involve in the Single Market. The worldwide efforts to boost virtual enterprises are most visible in the European Union, and among the programs with specific measures in this regard can be mentioned: the European Strategic Program on Research in Information Technology - ESPRIT (1983 - 1998), Information Society Technologies - IST (1999 - 2006), Information and Communication Technologies - ICT (2007 - 2013), International Scientific Cooperation - INCO (2002 - 2006 and 2007 - 2013). One of the European Union projects, the European Collaborative Networked Organizations Leadership Initiative - ECOLEAD, conducted between 2004 and 2008, put as a vision that "in ten years, in response to fast changing market conditions, most enterprises and specially the SMEs will be part of some sustainable collaborative networks that will act as breeding environments for the

formation of dynamic virtual organizations" ([1], pp. 3-32).

In the case of *Romania* is primarily proving problematic what is in fact a prerequisite for the existence of the virtual enterprises, namely, the *availability of information and communication technologies*. The issue of its implementation in *Romania* is hindered by both objective and subjective factors, including the lack of the specific information and communication technologies infrastructure at national level, underdeveloped communication networks, still high costs for communications services, weak informatization among the economic organizations, lack of the specific culture in informatics among the employees, resistance to change ([3], p. 131). We may assert that in *Romania* the introduction and use of information and communication technologies is still incipient, which does not repeal, however, the possibilities for the *Romanian* enterprises to adopt organizational structures such as virtual enterprises, provided the appropriation of the necessary infrastructure. Issues fall to a more general level, respectively, achieving the *Romanian* knowledge society, which, providing the adoption of a correct management, and especially, consistent efforts of the decision makers, can become reality.

In the creation of a virtual enterprise, a key issue is *identifying the appropriate partners and establishing relationships with them*, both for the initiating enterprise and for those wishing to join a virtual enterprise. Conclusion of contracts can be a complex, long lasting process, from the first contact phase to the negotiation phase and the reach of an agreement. This is a problematic issue, and one of the solutions proposed is the use of electronic institutions have all the information needed to identify potential partners, act as a broker, facilitating negotiation, contract validation, monitoring and enforcement, building members' reputation ([5], p. 18). Building such institutions is still a desideratum, as there are many problems to be addressed in this regard, like for example, related to the development of an open and flexible support infrastructure, allowing for use on a wide variety of platforms, the ensuring of data safety, confidentiality and veracity, or the establishment of a uniform regulatory

framework, based on certain standards of conduct which need to be set out.

The possibilities for virtual enterprises development on the European Single Market remain primarily related to the *firms' networks*, of either high or low formalization. The projects at the European Union level trying to facilitate such networks can also be an opportunity in this respect. The existing relationships between companies, especially long term ones, can offset these difficulties, actually incorporating a degree of flexibility. In this case, contracts are not necessarily required, and business opportunities can be exploited as soon as they appear.

Mutual trust is fundamental for the existence of virtual enterprises, as it acts as a substitute for two critical factors, which are often missing in a virtual enterprise, namely, the hierarchical control associated with traditional organizations, which rarely can be found in a network of independent firms, and the legal framework to regulate the formation, operation and dissolution of the organization, much less developed in the case of virtual enterprises, since long contract negotiations could reduce or even cancel out the positive effects of a fast-reacting virtual enterprise ([7], pp. 8-9). Mutual trust results from an expectation of fair behavior and a level of understanding of shared business practices, which is facilitated by closer interactions than those usually found in a virtual enterprise, as well as a common history, which also is not a feature of a virtual enterprise. Thus, mutual trust is a factor influencing the trend of formation of stable, long term virtual enterprises. In any case, mutual trust plays an important role for the electronic business in general, which, despite the issues of trust that they may involve, have seen a spectacular development.

The regulatory framework for virtual enterprises in the European Union is that regarding the information and communication technology services, including the protection of intellectual property, distance selling, electronic commerce, electronic money, electronic signature. Of special interest for virtual enterprises is the *Directive on Electronic Commerce* - whose main provisions are transposed into Romanian law by *Law no. 365 of 7 June 2002 on Electronic Commerce*

([16]) - which sets out the main rules of conduct for virtual business, like the requirement of transparency concerning information about the organization for the customers. The *Directive on Distance Selling* - which has as Romanian counterpart the *Ordinance no. 130/2000 on the Legal Regime of Distance Contracts* ([17]) - influences the activities of virtual enterprises as it introduces a number of regulations, particularly regarding Business-to-Consumer type sales. The *Directive on Electronic Signatures* - with its corresponding *Law no. 455 of 18 July 2001 on Electronic Signature* ([15]) - is of particular importance for the virtual enterprises, confirming the validity of distance contracts between the participating firms.

We cannot assert, however, that there is an integrated regulatory framework for virtual enterprises on the European Single Market, as there still are a number of legal concerns regarding, for example, legal representation - in the sense that within a virtual enterprise, its components remain independent as a legal entities, which raises the question on how a virtual enterprise could and should be constructed legally. In practice, the members can found an association for each project, or establish a leading firm acting as a legal entity, and the other participating firms receive the status of sub-contractors.

5. Conclusions

Virtual enterprises are organizational structures of the knowledge economy having as main characteristics the focus on core competences, a single point of contact with customers, the international dimension, independency, low formalization, the systems provided by information and communication technologies, temporariness. There are many advantages that derive from such characteristics, among which flexibility and response speed, which motivate the efforts for facilitating their creation and development.

In the context of the European Single Market, the integration of markets, and, especially, the specific efforts to create a favourable environment for the virtual enterprises, enable their development and facilitation in all the Member States, which can use this possibility to quicker and easier

involve in the Single Market. Issues related to virtual enterprises development and facilitation include: availability of information and communication technologies, identifying the appropriate partners and establishing relationships with them, building networks, achieving mutual trust, developing an integrated regulatory framework.

We may argue, in any case, that virtual enterprises are still a nascent form, but with substantial development potential in the near future on the European Single Market, along with the progresses towards integration as well as regulation and institutionalization. They can also be an effective possibility for Romanian enterprises to gain access on the Single Market, on the condition that the related difficulties can be successfully overcome, as a specificity being mentioned that they would rely mainly on such informal relationships developed by firms.

Specified of Substantiation of Administrative Decisions of Investments

Stignei Pasa Veronica
"Spiru Haret" University of Constanta
veronica_stignei@yahoo.com

Abstract

The decision-making process specific at public investment is a set of activities and operations involved with all decisions of the three stages of public investment. Complexity of specific public investment decision-making process leads to the idea that the achievement to be part of different entities having different responsibilities and objectives and including different methodological activities.

Key words: administrative decisions, public investments, public investments management

J.E.L. classification: G28, H76

1. Introduction

The purpose of this paper is to define the concept of decision making and analysis of its specificity in relation to public investment. Throughout the paper stated the main objective, the entities involved in its realization, and decision stages, broken down by main phases, which mostly correspond to the stages of public investment: the allocation of funds for public investment, public investment and their operational implementation. Were treated and main failures that can occur in decision making and how they affect the efficient use of public funds. It analyzes the actions of lobbyists on public investment decision and action on the design and efficiency of public investment through their impact on growth.

2. The decision-making system

Administrative decentralization process profoundly changes the terms of reference and are chosen targets set based options and decisions. Local agent acts as a component of a political environment and administrative

decisions are the product of local origin-specific variables, which central government can not collect them. The quality of decision making in influencing public institution reduce costs through better management of all categories of resources to meet increasing public interest.

The decision-making system in public institution includes the entire through which improves the satisfaction level of public interest and thus its social mission. Diversity causes grounding system of social needs of different types of decisions. If political decisions are the choice of a legal action more politically possible to achieve the proposed objective, policy decisions require a comprehensive analysis of impact studies to identify a variant of public policy that will lead to solving public interest issues raised on the public agenda.

Customizing, administrative decision is the choice of a rational process of decision alternatives, the more possible to achieve the government target. Administrative decision can be defined as a manifestation of the will of an organ of government in which he opts for a solution that would enable the achievement of a goal. It is important to know that a decision must contain the following: factors affecting the choice of a number of solutions, selecting one of at least two variants, the existence of one or more objectives to be achieved and the presence of one or more decision makers. Adopt an investment decision involving the local government from those anticipated that triggers investment, but these expectations may be compromised by events whose sources are multiple, but SIU contingencies. Financial analysis allows a rapid assessment of risk. Activity takes place under the influence of the authorities a degree of uncertainty generated by economic and financial environment, requiring a greater adaptability and flexibility.

In the literature circulating and the sense of overall decision-making activities aimed at decision making or not a particular public investment, which I consider the definition too narrow and unable to shape the image of particular importance and complexity of public investment decision-making process. Specific decision-making process at public investment is a set of activities and operations involved with all decisions of the three stages of public investment.

Making a parallel with the three steps required in the distribution of public funds (inventory needs, prioritizing needs and quantification of needs) we could say that specific public investment decision-making process begins with the decisions involved in allocating public funds for current expenditure or investment, determine the costs of competing destinations investment, the decision to perform or not a particular investment decisions and continues until the stage of implementation and operation of investment, including those aimed at controlling and measuring the effectiveness of that investment.

Regarding specific major objective of public investment decision-making process, given the complexity of this concept, it becomes difficult to distinguish the overall objective of public finances namely the allocation of public funds with maximum efficiency to increase welfare citizens. But he does not relate to all allocations of public funds on public policy but only on that part of the allocation and use of public resources that relate to public investment. Concerning the efficient allocation of public funds, this means obtaining the maximum social benefit from the use of resources, taking into account both benefits and costs of monetary and non-pecuniary those that are significant for public investment.

The complexity of decision-making process specific public investment leads to the idea that the achievement to be part of different entities having different responsibilities and objectives and including different methodological activities. I believe an analysis of decision-making bodies, decision-making levels and steps required to achieve a public investment in the paper.

3. Entities involved in decision making process specific at public investment

The particularity of decision making to private sector projects is given by the existence of a unique player, "public entity" (government), the initiator of the project. The analysis of the concept of public investment decision-making process shows that at each stage of the investment and depending on the political and administrative features, there are a wide variety of public and private entities that can contribute to public investment decision making. Depending on the powers of the political system in Romania and the level of interest for public investment, allocate decision will be taken by the legislative (parliament or local council) or the executive (mayor). At the legislative level, involvement in decision making is to determine the exact destination for investment funds, or provide their absolute amount. The administrative decision is in fact an out-put of work of civil servants, citizens and administrative structure of the collaboration between departments.

The public entity decider on the exact use of funds for public investment notes that for each type of investment can partly determine the specific optimal way. The tradition states that allocate decision for most large public investment in Romania is the central power. Data analysis shows, however, that for certain categories of public investments, transfer to local government allocate decision efficiency gains lead to debt, according to experts, higher capacity needs of local deceleration. Decisions at the central level, even if the same lump sum, often lead to oversupply of public services in some regions and shortages in others, resulting in inefficient allocation of public funds. So, one of the reasons for the differences between the perceived utility of using variants of a public investment in centralized or decentralized system is the cross-effects of consumption. Therefore, promoting investment in decentralized system generates little effect on neighboring regions, but leads to a better allocation of resources locally.

Funds received from the European Commission ^[2] determinate that the decision

of allocation of local public investment belongs to a particular destination. In this connection, the effectiveness of using such funds and whether the decision at European level show that it is very important to define precise objectives and using those types of investments best suited to them. Thus, the objective of reducing disparities between EU regions is not well met by allocating a larger part of the funds for road infrastructure, because it usually takes just the most developed regions of countries with lower economic development level of the EU. Such investment has a powerful effect on per capita GDP growth, but mainly leads to the development of regions rich in the less developed EU, increasing interregional disparities within the same country.

A special issue on the most appropriate entity to allocate decision on public investment is the degree of development of local or regional government, and its degree of autonomy granted her experience to cope with managerial decision-making activities involved. The question arises acutely in the case of emerging countries where infrastructure and local public awareness and implementation of appropriate management procedures do not always transfer to local decision.

Some allocate decisions can be taken on public investment and public agencies established for that purpose (ex. SAPARD Agency in agriculture). In general, they do not imply a particular difficulty or unexpected implications, being confined to limited areas. Note that for certain types of public investment, public education can be a right for endorsement or approval just wish it meets the criteria of efficiency in public investment.

Specific public investment, allocate decision is not the only type of decision in decision making. In the implementation phase it can belong to the same or other public entities. Compliance with the efficiency criteria imposed detailing procedures to be followed such as public bidding, with regular reporting requirement of efficiency indicators, etc. It also important is monitoring and enforcement of quality standards and deadlines for implementation in this phase.

For the operational phase, the fundamental decision is the choice of entity responsible for operating and maintaining the investment. Exploitation shall follow the same criteria of efficiency and accountability will be clearly defined public entity in terms of control because this is the phase where the real benefits occur for citizens. A common solution recommended by the theory and practice specialty is to develop public-private partnerships, particularly in the operational phase of the investment. At this stage, local government or entities responsible for acts as representatives of citizens who have legitimate decision by voting, but there can assist decision by other entities. Most important, analysts believe that there are public policy role to play in achieving basic and reliable assessment of the effectiveness of public investment and provision of data for public policy makers (but still have work to counseling). Others may be employees of public institutions responsible for implementation of public investment, through the power of unions.

A thorny issue in the optimal choice of entity decision is redundant responsibilities more entities from different decision levels, which leads to hinder decision-making and loss of efficiency (ex implementation of public investment is made by local governments, but funding from the government).

4. Stages and binding activities of public investment decision making

The steps are: first public resources for investment, which includes a series of activities required to ensure that conditions of efficiency. Thus, the first phase is an inventory of its citizens by decider authorities (local government). Arrangements for obtaining data for this goal are manifold, and the decision on choosing the best power must take into account information gathered data: public consultation survey, brainstorming or analysis of past allocations (the first three have the great advantage of give a clear picture of the needs of citizens, but the costs are relatively high and requires the active participation of citizen-voters). Last

involving low levels of cost, but would lead to inefficient allocation of funds, confusing the past with the efficiency of expenditure (previously allocated funds were used, and hence the public service was required). Scientists recommend priorities transparent and objective selection criteria. Not be forgotten in the course of decision the rank of priority, to satisfy urgent needs.

The second phase is the planning of public investment, leading to complex decision making, organized in several directions. It examines the basic situation needs to prioritize public investments. Then make decisions on spatial planning (geographical location) and temporal (time required for implementation of the investment) and socio-economic planning is investment. Next phase is prognostic of budget, where is estimated the cost of public investment, financing and timing of payments. The prognostic of budget of public investment may be in the system of capital budget projects and budgets. The literature recommends the second option because it gives the best prerequisites for the application of efficiency criteria.

The second stage is the execution of public investment. Public decision-makers must choose providers of execution, which can be public or private. The choice of procedure is usually done by public auction or public procurement procedure suitable to the nature of investment. In recent years, increasingly more decisions in the second stage refers to the type of resources used, a procedure often used as private fundraising through public-private partnerships. Also in this stage is important and control decisions related to the calculation of efficiency indicators during implementation, the relevant timeframe. Efficiency analysis can reveal whether abandonment even execution.

The third stage is the exploitation of public investment, beginning with the decision on how the operating entity and investment (public or private provision of public services free or not, etc.). Important for making the decision on the operation of public investment is to calculate the activity of ex-post efficiency indicators, representing the feedback of the investment, but also a

knowledge base for future public investment. At this stage, decisions are to operational service.

For ensuring that the administrative decision with maximum efficiency purpose, it must meet certain requirements, the most important being ^[1]:

1. To be scientifically proven, legal and social (scientific validity of the decision provides relief practice, routine, chance, improvisation, subjective, but at the same time to comply with the requirements of citizens);

2. To be the result of the management team and to stimulate citizens' initiative. Modern management determine teamwork, the leader (mayor) has acted as a catalyst. In general, the team must attract and citizens in the foundation and making decisions.

3. To be pragmatic and simple. (Any administrative decision should have a practical use, so it is necessary to complete a comprehensive assessment and socio-economic situation of the administrative-territorial unit, taking account of specific local and national issues, simplicity increases execution efficiency and leads to a logical progress).

4. To be appropriate. (Administrative decision must be taken by the body at the right time, knowing the local administration bodies at local social needs better. It is noted that in taking decisions, local authorities take account of normative acts issued by central government which, in turn, is consult directly with local representatives).

5. To be systemic in nature. (Administrative decision will be integrated into administrative decisions taken previously, thus vanishing overlaps and contradictions between different decisions. The character of the system ensures consistency of administrative decision, administrative decision being determined by the particular content and participants in decision making. The administrative decision is output of the civil servants, professionals, citizens, and collaboration between the departments management structure).

The peculiarities of the administrative decision are:

- is a complex process that requires a lot of work, extensive research and documentation directly, but better meet citizens' demands;
- socio-political in nature (Management objectives are determined by political power);
- is the result of more people work and collaboration between employees in different departments of administrative structure;
- endorsed by one or more persons responsible for the legality of the decision and realism;
- is characterized by high degree of diversity and difficulty;
- makers have relative autonomy in the decision process indebted of regulatory framework in which the activities;
- in formulating, is the only logical approach is science approach, because it provides the possibility of forming a fundamental point of view that takes into account all the problem, to avoid superficiality and subjectivity;
- Decision-making transparency is a feature that creates the opening act of public participation in governance.

5. Problems in public investment decision making^[3]

Public decision-making process involves a series of elements of subjectivity, which may give rise to disturbances which strongly affects the efficiency of public investment to which it relates. The most common are: poor management or an unrealistic view of the effects of public investment, electoral manipulation or influence of various interest groups.

A poor management decision-entity at any stage in the implementation of public investment induces inefficiency risk on decision-making and implementation of operational risk, which leads to inefficiency.

Unrealistic vision of decision makers in different phases of public investment The literature identifies two types (Boardman) ignores the prudential than monetary costs and benefits, eliminating external ones so that some worthwhile projects are rejected

and the showing the spenders trend to consider and some the project costs as benefits, which artificially enhances the efficiency parameters of accepting risk inducing inefficient projects.

Manipulating the election - the public investment decision-making process is effective to the extent that its purposes are the creation of additional capital capable of being operated effectively and lead to increased welfare. There are times when it is likely interfered with the electoral purposes. Manipulating the election would have to disappear as a phenomenon by increasing the rationality of voters, but the reality proves otherwise, which only leads to increased sophistication. In this regard, candidates promise not increase public spending but also change their structure to focus on the voters want, increasing investment costs and lower current expenditure. The ability to not only be an election slogan and thus lead to deceleration is difficult to streamline decision making specific public investments. Other possibilities for the use of public funds for investment in employment for political purposes is too large amounts for projects that do not represent voters' preferences at the end of the mandate to limit political freedom to choose his successor in terms of financing and other investment programs leading to the continuation of projects already commenced, without the development of public investment in the preferences of voters. Practice shows that the method is used in a situation where politicians are aware of the very low chances for getting a new mandate.

Interest groups, "association of persons formed to communicate their preferences to public policy makers, influencing decisions by exerting pressure (represented by unions, employers' associations, environmental organizations, each with very different kinds and sizes and different means). Their action can be considered legitimate if their purpose is to highlight the public policy maker voter preferences. But it can also have adverse effects in terms of allocate efficiency of public facilities because they want some. There are such mechanisms depending on the type of influence on decision makers:

- dominant interest group (the public pressure on policy makers meet for a single interest held by a dominant group, other groups with insignificant action)
- conflict between two dominant groups (the same decision-maker is under pressure from two opposing interest groups. The situation is counterproductive for the lack of reconciliation of objectives leads to a policy of public investment is not optimal)
- variety of interests (the pressure of several groups, each with its interests, independent of each other. The power of these groups is weak, but public policy makers have the advantage of identifying the preferences of the electorate)
- dominance of political parties (political parties where voters support preferences)

6. Conclusion

The overall conclusion of the study is that it is absolutely necessary to comply with ethical requirements, legal and practical for the proper conduct of specific public investment decision-making process so that the objective of an efficient supply of public goods resulting from the investment process can be achieved.

Communication Potential of Fidelity Cards

Stoica Ana-Maria
„Spiru Haret" University of Bucharest,
Faculty of Marketing and International Economic Business
anasta84@yahoo.com

Abstract

The loyalty card represents an excellent communication method for the improvement of the clients' loyalisation because it permits the immediate answer by making possible the accomodation of the offer to each customer. These types of cards are efficient from the viewpoint of both the measurable and the estimated present effects and for the relatively reduced costs together with a short time for application. The cards may be a long term solution and an instrument of marketing at the disposition of the producers or companies that wish an efficient way to stimulate the increase in sales.

Key words: loyalty cards, client, database
J.E.L. classification: M31, M37, M39

1. Introduction

Successful companies approach a new attitude to the market materialized in the customer care, considering that the business can survive only if it motivates them and manages to satisfy their needs in order to enhance their loyalty to the brand. In this respect, a fundamental role in a company is played by the development of customer relationship skills and by the ability to adjust to the requirements of a changing dynamic market.

The loyalty card is used as a tool to retain clients in order to continuously improve the firm's activity aimed at establishing a sound connection between the two parties involved. A characteristic feature of modern economic life refers to long-term sales, which are an effective way for gaining and maintaining competitive advantage, the firm acting in a global market place by enhancing economic relationships with the customers, including the satisfaction of their needs and their retention.

2. Some aspects concerning the loyalisation programs based on cards

Analyzing the slow rhythm of the economy upgrading, one notices fundamental changes in the area of consumers who act on short term regarding the purchasing of products accessible from the price point of view, this being the most used element of the marketing mix, which lays on the basis of purchasing decision. Consequently, the tendency of loyal customers that is based on the price label does not present any restriction regarding the selection of a cheaper product.

A fundamental feature of the market economy consists in the determinant influence of the human factor, which is permanently in the situation to choose. In the current context, the efforts for the fidelity of clients and drawing of potential clients for the company, an excellent sale strategy, which consists in establishing a strongly positive correlation between the brand and the client on a longer period of time.

In this situation, the most of the companies organize fidelity campaigns of clients, built around the fidelity card, representing for the traders a real marketing instrument, a viable fidelity alternative and sale promotion. These types of cards are important for the successful business by two reasons: on the one hand, it is manifested as essence in generating profitably for the client for the company without appealing to big discounts that diminish the company incomes, and on the other hand, the efficiency of integration program may be evaluated by the pursuance of feedback received from the clients, which gives you the possibility of collecting a large range of information, which helps you automatically to build data bases that may be further used in the training of the different marketing campaigns.

More and more companies are mainly oriented to the market and implicitly they stress the maintaining and development of clients. The basic idea is the establishment of a unique relationship with the consumer, this being evidenced on the first phase on the care to the client and further in an analysis of his/her needs.

The main role of such a card consists in the segmenting and targeting of consumers, respectively their selection, having as purpose a better allocation of resources that lay on the basis of a good operation of the organization. Taking into account the schematic presentation of the type of client, of the behavior of possessors of these cards and their reaction to promotions, one may notice their loyalty towards the one who issues such cards, a process that evidences from the time when the consumers interacts with the fidelity card. This type of card offers you the opportunity of selling products additionally.

From the point of view of the holder of this type of card, it grants him the possibility of benefitting from advantages at the purchasing of the products of the issuer company or of its partners, consisting in significant discounts, priority to the acquirement of products being in the promotional campaign and reception by different occasions of presents from the company, as well as the accumulation of points depending on the value of acquisitions, points that transform into value checks by the aid of which you may choose other types of products. The measurement of efficiency of a fidelity campaign of clients using the cards has as index the number of offered cards.

The clients use this kind of card because it gives them the possibility of participating to special promotions and competitions addressed exclusively to them, offering them something that is not available for non-participant clients. Consequently, this being the best reason to purchase more often other products of the company, too, the temptation of making purchases under the impulse of the moment is much bigger. In many cases, not necessarily the volume of discounts matters, but the fact that rather it creates at the level of the level of customers' perception the sensation of belonging to a well defined social group.

The main advantage for the one who issues such cards is the fact that it identifies the client and allows the collection of data with a personal character, which may be processed and may be introduced in the data bases, being used in other marketing campaigns, too. In fact, this type of card represents a means of obtaining the essential information about what the client bought, more precisely regarding the behavior of consumers for the purpose of maximization of the trading actions. But, for the most of the times, it is used to be able to notice who are the loyal clients, what products they acquire, where the purchasers will be placed and when they will want to buy, which makes that the trader to regard his/her business through the long term value, more precisely of the final result, this being oriented towards the market needs and the clients' needs.

The tendency of the loyalty program is towards identifying patterns of integration with Customer Relationship Management systems which are manifested by a more efficient communication. In this situation is allowed the passing from communicating advertising materials or launchings of products on mail way, at their communication by mail, is followed the extension of the range of benefit granted to the customers because could determine an increase of the performances and appearance of multi-brand cards. In the actual context, on the inland market the loyalty cards are under the form of multi-brand, which underlines the creation and management of certain profitable relations with the customers by accepting partnerships with a number of non-competitive companies. Is obvious that, dividing the loyalty support is a method which allows the reduction of maintenance expenses of the loyalty program, a strategy well chosen for attracting new customers. In these conditions, as partner or associate companies may take advantage from an extended database, together with the one of other brands.

Loyalty cards are centering the satisfaction and knowledge of the customers' needs, is important what is selling but also to who is selling, as a consequence, allows the acquisition of information about each customer. The cards may be an instrument of marketing at the disposition of the producers or companies that wish an efficient way to

stimulate the increase in sales. Is needed to maintain ourselves competitive in the age of discounts for consolidating the relation with the existing customers, delighting them by meeting their individual needs, in the idea of customizing the offer and inviting them to discover new things for transforming customers that are satisfied and un-satisfied in loyal customers . But many times helps you to remove rapidly and efficiently the merchandise remained on stock and to get to know better the reasons for which customers are buying your products. It is used as a communication mean which every company must have in point and apply it both in the organizational development and for improvement of the business relations.

Collecting data based on studies performed in distinct places and periods demonstrates that is a lot cheaper to keep an existing customer that to attract a new one. The customers are constituting the main advantage of any business, but still the attraction and conquest of the buyers, respectively customers, and, furthermore, keeping them, are of a decisive importance. „The high satisfaction degree or delight are creating an emotional affinity with the brand, not just a rational preference. The result will be a high degree of loyalty [1].”

The positive impact of implementing such cards al market level has in consideration not necessarily an increase of the number of buyers, as a loyalty of the ones already existent, by which we reward the most worthy customers granting them more value. Also, it represents for the customer a way to make savings within the budget meant for acquiring products by promotions, granted discounts, grace period, in another words, it demonstrates a high efficiency in the activity rendered. As a consequence, it highlights on the one side the positive features on which we can connect for believing in its success and on the other side the determining factors which influence the buying decision.

3. Conclusions

The basic principle of this paper is providing a conceptual framework for studying and putting into practice of the loyalty card, as well as the development of profitable customer relationships. We also outline the description of the concept of loyalty card and the creation of structural links with the most important clients. On the one hand, this analysis emphasizes the firm's competitiveness against the background of a broader horizon of future action of the parties involved in the sales/buying processes; on the other hand it involves a change in the mode of action of the firm on the market. The principle that a profitable business must take into account the customers bears a significant influence upon the activity of the enterprise. The most valuable partner is a loyal constant customer that brings middle-incomes to the firm, than a high income one who performs one single transaction. This comparative approach is feasible because of the possibility of using databases, with the help of which customers are identified and continuously monitored with regard to their purchases.

The Role of Organizational Identity regarding Change Management

Stoica Camelia

Alexe Gheorghe Adrian

Dima Niculina

"Valahia" University of Targoviste

camelia.stoica15@yahoo.com

alexeghad@yahoo.com

eduapa92@yahoo.com

Abstract

Managing change is always problematic, because it affects both human resource management and the managers. This paper is addressing the question of identity, both individual and organizational, redefining the strengths and limitations in the life of the enterprise and not least, considering the vectors of identity. Also, the identity is presented in the context of change management. The definitions of the identity in management are multiple and we are not presenting here a review of the literature but a pragmatic definition, which will allow the reader to understand the concept and above all be able to put it into practice.

Key words: management strategies, resistance to change, change in organizations.

J.E.L. classification: M19

1. Introduction

To orient the reader towards the general concept of identity, we can refer to the works of Roland Reitter [7] which approaches this concept. For a sociological view of the phenomenon, we can relate to the work of Renaud Sainsaulieu [6] or to that of Raphael Gely [5].

The word "identity" derives from the Latin word "identitas" with the meaning the "quality a specific thing" derived from "idem" which means "the same." Thus, the identity, at an etymological level, seems to have an antinomic character regarding change. But in reality, it is not necessarily like that. If in the case of the Renault-Nissan merger [1], an experience readily accepted by

the Japanese people (known for its strong identity), perfectly illustrates the fact that change management is not necessarily incompatible with the concept of identity.

A major change does not necessarily mean a complete change. Total change does not exist in management because the process is too costly. It is preferable to recreate an organization from scratch. Consequently, in terms of switching is better to make an identification of what may or may not change, then to undertake an activity to verify the identity elements that influence both the organization and how people operate there. In the case of Renault-Nissan, the changes in doing certain activities of production and distribution have not reinvented the identity of Nissan, which remains clearly under the influence of the Japanese.

2. The functional definition of identity

2.1. Key Characteristics of identity

If the first definition of identity emphasizes the absence of incompatibility between identity and change, however, does not sufficiently illustrate what identity means in practice and whether it can prevent or facilitate change. The trajectory of identity applicable to an individual, group or organization can help us find a possible answer to this question.

Fig. 1. The trajectory of an individual's identity

The identity of an individual is represented by an arrow to emphasize its dynamic character. Indeed, a person's identity is constantly evolving, as determined by the tastes, desires and ambitions and the people he meets, the experiences, knowledge and the risks he/she assumes. All these criteria are either individuals or the environment in which it operates, but they are far from being statistics, but are at the basis of the constantly changing nature of identity. Thus, we face a paradox: the identity at the semantic level makes us think of the "one who is just alike". This could leave the wrong impression that all concepts are incompatible with dynamic identity. In fact, the "quality of the one who is alike" should mean that in an identity, the individual remains coherent, evolving in some stage before adapting to the environment, its needs and desires. This notion is entirely evolutionary close to what Mauss [4] or Bourdieu [2] have called habitus. A sort of "structured structure", personal to each individual, which allows both the incorporation of experiences which he is experiencing and also the interpretation of social structures. Without this unique habitus, the individual will not know how to react, and if it will remain the same, he will be lost in absurd actions. The habitus allows the understanding of the consistency of the approach or the conservation of identity in an evolving social environment, thereby ensuring its survival.

What Bourdieu [2] called "primary and secondary socialization", are identified clearly, as family and school. The individual's confrontation with the extreme challenges of the organizational environment (crisis, unemployment, exclusion) can position him beyond the "structured structures", for example in a context characterized by a strong identity discomfort.

Here are a few big trends in regard to identity issues referred in recent findings [8]

Professional identity problems have almost always an impact on personal identity (the characteristics of personality and family relations, friends and even neighbors.)

An unemployed person who has no role in society, is easily prone to have low expectations.

Increasingly, many employees think that if they do not have the chance to put their skills into practice today, they will lose their status in the organization (constraint to change).

Those who look for a job feel victims of a system over which they have no control over. They refuse even more the change.

These developments, do not make it easy for those working in the field of human resources or for the managers who want to implement change. In fact, in a context like this, change becomes synonymous with danger. But individuals are not the only ones who have suffered as a result of this turbulent environment. Companies are also aware of the volatility of change and this is observed since the early 60s [3]. Consequently, we can apply this trajectory of individual identity and the organization.

2.2. The trajectory of the organization's identity

Paul Ricoeur defines identity as "a narrative, an unfolding of the self, a temporary ongoing". This definition takes into account the dynamic nature of risk and identity, preserving the notion of a coherent whole. But individuals encounter, throughout life, certain events, which mark their professional career. Even organizations go through sequences of events, some of which are historical. Thus, sometimes an individual's identity trajectory can be superimposed on the trajectory of the organization's identity.

Figure 2. The path of the identity

When we talk about organizational identity, we refer to the duality of personal identity and professional identity, which leaves place for the dualism between the social object and the task of the organization. Concordance between the two types of identity will allow to maintain, over time, the coherence of organizational identity.

3. Vectors of identity: two essential key points to change

As the expression "with one swallow we can not consider that spring is here", the change actor should not confuse a change of identity with an important event, whatever its importance or seriousness. An identity is always based on time and the change actor should not be influenced by current events, even if they seem decisive for the future of the organization.

Human resource management or even the manager who must develop or face the effects of change, must recognize that above the apparent phenomenon of speech that is often excessive, a distance must be kept. As Francois Mitterrand said: "We need a less involved approach".

It is important for human resource management to avoid all questions related to judgment values (eg.: This event is dangerous for the future of the enterprise?). This type of question leads to a defensive emotional response, it will not help the manager in the process of change. Although the manager has a duty to listen to various speakers whose argument is based on judgment values, he must not be influenced by this vision. The fact that some managers are recognized as members of the group, will make them lose their objectivity that initially was more visible. The hardest part is keeping a certain distance from the event, on the other hand, this distance should be kept and should be extended also to the people who deal with the event. Referring to the company's values or by reference to certain routine activities to certain myths, symbols and structures, the manager will see himself included in an intrinsically collective dynamic of the group that will help him cope with the situation. Organizational identity is such an important asset for human resource

management or managers confronted to change.

4. The binomial change-aspirations in the psychology of change

Organizational identity is formed based on the dynamics of the balance of power between employee's aspirations, namely, the nature and extent to which they are subject to change.

Depending on the degree of compatibility between change and aspirations, there are two major types of change: change in accordance with the aspirations and changes in conflict with the aspirations.

Any change that complies with the aspirations, desires, expectations, needs, dreams and our ambitions is integrated almost immediately. In fact, we do not live this as a change but rather as a chance or feel it as a reward for our efforts.

The way we look at change often lacks objectivity, because we lose sight of the fact that one of the fundamental laws of change always involves the element of losing the previous state of facts. Therefore, even if we worked to get a change, this will not necessarily give rise to, a sense of satisfaction. It is the case of some people who have worked to achieve an almost immediate promotion and tend to almost regret it. The subsequent rejection of the desired changes, is called the "Faust' syndrome".

In general, we adapt very well to changes that we've desired, even if consequences or side effects may appear, especially if they are minor. Integrating change, in accordance with our aspirations is sustainable if the case when the side effects are of lesser importance than the desired effects. The case is striking in terms social ranking, be it economical, political or artistic.

The central element of success is not a myth but a law from the perspective that it corresponds to the change, even if it bears a substantial gain it is always accompanied by a loss. However, the change is irreversible. This is particularly striking in the relational plan: never change a relationship that will not return to its original state. A man who was fired will not see an "employer" in the same way as

before. Similarly, a single mistake will not be forgotten. Therefore, even a desired change is not part of a final integration.

Changes in contradiction with the aspirations are required, proposed, announced even if they do not expect or desire them. These changes will be incorporated only after a process of decomposition in several stages: denial of the situation, strengthening, decompensation, resignation and integration.

The duration and intensity of each phase depends mainly on two factors: emotional distance that puts us in touch with what is changed and the "expected" distance which separates us from what is changed. Emotional distance is seen through the attachment to our built and virtual reality while expected distance translates, in turn, into our capacity to imagine the possibility of such changes.

A principle will result in relation to change: as the emotional distance is even shorter the expected one becomes longer and the change process is more difficult.

If a change has a powerful and unpredictable emotional impact, the integration process of this change is compromised. Our survival instinct allows us to rationalize the event several times, so that it becomes bearable. Extremely, this type of rationalization is neurotic or worse, psychotic (total rejection of reality shared by others, breaking the contact with the world).

In contrast, when the emotional distance is long (the subject is poorly attached to the subject of change) and the expected one short (subject imagines that such a change may occur), then the process of change is fast and painless. Long emotional distance associated with a short expected one is called indifference.

The duration of each phase depends also on the personality and experience of the persons involved. The more we build our own realities on rigid plans (strong beliefs, strong values, strong ego) the less we have experimented change and have more difficulties to adapt to it.

Our point of view regarding the world around us associated with our emotions, characterizes our ability to embrace change, therefore, causing differences in responses to change. Whether the fact that the expected distance is short or long and that its valence (the term derives from experimental psychology and means that the attributed value of an object or a situation is used to motivate ones attraction or rejection) is positive or negative.

5. Conclusions

An organization, today, can easily change the field of work, especially taking into account the extremely rapid technological fads. However, the field of activity is stored as an expression of talent, expertise, and not least the structural framework of the organization.

Profile of the ECO-HOTEL Market in Romania

Sztruten (Lefter) Gina Gilet

Academy of Economic Studies, Bucharest and Romanian American University
lefter_gina@yahoo.com

Abstract

In order to develop a study for the hotel market profiling Romanian ecological was undertaken with direct reference to the current state of development of eco-management system implemented in the hospitality business in Romania. The analysis undertaken concluded that currently there are only three ecological certified units, two by national eco-certification authorities and one unit TUV certified. The three units are hotel Saturn from Romanian Saturn seaside resort, Crowne Plaza Bucharest and Vega Hotel in Mamaia resort.

Key words: eco-management, hotel, environment, eco-label.

J.E.L. classification: L 83

1. Introduction

Presentation of the three eco-systems management approach became paramount in determining the eco-hotel market profile.

Introduced after 2005, eco-labels are a hotel's environmental performance certification, configured by 20 criteria that include, among others, indicators of the ecological materials used, presence and quality of vegetation within the perimeter of the building, energy and water consumption, waste disposal and recycling effectiveness of cleaning systems, information on ecological preventive behavior and so on [5]. Fee for obtaining this certification is currently 200-300 Euro per year.

Eco-label awarding criteria for tourist establishments are regulated by the Government Decision no. 1855/2005. The regulation implements the European Commission Decision no. 287/2003/CE establishing ecological criteria for the award of community eco-label for tourist accommodation services, published in the

Official Journal of the European Union European Communities (OJEC) No L12/2003.

The label is a voluntary certification that was created in 1992 by the European Commission to encourage the market for "green" products. It is granted after a review of the characteristics of the product or service and is valid for a period of 3-5 years.

2. Ecological certified hotels in Romania

The eco tourism services accreditation is simple because it relies on self declaration by many shareholders.

2.1. Crowne Plaza Hotel Bucharest

Crowne Plaza Hotel Bucharest is part of the Crowne Plaza Hotel Chain, chain belonging to hotels group IHG InterContinental Hotel with outstanding brands, such as InterContinental, Hotel Indigo, Holiday Inn, Holiday Inn Express, Staybridge Suites and Candlewood Suites.

Hotel chain Crowne Plaza Hotels & Resorts is a brand found in over 50 countries worldwide, mostly in urban centers, specializing in business hotel services, offering businessmen comfort and services of superior quality.

Ecological certified. Crowne Plaza Hotel Bucharest is the second hotel in Romania that received on November 4, 2009 the right to use the European Ecological Label - Ecolabel. European Eco-label created by the European Commission in 1992, is a single certification scheme to help consumers to distinguish green products and services, Crowne Plaza Bucharest Hotel enrolling as among the companies that contribute to maintaining a healthy environment and reduce global pollution.

The process of obtaining the label was neither short nor easy, the hotel managed to get 46 points from the 16.5 necessary.

The objectives were mainly concerned on decrease consumption, eco-style training of staff, raising awareness and promoting a "green attitude" among customers, suppliers and business partners.

Although initially not designed to save energy, the hotel has undergone a series of renovations to be labeled ecological. Used water comes from its own well drilled to 192 m. This will save water. Crowne Plaza Bucharest currently carrying out a national program "Conserving for Tomorrow", which encourages tourists to think and act in the spirit of ecology[6].

Hotel investors have realized the importance and economic benefits of a more responsible towards the environment approach, architectural design, renovation and management benefits of green building. Using intelligent systems for buildings means energy savings with up to 30% of all integrated and controlled facilities of a building automatically. Fruitful collaboration between design teams, plumbing, electrical, design and investors to achieve an ecological hotel led to the implementation of innovative solutions for the hospitality industry with regard to energy efficiency, renewable energies and punctual solutions to reduce environmental impact in the operation phase of the hotel.

Ensure 112 non-smoking rooms (representing approximately 70% of the total available rooms) is one of the minimum criteria for environmental labeling. Starting from the premise that the green stands for quality, the hotel has enough green space, sustainable solutions for the development of green areas, where water consumption is reduced.

In order to improve air quality all conference rooms enjoy natural daylight and are situated on the ground floor with direct access to courtyard gardens.

Creating a Green Team with the role of implementing green initiatives in the hotel network or to initiate a program of "customer awareness" on environmental behaviors during accommodation, fully demonstrates the merit of obtaining the EU Eco-label.

2.2. Vega Hotel

Hotel Vega is part of the Upetrom Group and classified 5 stars. Located in Mamaia, Hotel Vega was completely renovated over a period of two years and opened on August 8, 2008. The consolidation work and modernization have led to an investment worth 13 million euros, in addition to building value amounting to 2.5 million.

Overview of Hotel Vega Mamaia: Feng Shui principles of harmony governs the hotel in a very high level and discreet. Not disparate components and kitsch, but its layout, color inspiration from elements of Feng Shui, the arrangement of furniture and interior decoration, rounded lines and the way light is received and the very location of the hotel (all rooms overlooking the sea) show management environmental concern.

Thus, the first three floors represent the fire (red), the following two Earth (brown), floors 6 and 7 the water (sea green) and the last floor the air (white). All the hotel accommodations have the same principles of harmony, high standards and modern facilities.

Ecological Certified. Vega Hotel has shown interest in the direction of protecting the environment and ensures maximum safety conditions for customers and employees. Thus were created and implemented the requirements of the Eco-Hotel, becoming the first hotel in Romania certified by international certification body Eco-Hotel Management System. Eco-Hotel certificate granting has a guarantee that governs all the processes within the Vega Hotel. Eco-Hotel Management System certification was granted following a thorough and strict audit conducted by TUV Rheinland Portugal in cooperation with TUV Rheinland Romania. TUV Rheinland Group, optimizes, verifies and documents the safety and quality of worldwide products and systems, services and people.

Eco-Hotel is an exclusive standard that adds value to the hotel, being an additional guarantee of quality hotel services at European level. The new management system certified by TUV Rheinland that addresses hotel units is designed to reduce their impact on the environment.

Hotel Vega obtained from the audit, a very good score, in addition to satisfying the mandatory 90% of the additional requirements. The minimum requirements for certification Eco-Hotel consist of 100% in fulfilling the mandatory requirements and at least 50% of additional criteria. Score of Vega Hotel is very good, placing it on the Romanian seaside hotel unit in the top of the best European hotel units.

Joining the largest environmental rally ever held in the world "Earth Hour" lights closing for one hour per year in a given day, along with the rest of the planet, shows attention to the already fragile environment by hotel investors.

2.3. Saturn Hotel

Saturn 5 star classified hotel is the only hotel of this category in the Saturn resort and the first hotel in Romania to receive eco-label for tourist accommodation services, showing permanent care and concern for environmental protection.

Ecological Certified. It is the first hotel in Romania that has received from the Ministry of Environment and Sustainable Development (MESD) European Ecolabel for tourist accommodation services, the national eco-label Commission, the advisory body, with a role in evaluating the eligibility criteria. Thus, there have been examined the requirements for the label in accordance with the decision establishing criteria no. 287/2003/EC the European eco-label for tourist accommodation services and found that the requirements set out in the above decision are being met. From a total of 84 mandatory and optional criteria, the Saturn hotel has managed to meet all 37 mandatory requirements and another 21 optional.

The criteria focus on reducing consumption of electricity and water, reduced use of chemicals and selective waste collection. Gaining 30.5 points, almost double the minimum required (minimum score required to obtain eco label is 16.5 points) and the hotel was the eco-label shows that the services and try to protect the environment while showing managerial concern for quality.

Worldwide, more than half of the tourists choose for their destinations a hotel that respects the environment through its services.

It is to remark in this situation that tourists are increasingly interested in more ecological services offered, trying to find out what it means to be an "eco" tourist. Although the term 'eco' automatically leads to the idea of a diet based on organic products, without additives and preservatives, the hotel is focusing at least for now, largely just on providing environmental services, nutrition program, "bio" being present in the hotel offer only raw material suppliers, sorting food and supplies from its own organic fruit orchard.

Tourists are given cards that can help reduce electricity consumption. When they accommodate they are asked to reduce water consumption for washing teeth, etc.

The interiors are decorated in warm and soothing colors, colors that do not require additional electricity consumption.

Saturn Hotel has been designed from the beginning to save energy, with a sustainable investment of 3 million euros.

3. Hotel eco management – a sustainable development requirement

It can be concluded that to adopt a pro-environment hotel management capital is needed. Major hotel chains and management companies have substantial capital, thus have more opportunities both for better education and for strategic management. Smaller units operates with shorter time horizons and less strategic 'know-how'.

In order for the Romanian hotel owners to improve attitudes regarding environmental policies and strategies, the example of European hotels should be followed. Thus, the large European hotels use between 170 and 440 liters of water per day, depending on the source of information and, of course, the efficiency of hotel management. Solid waste, on average, can reach 1 kilogram per person per day in a classic hotel, while in efficient hotels this figure is reduced to just 50 grams. Besides these two examples, it is added knowledge gained in environmental practices, knowledge that differentiates hotel chains and affiliated units from independent hoteliers, but also eco-managed units with traditional management.

Hence the desirability and importance of a more environmentally responsible architectural design, renovation and operation of hotel properties is becoming necessary in the future with a broad vision, open to new eco-management challenges.

With a slight increase in expenditure (2-4%) for a green building project, aggregate savings fall to about 40% per annum, effective return of the investment can be done in the first 2-3 years.

A complete control system (BMS), lead to electricity savings of up to 40%.

Benefits from automation generalization in all types of buildings, including hotels are enormous. The Active Energy Management systems have systematic controllable and predictable reductions of consumption across all buildings, ensuring optimum comfort of tourists. Integrated solutions can cause constant decreases by 30% of electricity consumption and heat for long periods of time and significant reductions in personnel.

Punctual solutions put together three important elements: energy benchmarking, CO2 footprint clarify criteria (design, system active / passive high load, energy efficiency and low recovery of energy) and information / education of users in this case, tourists.

4. Conclusions

One explanation for the Romanian hotel owners that are not interested in organic certification would be that Romania, as a relatively new member of the European Union, still lacks a tradition of eco-label, as countries like Denmark or Italy. On the other hand, nor certification costs are negligible. High costs and the difficulty of qualifying for the European eco-label keep the certification off the Romanian hotel products and services.

Abstract

The capital market plays an important role in every modern economy, regarding both, its current state and its sustainable development. The aim of this paper is to present the main role of the capital market on all of the three levels on which they appear (the macroeconomic level, the microeconomic level and the individual level), using a comparative analysis between the European capital markets and the American ones, in order to highlight the necessity of their development. Also, the paper analyses the growing importance of the capital market in the process of financing the economy, which has become an important and essential part of any long term sustainable development strategy employed by any modern state.

Key words: capital market, sustainable development, systemic risk, modern economy.

J.E.L. classification: O42, E44, G11, G14.

1. Introduction

Taking into account the current evolutions of the capital markets and the general state of the economical and financial environment, we believe that an overview of the role of the capital market in the modern economies may prove to be useful for remembering their importance. The aim of this paper is to present in a non exhaustive manner the main characteristics of the capital markets and their importance for the modern economy,

using a review of the main ideas that appear in the academic literature so far. In order to achieve our goal we have organised the paper into four sections. Thus, section one provides an insight on the positive impact of the capital markets on the modern economy at three levels: macroeconomic, microeconomic and individual. The second section underlines the main risks associated with the capital markets while underling the role of the derivate products in a modern financial system. Then, in section three of the paper we underline the importance of the capital markets on the modern economy, using some empirical evidence based on data provided by the World Federation of Exchanges. The last section summarises the main ideas of this paper, underling the necessity of the capital markets development in a modern economy, like the European ones.

2. The role of the capital markets in the modern economy

A good functioning of the capital market represents an incontestable factor these days in order for the market economy to work. Regardless of the interpretations given to this subject, it is considered that in order for the market economy mechanism to work, the capital market must ensure the fulfilment of two main objectives: first, the financing of the economic activities and second, the insurance of the capital flows based on the economic efficiency principles and the diminishing of the default risks. Based on these principles and the effects that the *capital markets* are producing we can argue that they are representing *one of the main*

stepping stones on which the modern world relies, at least on its economical dimension.

The current stock exchanges have gone through a fundamental change over the last hundred years in order to achieve their current position, as the stepping stone of the modern economy, from their humble beginnings (the first stock exchange in the modern sense is considered the one founded in Anvers in 1531). The ultimate goal of this transformation is the creation of a stock exchange able to trade 24/7 globally. A good example of the magnitude of the transformation that these stock markets have gone through is the New York Stock Exchange, which became, after the merge with the pan-European stock exchange Euronext, the most important stock exchange in the world. In 1792, 24 small American investors, that used to meet under a sycamore in the south side of New York, have decided to put the basis of what it will become the largest stock exchange in the world. Two centuries latter the US Treasury Secretary, James Brady, declared that "the New York stock exchange has managed to handle the most astonishing transformation in the financial world, evolving from transaction settling under a sycamore to electronic transaction, thus becoming a model for the global financial industry" (Dominique Gallois, 1997, p. 14). Currently, the New York Stock Exchange - became in the meantime through an intercontinental merge NYSE Euronext - is characterised by a high degree of capitalisation, the specialisation of its intermediaries, fast order execution and a high degree of fluidity and liquidity.

These transformations have been enhanced especially by the emergence of the trading technologies and informational communication methods that have enabled development of new financial services and products and have lead to the current state of evolution where classical trading methods are combining with high tech informational technologies. The modern stock exchanges are ideal institutions for commercial transactions in large volumes that are handled in a very fast meaner (Dornescu, 2001).

Thus, from a place that was considered "taboo" for the inexperienced, not so long ago, the capital market has become a place that attracts more investors every day, both private and institutional, and its role in the

economy is becoming central.

The role of the capital markets in the modern economy can be identified at different levels: at the macroeconomic level, at the microeconomic level and at the individual level.

Figure 1 - The levels at which the capital markets have a direct impact on the economy

Source: based on Stoica, 2002

At the macroeconomic level the capital markets manifest its fundamental role, that of financing the economy. Through this fundamental role, the capital markets manage to *provide an efficient capital transfer between the entities that are registering an excess of liquidity to the ones that are registering a deficit of liquidity and which manage to provide this capital with a higher usage value into the economy* (Stoica, 2002). The primary market provides the necessary settings for the initial public offers to be lunched, both for stock and bonds, which provides the necessary financial resources for the agents present on the market. The fundamental role of the capital market is more visible through the secondary market which provides access to the public and allows the titles that have been already emitted to be freely traded and thus allowing the function of the financing mechanism for the economy. In this context, we can identify the interdependence between the two components of the stock market: the primary market provides the economy with the necessary funds in order for it to evolve and prosper and in order for this segment to be believable and attractive to investors, the secondary markets needs to provide the investors with the realistic opportunity to clear their positions and sell their titles at a fare value price, almost instant at any time. This represents the mechanism that allows the transfer of funds from the economic agents that are registering an excess to the agents that are registering a deficit.

To underline this important role of the capital market we can *compare* this form of economic financing with the alternative that exist and especially *with the banking sector alternative*. If in the European Union the economy is mainly financed through the banking sector, in the United States the capital market represents the main source for financing the economy. In 2009 for example, in the United States approximately 70% of the economy was financed through the capital market, while only 30% of it was assured through the banking system (FED, 2010). By contrast, in Europe, approximately 60% of the economy was financed through the banking system (BCE, 2009). The banking system is limited in its financing offer by the fact that it relies heavily on the liquidities attracted from the population and other economic agents. On the other hand the excessive financing of the economy through banking credits can generate high systemic risks. A relevant example in this sense is the Asian crisis, with its painful lessons, that serves to underscore the importance of capital markets, because the crisis revealed major weaknesses in the region's financial markets, in particular, an excessive reliance on the banking sector (Krugman, 2009). From these aspects, we can underline an important characteristic of the capital markets, which permit the financing of the economy without the danger of creating inflation bubbles, because it allow the activation of the "passive currency", held by the excess liquidity agents, and its usage in the real economy for the benefit of the whole society.

Also at the macroeconomic level, *the capital markets provide the necessary mobility of capitals among the different economic sectors*, from the more inefficient ones to the more efficient ones, enhancing the overall strength of the economy. By allowing such a dynamic, the capital market provides an investor with the possibility to invest in high innovative and high efficient sectors of the economy and the possibility of immediate reallocation of capital at the moment when new domains are taking off. Accordingly it allows a higher profitability.

Another interesting facility that the capital market is providing is represented by *the intermediation of mergers and acquisitions*, both at national and international level,

which have become more interesting in the last period, especially as a result of the financial turmoil and the necessary consolidation process that has followed. These types of operations are carried through the capital market using the so called "tender offers".

Because of the important role of the capital markets and implicitly of the stock market as one of their main components, their development represents an etalon of a modern and successful economy (Szel, 2005).

The stock exchanges picture also the image of the economical, political and social events that are occurring not only at the national but also at the international level, *reflecting like a mirror the real state of the economy*. Because of this, it is justified to believe that the stock exchange cannot represent in the medium and long term a feasible alternative to the real economy. If the real economy has a direct impact on the stock market, then also the reciprocal is true: the financial fluxes that form the secondary markets are useful clues for the economy and determine shifts in the investments that are about to be made in the real economy, determining investors to reconsider their options and allowing overall a better allocations of financial funds in the economy.

Even taking these realities into consideration, we must not forget that the stock market represents only an indicator of the real economy. For example the Eurostat uses 35 economical indicators in its analysis regarding the state of the European Union economy and only one of these describes the evolution of the stock markets.

But, not every drop in the value of the stock market represents a sign for an upcoming financial crisis. If these drops are not followed by inflation, a drop in the production or any other economic setbacks then they only represent price corrections through which overpriced stocks are adjusted to their real value. Moreover, we must take into account the fact that the activity of every stock market is sensible to rumours or any other type of news related to it, which sometimes tend to be followed by herd mentality actions, especially from the part of individual investors, and thus provide a very good environment for panic attacks.

The impact of the stock exchange is tremendous on the real economy, especially in the more advanced economies where economic agents are used to follow the information fluxes of the capital market in order to determine the future evolution of the economy. Moreover a crisis of the capital market can extend itself to the real economy, and even spread at an international level, like in the case of the financial crisis that started in 2007 in the United States and which has spread all around the world.

At the microeconomic level the stock market has an impact on the economy through the multiple benefits that it is providing to the listed firms.

We must acknowledge the fact that the benefits of listed firms have been increased mainly as a result of the stiffening of the banking credit process, in which banks required extra guaranties to firms that wanted to receive additional banking loans, making it more difficult to them to obtain new capitals for their projects. In this context, the necessity for firms to maintain an adequate financial structure in order to be able to finance their fix capital assets has become more important in time (Pop, 2003, p. 202).

The listing of a firm on the stock market provides a necessary diversification of financing options. So, the firm gains in economic flexibility and financial independence, being able to finance more easily its development through capital expansions or through the issue of attractive financial products, like bonds that have the option to be turned into stocks or preferential stocks.

The listing of a firm enables it to access *different sources of financing* in the future through the capital market and thus the capital market is providing the necessary resources for its future development.

Another advantage that is generated for the listed firms through the stock market is *free publicity*. Information regarding the transactions that have been registered in one day at the stock market are widely disseminated in the printed media, radio and television, and contain, beside the transactions summary, the names of the firms listed at that stock exchange. The reputation that the firms listed at the stock exchange have can determine a raise in their share of

the market and thus enabling them to gain an important advantage on their competitors.

The mechanism of the stock exchange permits *the determination of a firm's daily value* through its stock market capitalisation. The report between offer and demand for a certain firm's titles establish that titles daily value, which fluctuates and can penalise certain managerial decisions that are not in accordance with the fundamental objective of any economical endeavour: the efficient usage of limited resources in order to gain a higher profit.

At the individual level, the stock exchange allows investors to place their resources at any time in what they believe to be the most efficient financial titles that are traded, while also providing the opportunity to transform almost at an instant these titles in liquidity, both operations taking place in an organised environment and at a reasonable fair price. The investors are provided by the issuers with continuously and real information regarding the financial results that they have obtain and also in regard to any factors that may lead to a price shift of their title. The shareholders are protected against any malicious actions that may occur on the stock market, their rights being protected and underlined in the status of the stock exchange.

3. The risks associated with the capital markets

As we have presented, the capital market has a determined role on all three levels of an economy but we must not underestimate the risks associated with it.

Influenced by some reports in the media, a part of the general public tends to consider the capital market as a "*zero-sum game*", where the gains of one investor represent the lost of another. Moreover, there is some concern that the stock exchange may represent a source for economic instability, the volatility of the exchange being enhance by the development of derivates products and their transaction (like the CDS or the CDO). The critics, especially taking into account the recent financial downturn, argue that the development of such products *has introduced and enhanced the systemic risk* that the stock markets are generating (Obstfeld and Taylor,

2004, Duffie, 2007, Blanchard, 2009). The reality has instead provided some different arguments regarding this aspect, underling the impact that these financial products had on the diminishing of transactional risks. Many of the so called derivate financial products are truly innovative providing benefits for all the market participants. Overall the benefits of derivate products are more than evident, while their negative aspects have been very little documented, tending to occur especially when these financial instruments have been used in a malicious way, while being insufficiently supervised and regulated.

The internationalisation of the national financial markets in general, and that of the capital market in particular, has lead to the enhancement of the identity losing risk for the listed firms. Thus, the stock market has become the battleground for some violent encounters between firms that have different financial strengths (e.g. Vodafone AirTouch bid for Mannesmann AG).

Despite all the aspects presented above, *we consider the advantages that the capital markets mechanism is generating for the whole economy are more important than the associated risks that exist.* The stock exchanges dissipate risks, enhance capital gains, direct information in the way it is best used and keep managers competent. *The prosperity of a modern economy depends on its ability to foster an efficient capital market.* Thus the capital market provides the capital necessary for the development of the economy, satisfying the interests of investors who seek security and flexibility and of firms who want access to a flexible and easy to reach source of financing.

Taking into account the current economical and financial environment, many governmental agencies and commissions have been created in order to better regulate and supervise the different financial markets that exist in the modern economy. The aim of the regulatory process is to provide the safety of the transactions and that of the participants, ensuring and guarantying the existence of the counterparts and also to standardised procedures. Also, the regulation of capital markets aims at protecting the investors – especially the individual ones, at allowing an efficient and fluent functioning of the markets, at diminishing the effects on

the real economy in case of a negative evolution of these markets and not the least at imposing fair and attractive practices that are mutual beneficial for all participants (Kawai and Pomerleano, 2010). Thus, the regulation of the capital market is carried out at national level (and in some circumstances at international level, like in the case of the European Union), according to the legislation in place, by a governmental appointed institution (e.g. based on these characteristics, the capital markets is regulated in the United Kingdom by the Securities and Investment Board (SIB) or in France by the Commission des Operations de Bourse).

4. The importance of the capital markets in the modern economy

The importance of capital markets in the financing mechanism of the modern economies has grown in time, as the economic activities have evolved and diversified and the saving degree has risen. These evolutions have allowed the capital markets to become an essential and alternative mean for financing firms and public entities alongside the banking sector, with which it's competing for market share. Moreover, the single usage of the banking sector as a sole provider of capital for the economy can lead to disruptive effects on the stability of the currency.

The financing mechanism through the capital market has become such an important way for the modern economy to obtain its financing resources also because the capital markets are providing *a financing source for the economy that is non-monetary, non inflationist and which aims at benefiting all the participants to the transactions:* the title issuers, the buyers, the non-monetary financial intermediaries and also the stock exchanges.

The importance that the capital markets (and also its size) have in an economy can be measured through a series of quantitative indicators, from which the most important are *the turnover* and *the stock market capitalisation*.

In the current conditions in which the different stock markets from around the world are interconnected, influencing each

other, we founded it relevant to provide the following table which presents the capitalisation of the main stock exchanges in the world. We argue that as an aftermath of the financial crises that started in 2007, the capitalisation of the main stock exchanges in the world at the end of 2008 has dropped from the previous year, while at the end of 2009 an upward trend is present on all the major stock exchanges of the world.

Table 1 – The level of capitalisation of the main stock exchanges, between 2007 and 2009, (in millions USD, yearly variation)

Stock Exchange	2009	2008	2007	Variation 2009/2008	Variation 2008/2007
NORTH AMERICA					
NYSE-US	11.837.793	9.208.934	15.650.832	+ 28,5%	- 41,2%
NASDAQ	3.239.492	2.396.344	4.013.650	+ 35,2%	- 40,3%
EUROPE

Note: OMX has been acquired by NASDAQ in February 2008, Borsa Italiana has been acquired by LSE in October 2007 and Euronext has merged with NYSE Group in April 2007.

Source: Own calculation based on data provided by World Federation of Exchanges

We can observe that the capital markets are playing a defining role in the economy of the United States of America, a good proof in this sense being the fact that the largest stock exchange in the world operates in New York – the New York Stock Exchange. Another aspect that can be observed from the up table is the fact that in 2008 all the main stock exchanges from north America and Asia have registered drops in their capitalisation: NYSE falling by 41,2%, NASDAQ by 40,3% and Tokyo SE by 28%, while the backlash of the financial crisis has been also felt in Europe where the main stock exchanges have also dropped by: 47,2% in the case of the Deutsche Börse, 54,7% in the case of OMX and by 50,2% in the case of Euronext.

Following the massive rescued planes put in motion by public authorities all over the world the stock exchanges have registered a raise in their capitalisation in 2009, but still remaining under their 2007 level.

These evolutions that characterise the main stock exchanges are also present on the medium and small stock exchanges of the world. Thus, according to the statistics of the *World Federation of Exchanges* which follows the actives of 53 stock exchanges, during 2008, the year in which the effects of the global financial turmoil were the most hard felt, the global capitalisation of the 53 stock exchanges was of 32.551.432,8 millions USD, being 46,5% smaller than the one of the previous year (when the global capitalisation of the 53 stock exchanges was 60.854.944,5 millions USD). The revival of the activities that characterised the most advanced stock exchanges in the world was in fact a global trend, which is underlined by the evolution of the global capitalisation of the 53 stock exchanges that are monitored by the World Federation of Exchanges which roused by 20,1% in 2009, when compared with the previous year.

Beside the two main indicators of the capital markets development that we have mentioned, the global turnover and the capitalisation, in order to underline the importance of the stock market in an economy we can also use an alternative indicator, represented by *the ratio between the capitalisation of a stock market and its national GDP*.

Table 2 – The evolution of the ratio between the capitalisation of the main stock markets and their national GDP, between 2004 and 2009 (percentage)

Stock Exchange	2004	2005	2006	2007	2008	2009
NYSE	108,3	109,2	116,4	113,3	64,8	83,4
Tokyo SE	73,3	107,4	108,3	98,8	64,0	65,8
Euronext	70,7	86,4	101,0	104,3	59,7	68,2
Deutsche Börse	39,7	46,1	53,8	63,4	30,4	34,7
LSE	127,4	145,0	149,2	138,9	66,0	93,5

Source: Own calculation based on data provided by World Federation of Exchanges

We can observe that the ratio of the capitalisation of the stock exchanges from our panel in the national GDP has grown steadily between 2004 and 2006, underling

their raising importance in their respective economies. As the financial turmoil has grown we observe an abrupt drop in this ratio for all the stock exchanges in our panel which starts in 2007 and intensified itself in 2008. As noted earlier, as a backlash to the massive stimulus packages put in place all over the world by the national governments, the ratio between the capitalisation of the main stock markets and their national GDP has registered a small rise at the end of 2009.

We can observe that this ratio is registering a different value for the stock exchanges from our panel, with the New York Stock Exchange scoring the highest on the list, and thus underling once more the determinant role that it plays in the financing process of the US economy. The lower levels of this ratio, that characterise the European stock markets, can be attributed to the fact that these economies tend to be financed through the banking sector, as we have noted earlier. Nevertheless the importance of the capital markets in Europe was amplified by the introduction of the single European currency, at least in the euro zone economies, starting with 2000, according to data provided by the Federation of European Stock Exchanges.

5. Conclusions

As we can observe from our paper, in a modern economy, capital markets are an important and efficient conduit to channel and mobilise funds to enterprises, and provide an effective source of investment in the economies they serve. They play a critical role in mobilising savings for investment in productive assets, with a view to enhancing a country's long term growth prospects, and thus act as a major catalyst in transforming the economy into a more efficient, innovative and competitive marketplace. In addition to resource allocation, capital markets also provide a medium for risk management by allowing the diversification of risk in the economy. Also, a well-functioning capital market tends to improve information quality as it plays a major role in encouraging the adoption of stronger corporate governance principles, thus supporting a trading environment which is founded on integrity. Despite the many benefits of the capital markets, we must not exclude the risks

associated with it, for example the systemic risk that can be generated in some cases on these markets, as the recent financial crises shows us. Thus, the regulatory and supervision entities that are responsible for the capital markets must developed and implement regulations and procedures which can handle the ever changing financial environment. Overall, capital markets provide a helpful environment for the financing of a modern economy as long as proper regulations and supervisions entities and procedures are in place.

Abstract

In the last decades, financial innovation has been in the fore front of all the major changes which have affected the financial system, both at national and international level. Thus, the research of this subject has become a major field of research, its importance growing since the start of the current financial and economic crisis. In this context, the aim of this paper is to underline the impact of financial innovation on the stability and efficiency of the financial system while also taking into account the implications over the systemic stability of an economy. The results of our study highlight the need for a cautionary approach regarding the usage of financial innovations, as new financial instruments used excessively or in an inappropriate manner, without proper regulations and supervision, can lead to financial instability and the accumulation of major systemic risks.

Key words: financial innovation, financial stability, efficiency, crisis, systemic risk

J.E.L. classification: G01, G14, G32.

1. Introduction

Taking into consideration that, over the last decades, financial innovation has been considered to be one of the major causes of the radical changes that took place in the financial systems, both at the national and international level, its analysis represents an actual and interesting problem for both policy makers and participants from various financial markets, whether we are talking

about investors, financial intermediaries or end-users of financial services. Within this framework, it becomes clear that a better understanding of *the impact of financial innovation on the two key components of the financial sector, namely: stability and efficiency* is crucial in order to ensure that episodes such as the current financial crisis does not happen again.

In this context, *the purpose* of this paper is represented by the study of the financial innovation and of its implications on the financial systems development, highlighting both the positive and negative effects that the financial innovation has on its efficiency and stability. Thus, taking into consideration that all financial innovations encompass advantages as well as risks, *the core question* that arises refers to under what circumstances financial innovations enhance the efficiency and the stability of financial systems, and, under what circumstances do they threaten their stability?

In order to achieve this purpose the research is structured in *five parts*: *the first part* contains introduction remarks regarding the field of research and the importance of the approached theme; *the second part* is dedicated to a literature review which identifies the main researches undertaken so far on this subject; *the third part* highlights the key role played by financial innovation in increasing the efficiency and the stability of the financial systems, and *the fourth part* of the paper reflects, mainly, the negative impact that the financial innovation may have, in certain circumstances, on the stability of the financial systems; while *part five* provides the concluding remarks of the research.

The *methodological approach* used starts with a literature review, which is useful because, on one side, it helped us to familiarise with the main studies from this field and, on the other hand, we were able to underline the way in which our research will cover the least approached areas of this field, especially the problems regarding the trade-off which often exists between the efficiency and stability characteristics of the financial system. As a method of data analysis we have used systematisation techniques and also a series of comparative tables and graphics. In order to obtain our data, we have used mediate techniques for data gathering, like official statistics of the Bank for International Settlements (BIS), different reports, studies and researches.

2. Financial innovation – a literature review

In general, most scientific papers undertaken on the subject represented by financial innovation have focused on three main research areas: the concept of financial innovation, the drivers of financial innovation and the effects of financial innovation.

Regarding *the concept of "financial innovation"*, taking into consideration its' dynamic and complexity, even after a quarter of century, the academic literature has not reached a consensus. Anyway, one of the most widely and frequently used definition is that offered by Frame and White (2004, p. 118), which after having analyzed the basic functions of the financial system, considered financial innovation as "something new that reduces costs, reduces risks, or provides an improved product/service/instrument that better satisfies participants' demands".

Concerning *the drivers of financial innovation* there are four main theories: the circumvention innovation theory (Kane, 1981), the transaction regulation innovation theory (Sylla, 1982), the cost innovation theory (Niehans, 1983) and the constraint-induced financial innovation theory (Silber, 1983), each of these theories explaining in a comprehensive manner the reasons why the pace of financial innovation have accelerated in recent decades.

In respect to *the effects of this process*, it is considered that financial innovation has a direct effect on reducing the negative elements (such as costs and risks) as well as on increasing the positive ones (through development of products, services or instruments that would better meet market's needs). Hence, Van Horne (1985) highlights in his paper that a real financial innovation helps to increase market efficiency and completes the range of products and services. Also, Llewellyn (1992) argues that financial innovation refers to the creation of new financial instruments, techniques and markets as well as to the separation of different characteristics and risks of individual financial instruments, followed by their combination in various new ways. The author emphasizes also that the financial innovation helps to increase the overall efficiency of the financial system. However, in the aftermath of the 2007 crisis, a series of studies have underlined also that, in certain conditions, the impact of financial innovation for stability is ambiguous and that techniques and instruments, used to shift credit risk in a stable environment, may become problematic when the market environment becomes more volatile and uncertain, and when there are systemic shocks (Anderloni et al, 2009).

Summarizing, *the researches undertaken so far regarding the subject of financial innovation are still in an early stage*, when compared with the abundance of researches undertaken on the innovation from other sectors of the economy (like the industrial innovation), and we can observe also a lack of systematic empirical researches with unique and unanimously accepted results. Thus, we consider that *this research can represent a relevant response to this very important subject, that should be studied continuously in order to improve its comprehension for the benefit of those who produce it, use it and eventually who regulate it.*

3. Financial innovation – key factor for the development of financial systems

The process of financial innovation is one of the key factors for the development of financial systems because it contributes to the achievement of five basic functions of a

financial system: (1) it increases the variety of the financial spectrum by combining the characteristics of various financial instruments in order for the advantages of one instrument to alleviate the disadvantages of another; (2) it enables various types of risk to be more efficiently managed and shifted to those who have a greater ability and willingness to absorb risk; (3) it increases the liquidity of assets and markets; (4) it allocates funds to their most efficient use and (5) it may give investors access to new markets from which they were previously excluded. Based on these functions we consider that the *various forms of financial innovation* can be grouped as in Table no. 1.

Table 1 – The taxonomy of financial innovation

Types of financial innovation	Examples
• Instruments/processes that ensure the transfer of price risk	Swaps, forward, futures and options contracts
• Instruments/processes that ensure the transfer of credit risk	Securitisation, collateralized debt obligations - CDOs, credit default swaps - CDSs
• Instruments/processes that allow the growth and development of firms and corporations	Bonds
• Instruments/processes that contribute to the liquidity enhancement	Securitisation, Direct access trading (DAT)
• Instruments/processes that ensure the financial services modernisation	ATMs, internet banking, Target 2 Securities
• Instruments/processes that ensure the substitutability between different financial instruments	Debt equity swaps

Source: realised by the author

The scientific studies from the academic literature regarding *the effects, both positive and negative, generated by the different types of financial innovation on the stability and efficiency of the financial systems* are varied. Thus, on the one hand, there are a series of studies that highlight *how financial innovation help to increase the efficiency and stability of financial systems*. In this respect, Greenspan (2004, p. 4) argued that: “credit derivatives

and other complex financial instruments have contributed to the development of a far more flexible, efficient and hence resilient financial system”.

In general, the main benefits of the financial innovation (although not the only ones) regarding the increase of the financial sectors efficiency are related to *the possibility of innovative instruments to reduce the financial intermediation costs* (basically this can be achieved in two ways, either by facilitating borrowers the access to a wider range of financial markets which are providing additional lending facilities, or, in some cases, by creating the necessary conditions so that the financial institutions would be able to obtain scale economies which will reduce the costs of the services that they provide), *to enhance the liquidity* (e.g. CDOs enable banks to create liquidity based on their loans, which traditionally represent an illiquid component of their portfolio) *and, most important, to enable risks to be dispersed optimally throughout the financial system* (for instance, a bank could maintain a relationship with a client over an extended period of time without incurring an excessive credit-risk exposure to the customer, in this respect, credit derivatives providing an attractive mechanism for managing risk exposure).

However, we must take into account that one of the financial systems characteristics is represented by the trade-off which often exists between its efficiency and stability (more precisely, the impossibility to obtain them both at the same time). Extrapolating this situation, some analysts considered that this is true also in the case of financial innovation, particularly with respect to credit derivatives. In this context, *the impact of financial innovation on the financial system stability represents a controversial issue*. Thus, on the one side, because the financial innovation enables risks to be dispersed optimally throughout the financial system, it increases its stability, but, on the other side, because, in certain conditions, it allows the accumulation and proliferation of risks, it can have a deleterious impact on the financial system stability.

Hence, there are a number of *ways through which financial innovation can enhance financial system stability*, giving it a higher resistance to shocks:

- innovative instruments spread risks more widely within the financial system, in this way the risks being absorbed by those who are more willing and more able to deal with them, thus emphasizing the stabilizing role of financial innovation.
- in many respects, this type of instruments enable banks to respond more easily to certain types of shocks. Greenspan suggested that “[the stability that has characterized the financial systems until 2007] suggest a marked increase over the two or three decades in the ability of modern economies to absorb unanticipated shocks...this has doubtless been materially assisted by the recent financial innovations that have afforded lenders the opportunity to become considerably more diversified and borrowers to become far less dependent on specific institutions or markets for funds” (Greenspan, 2002, p. 6).
- another dimension to these issues is provided by the Bank for International Settlements, which considers that “The ability to switch smoothly between balance sheet financing and market-based financing contributes to the robustness of a financial system and improves its ability to deal with strain” (Knight, 2004, p. 6).

In conclusion, we can state that *the benefits driven from the development and use of financial innovations are manifold*. Hence, the cost of financial intermediation may be reduced due to the use of financial innovations, offering the entities which seek financing the possibility to enter different markets and allowing different actors from these markets to effectively exploit their competitive advantages. Also, new instruments enable arbitrage between markets in different countries, which lead to the decrease of pricing anomalies, and implicitly to the reduction of market imperfections. Moreover, a number of financial instruments allows the use of diverse hedging options enabling the increase of protection vis-à-vis risk, while another series of innovative financial instruments facilitate the risk assessment, transferring it to those entities that are more capable to manage it efficiently. Nevertheless, these instruments enable different risks to be divided and then separately priced and “sold”. Thus, we can

assert that if these processes are carried out in a correct and professional way, then these innovative financial instruments will have a direct effect of increasing the efficiency of resources’ allocation in the economy.

4. Controversies regarding the effects of financial innovation on the stability of financial systems

The manifestation of the financial crisis which started in 2007 highlighted the existence of a high number of opaque financial products in the international markets, such as: credit default swaps, mortgage-backed securities or collateralized debt obligations. The role that these financial products have had within the financial crisis has triggered a heated debate regarding the value that they bring to the international financial system as well as regarding which would be the correct response from the authorities in charge with the regulation and supervision of these innovative instruments. It is already obvious that from the debate around this subject have emerged two streams of opinion, on the one hand, are those who believe that financial innovation is largely unnecessary (e.g. Krugman (2008): „It's hard to think of any major recent financial innovations that actually aided society, as opposed to being new, improved ways to blow bubbles, evade regulations and implement de facto Ponzi schemes”) and on the other hand are those who believe that financial innovation has both positive and negative parts (e.g. Levine (2010): „Even if the last few years demonstrate that financial innovations can be used as tools of economic destruction, the last few centuries demonstrate that financial innovation is crucial, indeed indispensable, for sustained economic growth and prosperity”).

Thus, there is the possibility that the financial instruments that should increase efficiency, instead, in certain circumstances, may threaten the financial stability. These instruments can as well increase or reduce financial stability, enabling these fluctuations to put into question the overall financial innovation capacity to generate financial stability. For instance, the credit derivatives (one of the most invoked examples of financial innovation over the last years), allow

the banks to improve their image, similar to the process of "window dressing", but this arrangement could hide the reality (Stoica, 2010).

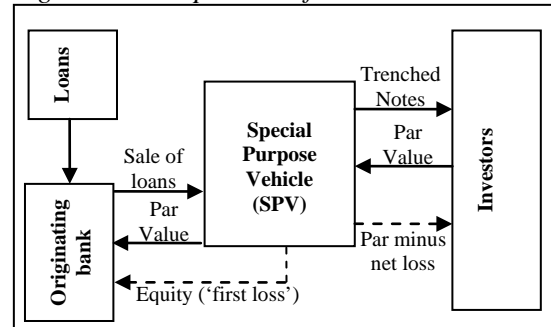

These considerations lead to a preliminary conclusion related to the implications of financial innovation on the stability of a modern financial system. It would seem that *the financial instruments that allow better dispersion of risk and that emphasize the role of markets in financial systems are also reducing the vulnerability of the financial systems to small shocks*, allowing a more effective management of these events. Hence, the capacity of financial systems to stabilize is enhanced by the financial innovation. On the other hand, *the financial innovation can lead to the exposure of financial systems to major and systemic shocks*, enabling the management of this type of shocks to be more difficult. An example in this respect may be represented by the systemic liquidity shock, generated by the decrease of the liquidity from the global financial markets, experienced in 2007. Thus, Rajan (2005, p. 16), for instance, concludes that: "[while] the financial system is more stable most of the time, we may also have the possibility of excessive instability in really bad times (as well as higher probability of such tail events)".

Thus, despite the fact that the derivative products have been created to help dissipate the credit risk of the issuers, they hide a number of risks that have facilitated the emergence and expansion of the financial crisis. This was due to, on the one hand, the lack of transparency and the extremely high complexity of these financial instruments, and, on the other hand, the fact that many of the financial entities involved in the transactions with such type of financial instruments didn't fully understood the risks associated with these transactions.

Basically, we can state that there was a tendency of proliferation of derivative instruments with a high degree of complexity and opacity, as well as of trading such instruments through certain financial entities equally opaque, such as the so-called Structured Investment Vehicles (SIV) (see Figure no 1). Thus, in a typical securitisation transaction where banks transfer the legal rights of the assets to an SPV, CDOs involve the transfer of a portfolio of loans

(collateralised loan obligation: CLO) or bonds (collateralised bond obligation: CBO) or a mixture of the two (CDO), and the tranching of the risk to attract investors. The use of tranching techniques enables the creation of highly structured types of credit risk profiles (Anderloni et al, 2009, p. 254).

Figure 1 – The process of cash securitisation

Source: Mengle (2007)

Chart no. 1 highlights the proliferation of financial derivatives at the global level, the total value of the swap contracts on the interest rate and of the other types of derivatives reaching in 2008 the amount of 672 trillion dollars, equivalent to 11 times the global GDP, according to the estimations made by the Bank for International Settlements (2010). Just ten years previous, in 1998, the value of these financial derivatives was only 75 trillion dollars, equivalent to 2 ½ times the global GDP. Thus, the global derivatives market has simply exploded in the period 2007-2008, registering an annual increase of about 50%.

Chart 1 – The evolution of the total value of various types of financial derivatives issued in the period 1998 - 2010 at the global level (biannual values, trillion U.S.A. dollars)

Source: realised by the author based on the data provided by BIS

The British Financial Services Authority argued that the manner in which financial intermediaries have used the associated

financial entities, such as the SIVs, represented the main cause of the financial markets negative developments from the end of 2007. During that period, the liquidity of the securities market has mostly disappeared, after a period of several years during which there were significant increases in this market. The lack of liquidity has created major problems especially to certain types of financial derivatives, such as: collateralized debt obligations - CDOs or collateralized loan obligations – CLOs. In general, all the financial markets that have allowed the trading of such financial instruments have been hit hard by the financial crisis.

Despite the issues presented and the fact that the current financial crisis has seriously affected the international financial system, the opinion of the economists and government representatives present at the G20 meetings in 2009 and 2010 was that the financial markets will continue to be interconnected and with a strong tendency of globalization, while the financial innovation will continue to play a key role in the process of economic development (G20, 2009, p. 5). This vision is not only declarative, because the majority of the legislative changes made during this period within the G20 economies in order re-regulate the financial sector were taking into account these considerations. In this context, the president of the Financial Stability Council, Mario Draghi, stressed that regulations should not inhibit financial innovation, because it represents on the one hand the element that its needed in order provide to consumers diversified solutions of financing and on the other hand it's the element through which the lending process can be extended (Tonveronachi, 2010, p. 131).

Thus, we consider that the objectives of the re-regulation process should be represented by the strengthening of the financial system, without affecting the process of markets self-regulation and the process of financial innovation, because they represent some of the main advantages offered by this sector.

Also, we can say that ***the fragility of the financial systems is not given by the widespread use of innovative financial products, but rather by the excesses of the financial markets,*** excesses that the regulations in force and the existing

supervisory systems were not able or did not wanted to inhibit at the right time. Thus, we can consider that the current international financial system is based on correct and solid principles, which make unnecessary its entire redesigning and rather requires a readjustment of the supervision and regulatory framework in order for it to be able to cover the issues highlighted by the financial crisis, thereby increasing the stability of the entire international financial system.

5. Conclusions

The process of financial innovation is influencing directly two key components of the financial sector, namely: its stability and efficiency. If regarding the positive impact that the financial innovation has on the financial system efficiency there is a general consensus, regarding the financial innovation implications on the stability of the financial system, two visions have been crystallized. One of them argues that because the financial innovation enables risks to be dispersed optimally throughout the financial system, it increases the financial system stability. In contrast with this vision, the other view highlights that, because, in certain conditions, it also allows the accumulation and proliferation of risks, the financial innovation can have a deleterious impact on the financial system stability. A possible theory concerning the dual effect of financial innovation takes into account the nature of shocks, starting from the idea that on the one hand, in the case when minor shocks are manifesting, that are less correlated, the use of for example derivative instruments (with particular reference to those who spread risk) may increase the stability of the financial system and on the other hand, in the case when large systemic shocks are manifesting, accompanied by a reduction of the liquidity at the international level (as was the case in the summer of 2007), their use may increase the vulnerability of the financial system.

Under these conditions, *there is a need for caution, because the use of some new financial instruments on a larger scale or on a different background compared with the original one, without proper regulation and supervision, could generate instability.* Thus, the ideal policy approach is in our opinion to

find an appropriate balance between preserving safety and soundness of the system and allowing financial authorities and markets to perform their intended functions, by ensuring, firstly, that the necessary market-framing is in place and, secondly, by establishing a proper method for reviewing financial innovations.

Knowledge - An Essential Element of Labour Development in the New Economy

Șerban Andreea Claudia
Academy of Economic Studies, Bucharest
Andre_serban@yahoo.com

Abstract

Starting from the place and role of work, of social action in general we investigated their changing in contemporary society and especially in the New Economy. Starting from the changing of the society and moving to the changing to the economy, we designed our approach in a deductive way. We also sought to outline the changes in contemporary society, often characterized by the term Knowledge Society and, especially, in the economy having as background the industrial civilization and capitalist economic system.

Key words: Knowledge, Knowledge Economy, New Economy, labour

J.E.L. classification: D83, O15, J01

The complexity of modern economic environment has led some authors to advocate a new approach to the economy - based on a dynamically adaptive system. These economists argue that economies are also following the same basic laws of biological systems. These laws will manifest differently in economics and biology, but if we can improve their level of understanding, then we have the opportunity to get closer to the workings of markets and firms. The difference between the approach of the equilibrium in classical economics and in the New Economy is very suggestive presented by Ilya Prigogine: "Classical economics focuses on stability and balance. Today we observe the existence of instability, the fluctuations and evolutionary trends that occur at virtually all levels. We are facing a universe far more complex and more structured than we could ever imagine".

In this study we have taken as a reference the New Economy and/or global information economy, as the core of the Knowledge Society. We considered that such a society can not be build without a sustained creative effort. The world is changing rapidly and the economic, social and technical developments influence the life and action way. Globalization, technical and technological revolutions in the contemporary economy becomes what is called "Knowledge Economy", where new ways of organizing and governing the business work, requiring accelerated development skills, solid knowledge and a growing responsibility. Contemporary society becomes a society that teaches and that adapts to the new, and in this context, educational systems should seek the training of capable people who can develop their own skills in order to fully integrate into socio-cultural context in which they live.

The most comprehensive definition of the New Economy was developed by the World Bank and the Romanian Academy in the "Position Paper", presented at the 2002 World Bank Conference in Paris. According to this the *New Economy* is defined as *Knowledge-Based Economy* and have as important elements: producing knowledge through continuous innovation, knowledge dissemination to all members of society, intensive use of knowledge in all areas (and especially in technology and organization of human activities), education for this type of economy through education and training system based on innovation and research, the emergence of internationalized and dynamic markets.

Traditional economy is characterized by balance and stability, focusing on the use of traditional factors of production and comparative advantage having as main objectives economic growth, balance and stability, full employment and price stability. **New Economy** is seen as a complex,

dynamic and adaptive system, based on new inputs. New Economy uses e-commerce and other modern tools of e-development. It emphasizes on competitive advantage, multifunctional team, it has as favorite topics imbalance, instability, fluctuations, chaos, assuming the merger of the following phenomena: technological revolution (and rapid technological progress, particularly in regard to new information and communication technologies) and accelerating process of globalization (internationalization of part of the global economy and international financial environment changes).

New business models are based on the new world economic structure, new types of interaction and new technology in a global economic environment characterized by electronic commerce. In *pre-industrial society*, the workforce was employed primarily in the extractive industries and in areas close to nature. In contrast, *industrial society* is characterized by the dominance of the secondary sector, the workforce is employed in manufacturing industries, construction, transport, etc.

Industrial society gives way to the new economy, which is not industrial, but a postmodern economy, capitalist, postindustrial and informational. George Soros noted: "no system is perfect, so that neither capitalism nor communism are not perfect systems. Humanity is now trying to extract and preserve as many positive elements from each of the two systems".

The purpose of this economy will remain the human and his satisfaction of needs. If the human is out of the economy, it has no sense.

As Robert B. Reich considers an organization most important assets "are ingenious and talented people and not the property that can be bought or sold". Even if the past achievements have resulted in goods that could be sold (patents, copyrights, trademarks) and who "may claim a legal right of ownership", their future ideas can not be taken out of possession or sold.

Society as a whole is facing large challenges in terms of changing employment and work organization. New Economy is characterized by increased incorporation of knowledge into new products and services, increasing the importance of learning and

innovation, globalization and sustainable development.

The advance to the information society - knowledge based - is regarded worldwide as a necessary development to ensure sustainable development in the context of the "New Economy", which is based mainly on product and intellectual-intensive activities. Information society based on knowledge is more than the progress of information and communication technology and applications. It also integrates *social* dimension (impact on health care, solidarity and social protection, employment and labour market, continuing education and training etc.), *environmental* dimension (impact on resource use and environmental protection), *cultural* dimension (impact on conservation and development of national and international cultural heritage, promote cultural pluralism, the necessity of child protection, multimedia industry development and production of informational content) and *economic* dimension (to develop new paradigms of the digital economy and new economy based on knowledge, innovation, entrepreneurial culture and management, education of the citizen and consumer).

Unlike some other points of view regarding only the economic (the digital economy, Internet market) the knowledge society is not only the knowledge based economy. This is very important, crucial, essential and includes *the use and management of knowledge* existing in the form of technological and organizational knowledge and in the form of the production of new technology through innovation. This is a **New Economy** where innovation is the process of determining where intangible assets are more important than tangible ones. The knowledge society is much more because it provides an unprecedented dissemination of knowledge to all citizens by new means. Using mainly the Internet, electronic books and electronic methods of learning processes (e-learning), the knowledge based economy seeks to extend and deepen the scientific knowledge and truth about life. It is *the only way that will ensure a sustainable ecological society and will be a new stage in culture* (based on knowledge of culture involving all forms of knowledge, including artistic, literary knowledge etc).

Balance between knowledge and resources has changed now to the idea that knowledge has become perhaps the most important determinant of living standards - more important than land, tools and even work.

If ever the world has forged the riches of the earth's resources now humanity faces a new technological revolution through which traditional factories society gives way to "creative society" where the robots come to replace nearly all the labour by hand; the hand but in any case and nowhere, the brain thinking. This leads to the conclusion that the human spirit, creativity and thinking are a source of wealth, a source of development.

The traditional industrial accumulation can not be a progress, but a setback, even "waste of labour and investment", while computerization becomes an opportunity for production and for full use of creative capacity, of human labour. It is not only the full use of people as numbers (each to be employed) but also the full use of native or acquired skills of each.

Accelerating the pace of life (and in particular speeding up production due to automation) means that every minute of "dead time" cost much more than ever, considering the lost goods. The delay is becoming increasingly expensive. Information must be circulated as soon as possible. At the same time, rapid changes, by raising the number of new unexpected problems, increase the volume of information required. We need *more information* to cope with a new problem than for a problem that we solved by ten or a hundred times before.

Noting some exaggeration in the assessment of the roles of the different categories of work, Georgescu-Roegen stated: "Very likely we will soon find unpleasant consequences of what we, the scholars, tried to sow in people's minds. And the truth that awakens - on which it is now appropriate to focus - is that a world composed only of genius, even only of scientists or university doctors could not survive even one minute".

In the spirit of Roegen thoughts, in the real world, whether in the form of the knowledge society, it is an acute need of productive people: farmers, miners, carpenters, steel worker, drivers, vendors, etc. But all these activities require a different understanding, a different intellect which will enable their

successful employment in another kind of thinking, a different behavior. It is here a fundamental principle of social change, which anthropologists experts have made it so: any social revolution, any transition from one civilization to another requires a different type of intellect than those who initiated and led the previous turn.

If we refer only to work of plant grower and breeder we can say that it remains an extremely useful and productive work in Knowledge Society, too. It is taking place under conditions far different from that in agricultural civilization and/or of industrial civilization. Agricultural workers in economically advanced countries successfully use the scientific achievements in the field without being obliged to become creators of new theories in the field, without going into conceptual analysts' category as engineers, biotechnologists, geneticists.

We think that deserves attention some exaggerations in characterizing Knowledge Society which gives the impression that only *actual society is based on scientific knowledge*, that any kind of work requires general knowledge of high scientific level. In connection with this aspect of the problem, there are two categories of explanations.

The first is to clarify remarks made long ago, that always labour, unlike the animal's instinctual activities, was based on acquiring and applying knowledge of the time. Whatever the historical era in which it held, all kinds of work have assumed the unity of physical and intellectual side and have had consciousness.

The second statement we make is the fact that the knowledge society is based on a particular type of knowledge and a special kind of behavior. We believe that these specifications have been foreshadowed by specialists from the nineteenth century, having as background the strengthening economic and capitalist industrial civilization.

In the mid-nineteenth century, Horace Mann was an indication of the role of knowledge and ways of its transforming into national wealth (as stock) and in economic development and growth (as flow): "Our means of education are the important mechanism by which the 'raw material' of human nature can be transformed into inventors and discoverers, into skilled

artisans and farmers educated scientists and lawyers into founders of charitable institutions, into people able to develop ethical and theological sciences.”

W. Arthur Lewis – even if not very recent Nobel Prize laureate – determine and substantiate a “absorption effect of the masses”, meaning that they must have a minimum level of education in order to become intelligent consumers. An illiterate population - continues Lewis - can not appreciate the technological advances and can not benefit from them. Therefore, education is important not only as direct investment in production but as consumer good as well, to allow more people to enjoy the products and services and to better understand their utility.

In the New Economy, there is a shift of activities that require skills to handle and manage to the activities involving the development and application of knowledge. It speaks more and more about the *knowledge worker*.

Knowledge-based workers are those whose jobs require a good training, a high education level. Nowadays, knowledge and training academic standards for employees and managers are very high, much higher than in the past. Employees’ ability to develop strategic solutions, to apply specialized knowledge and collaborate in terms of contextual chaotic demands represents the new essential capability of the organizations. This new form of organization focuses on two coordinates. First, designing organizational structure that focuses on knowledge skills of employees on achieving company goals and second, shaping the culture and behavior of employees within the meaning of involvement and commitment required by the new type of organization.

With these few aspects of the approach of knowledge - scientific and experimental - I wanted to show both the continuous enhancement of its role in past centuries and especially its new features in the context of the Knowledge Society.

In conclusion, we can say that the information, knowledge becomes crucial driving force in the New Economy. In this context we are witnessing an expansion of the importance of human capital, intellectual and social environment and to enhance the role of creativity as key factors for long-term

sustainable development. Third Millennium organizations are learning organizations having the core competence the ability to coordinate all the powers.

The New Labour Content and the Sustainable Development

Șerban Andreea Claudia
Academy of Economic Studies
Andre_serban@yahoo.com

Abstract

The labour content, its structures and the finality of the social action were always in a permanent relation with the historical type of society and with the manner of producing goods and services. The humanity passing to the global economy, to a new manner of economic growth places in front of the specialists, in front of all the rational individuals the problem of explaining and understanding the new way of interaction between the labour and all the social actions with natural environment, with Earth Planet – unique and indivisible. It is a common understanding already that not only the human welfare but their existence itself is in direct relation with the protecting, non-aggressing of the natural indivisible resources. It is already necessary to globally take action in the sense described above because the postponement of this action with 20-30 years, as specialists say, could have disastrous effects for the humanity.

Key words: labour, new economy, knowledge, knowledge economy, sustainable development.

J.E.L. classification: J01, J24, Q01.

The new society type (knowledge economy, knowledge-based society) that exists already in the economic advanced countries seems to become global and to cover in various shapes all the world countries. Taking into account these new conditions, there was a new way of reporting and assessment of the labour content, social structures, its content and the finality of the social aggregated action. It is the global, planetary parameter.

The planetary natural environment, his 'health' became more important now comparing with the regional or national one and most of all comparing with the business

environment of one or other big corporation. All these organisations and institutional structures, all the people that take part and manage them have now a new challenge: "thinking globally and acting efficient locally".

In these new conditions, the actual type of economic growth, based on the industrial civilisation and the capitalism - that is dominating - is now passing a profound crisis period. It is no efficient response to the new challenges of the XXIth century and it is no adapting to the unique and indivisible character of the natural environment. The labour content and aggregate social actions are dominated by the slim importance of the economic advantage, of the profit. In the new global capital (financial) market - as Davin Karten says - "billions of monetary units can come in and come out from an economy to other in only few seconds". The money force becomes so powerful as some specialists, analysts "consider that those that own hot capitals become a phantom world government, a government that is irreversibly altering the concept of sovereign power of national state" (Karten, 1995, p.217).

We have here an important example of the manifestation of the evil side of the invisible hand of the market that removes the efficient production of welfare.

Some authors consider that atmospheric degradation problem catch too much importance, this problem being for the far future. Two opinions are important:

- first one - considering that the damages will be enormous if, in the near future, the urgent natural environment problems will be neglected;
- the second - considering that those problems could be solved in the future using the modern technology. Many followers of this second idea consider that the humanity has more difficult problems that need concern: wars, epidemics, drugs, unemployment, health, terrorism etc.

At the half of the last century the heart of economic theory was dominated by the economic growth, understood as an absolute increase of macroeconomic indicators. In the early '70s it was understood and demonstrated the idea that the traditional model of economic growth faces real energy problems, environmental, etc.

At the first United Nations Organisation Conference on the development, at Stockholm in 1972, it was used the term eco-development. The same year, The Roma Club Report, "The Limits of Growth", help the humanity to understand that the problems of the economic growth are inseparable from those of the natural environment, of the population growth, resource depletion etc. The expression of this new attitude was reflected in UN initiative to found The World Commission on Environment and Development. The first task was to develop studies and provide recommendations to find the concept for that kind of development which should ensure continued growth (and not its stop, as Roma Report suggested), but also the improvement of living conditions and human-environment relationship. Used in the early '80s at the International Conference on Environmental Conservation, the term sustainable development is launched with the publication of the Brundtland Report (named after the then Norwegian prime minister) of the 1987 World Commission on Environment suggestively titled "Our Common Future" (Our Common Future, 1987, p.4).

The report aims to find a development path to support human progress not only in a few places and for some years, but over the whole planet and the distant future. Sustainable development is that kind of development that meets the needs of the present without compromising the ability of future generations to meet their own.

The new concept resulted from the ample discussions on this event, sustainable development, requires a new attitude towards the natural environment, the changing relationship between man and nature in order to establish a new partnership between the two entities, the balance and harmony between them. The sustainable development can not be limited at economic growth only. It should combine harmoniously achieve economic growth, environmental protection,

social justice and democracy, new attitude toward labour.

Over the centuries, societies and individuals have followed two crucial goals, sometimes consistent, sometimes not. First, it is an economic objective: to survive and for this to find necessary goods, especially for food. Secondly is an ethical objective that through the reactions against the abuse of force and care to protect human life appeared in all civilisations but most of all in the actual one (Sauvy, 1978, pp.2).

To effectively linking the two general objectives it is necessary a concerted human action with a global effect determined by the local individuals actions. Thus, it takes "me" to work towards established, but "we" together to have a single purpose, overall progress.

Human life is a continuous sequence of individual actions. But individual action is by no means isolated. It represents a link in a chain of actions which together form an action on a higher level, pointing toward a distant goal. Every human action has two aspects. On the one hand, it is a partial action, framed by an action that aims at further implementation of a portion of the targets set in the perspective of a long battle action. On the other hand, in relation to its own actions pursued by the parties, it is in itself a whole.

The way to achieve great things must pass through the achievement of partial goals. A cathedral is nothing but a pile of stones fit together. But the only method for building a cathedral is to put one stone upon another. For the architect, entire project is the main objective. To bricklayer, it is the wall considered separately, and for its help, every stone taken part (Mises, 1966, p.44-46).

The individual may recognize a conflict between his behaviour as a decision maker and that particular behaviour, generalized to all individuals, that will lead to better results for him. But, by his inability to influence others, he will do his utmost best to handle any circumstance. If this course of action is for all individuals who interact, the overall result is pollution, environmental degradation, a result that ultimately, it is not wanted by anyone.

Of course, we can ask whether two (or many) can walk together without a previous understanding (Buchanan, 1997, p.41;173).

This went shoulder to shoulder would be possible under conditions in which every individual is aware of its effect on others and the environment, pollution of life, regarded as the ultimate value of its objective.

The fundamental social phenomenon which determines the objective of individual human action is labour division and the co-operation in labour. The experience teaches people that co-operation action is more efficient and productive than human individual action. The natural conditions that determinate the output increase for each labour unit used. These natural conditions are:

- innate inequality of people in their capacity to provide different kinds of work;
- the unequal distribution of the un-human production conditions;
- the success of approaches requires larger forces than those of a single man and requires the combined effort of many people. Sometimes it takes filing a workload that one person is unable, because of its capacity is too low. Other objectives could be achieved by a single individual, but the time he should dedicate to work would be so long that the result would be achieved only later, and would not compensate the effort. In both cases, only joint efforts are possible to achieve the goal. Society is much more than a temporary alliance concluded for a specific purpose and which is terminated once the target is achieved.

Amartya Sen consider that fundamental liberty of using our responsibilities depends on personal, social, environmental circumstances (Sen, 2004, p.347).

Knowledge society having in centre the human, gifted with a good stock of knowledge, competencies and skills according to the values arising from knowledge is able to find "sustainable" solutions for current issues. First it will change the role of raw materials in terms of their contribution to economic performance and thus will reduce the pressure on the environment and natural resources. Secondly the new technology will enable significant reductions in raw materials incorporated in their production and at the same time production processes will increasingly affect the environment less.

In the knowledge economy inventive and creative abilities of people will generate

economic productivity, lower the cost conditions in particular in areas such as energy, natural resources and environmental protection. Existing knowledge can lead to man's reconciliation with nature if the benefits of knowledge are used towards protecting nature, not only for economic purposes only. Science, technology, knowledge should not be used as weapons against nature, the problem is not having a winner and a loser, but to find a match between the two. The purpose that matters and should be taken into account is not the immediate, but the final one, Survival.

If, in general, so far, man has not understand or has not been able to maintain or replace the action for the recovery and purification carried out by nature, his action must now be directed towards behavioural changes and necessary actions for classification of human existence on earth real potential parameters, not the ideal or assumed.

Human work should be in perfect union with nature. Acting upon nature through work in order to obtain supplies necessary to meet various needs, human should not overpower nature, he must adjust to the demands imposed by it and to return to her.

It becomes an obvious reality that all countries are facing today the problem of environmental pollution. This process generalises and transforms into a problem of entire humanity. Process between man and nature must be one-way, which is transmitted from man to nature as a result of human action must not only be negative processes but also processes that aim to preserve and protect the environment. In this sense, the innovation in all the economic areas determines the transformation of human resources and their production capacity in conjunction with environmental needs of economic, social, environmental in which they operate.

Technological innovations are a means of ensuring human development due to the impact they have on economic growth as a result of the contribution of technology to increase productivity. Technological advances in agriculture, medicine, genetics, manufacturing and communications were important factors in human development gains achieved. Comparative studies suggest that technological changes have an important

contribution to development, as elements justifying the differences recorded between the growth rates of different countries. On the other hand, technological innovations are the expression of human creative potential; human development is an important means to support technological development. (Suciu, 2002, p.142).

Scientist Syent-Györgyi Albert stated that "We live in a new world for which man was not ready. Survival now depends on the extent to which he can adjust quickly and well in this world, reshape all his ideas, all his social, economic and political structures" (Syent-Györgyi , 2006, p.266).

Man by his action is able to solve all problems and we have still reason to fear that these problems have not way out. It is the man who created the technological diversity of these paradigms lead at the break and he will be the one who will be creating a new "wealth of nations" through knowledge.

The question about the limits for pollution is due to the labour and human. Until the invention of the internal combustion engine there was no question of restricting the freedom of individuals to disperse the various materials into the atmosphere. In '70s these limits were already necessary. Technological changes are not the only factor of this process, but its amplitude makes it the most important factor to accelerate breaking the balance between man and nature.

The solving of this problem requires co-ordination of technical dimension with the economic one within the general economic system. Economic and social development is driven by technology that creates not only risks, creates a means to control them.

The preoccupation for increasing economic efficiency neglected the costs supported by nature, in all European Union countries, including Romania. That is why we have to take into consideration the costs for nature renewing, for environment protection and development in the new economic efficiency definition. The last one takes economic, social, ecological efficiency dimensions because the society can not develop without a perfect harmony with the nature.

As we shown before, sustainable development merge the interests of protecting natural environment and increase of population with development strategies

(national, regional, global) having as final result a relative and dynamic equilibrium between economic growth, cultural development, science and technology progress, natural environment protection.

Consumer Behavior Determined by Social Classes

Șerban Comănescu Adrian
Muhcină Silvia
„Ovidius” University of Constanța
adrys_serban@yahoo.com

Abstract

Information on consumer behavior is essential in trade policy decision-making process.

The study of consumer behavior has concerned different subjects: psychology, sociology, economy. In a marketing approach knowledge of consumer behavior is not an end in itself, but only a tool, a means by which business decisions are adapted to the consumer expectations.

Key words: consumers, marketers, social classes,

J.E.L. classification: M31

1. Introduction

Marketing aims to meet the needs and wishes of consumers and satisfy them. But consumer knowledge is not a simple thing. It is possible that they express their needs and desires and act in a totally opposite way; sometimes may not even know his real motivation which drives them to buy, or to react to factors modifying their purchasing decisions in the last minute.

Marketers have the task of analyzing desires, the perception, preferences and purchasing behavior of consumers concerned. This analysis will allow the creation of products, with new features, price formation, the choice of distributions channels, development of advertising messages and other elements of the marketing mix.

2. The analysis of the consumer behavior

One of the most popular definition of consumer behavior is given by the American Marketing Association: "a dynamic interaction on the impression and perception,

behavior and natural events policy, which directs human beings changes in their own lives." ("American Marketing Association", in BLYTHE J.-work.cit.p.10-11.)

A more concise definition belongs Engel J.F, Kollat D.T and R.D. Blackwell: "all acts of individuals directly related to the purchase of good and services, which includes all decision-making process that precedes and determines the acts." (Engel J.F., Kollat D.T., Blackwell R.D.-Consumer Behavior, Holt, Rinehart and Winstone, Inc. New York, 1968, work cit DOBRE, C. Comportamentul consumatorului, Orizonturi universitare Publishing, Timisoara, 2000, p.14.)

Consumer behavior refers to "mental decisions and actions of people involved, primarily in purchasing goods and services." (Ristea, Ana-Lucia (coordinator) –work.cit. p.174)

Consumer behavior can be seen in the narrow sense- about goods and services in a broad sense- in the fields other than business: faithful behavior, voter behavior, the behavior of union members .

Factors that determine consumer behavior can be grouped into: internal factors (individual explanatory variables) and external factors(sociological variables).

In our view, we chose to talk about social classes and their implication in determining consumer behavior and training. Social classes are part of the external factors.

„Social classes. These are defined as groups of persons, who hold a position close in the company, in terms of behavior and opinions as a powerful differentiating factor in the bosom of society.

Social classes can not be sighted by a single indicator, but must rely on many factors such as: income, occupation, education level, type of dwelling, how leisure, etc.

Typology of the best known is the one proposed by Warner, which distinguishes six classes:

- upper/upper;
- upper/lower;
- middle/upper;
- middle/lower;
- lower/upper;
- lower/lower.

For example, in developed countries, upper class is the lowest (0.5% of the population) and consists of the old family (at least three generations in the same class) whose places of residence are international. It is, for example, the big industrialist or bankers. Their consumption structure differs significantly from that of other classes. In fact, they consume fewer goods and use in a decisive measure to the market. This is because goods are passed from one generation to another.

Warner proposed classifications is less used in some countries such as France, Spain, Italy, where people prefer to distinguish four classes:

- A, class of the rich people which represents up to 15% of the population;
- B, 30% upper middle class;
- C, 40% lower middle class;
- D, modest grade of 15%.

Another classification takes into account socio-professional categories: farmers, working, their own land, artisans, merchants and business owners professions educations, officials workers, pensioners, other people without employment.

Distinction in social classes is an essential criterion of market segmentation, but two points should be made:

- lack of opportunities for measurement, income is often the only criterion used to define membership in a class, which can lead to masking the real membership;
- there is a very clear distinction between a class and another, all individuals being placed on the same axis, but some elements are significantly changed" (Meghisan Gh, Nistorescu T, Adrian Serban Comanescu, Bazele, Marketingului, Universitaria Publishing, Craiova, 2008, work cit p 95-97)

3. Conclusions

Information on consumer behavior is essential in trade policy decision-making process.

The study of consumer behavior has concerned different subjects: psychology, sociology, economics etc.

In an approach placing marketing, knowledge of the consumer's behavior is not an end in itself but only a tool, a means by which business decisions are adapted to consumer expectations so much.

A Relationship between the Degree of Search and Evolution of Assets

Serban Florentin

Academy of Economic Studies, Bucharest

florentin.serban@csie.ase.ro

Buşu Mihail

"Spiru Haret" University of Bucharest, Faculty of Mathematics and Informatics

m.busu.mi@spiruharet.ro

Abstract

In the first part of the article is described the evolution of the major financial assets in recent years. Further are analyzed the "most wanted" financial asset classes in 2010 with a study done on Google Trends. At the end of the presentation is evaluated the evolution of these assets in 2011, is this way we are trying to make a connection with their search volumes.

Key words: optimization; investing; asset classes; evolution.

J.E.L. classification: G01, G10, G11

Note that U.S. dollar can buy now only 10% of goods and services that could be purchased in 1950. In what is better to preserve capital? To find an answer, we follow the benchmark of three asset classes: stocks, bonds and real estate. We analyzed performance in real terms, given the SP500 index, the average price of new houses and U.S. government securities with a maturity of 10 years. In the chart below we can see the performance (adjusted for inflation) in each asset class year period from 1960 to 2010.

Figure 2: performance of financial assets between 1960 and 2010

source: www.primet.ro

1. Where do we put our money?

Many times, when the investments have a reduced time horizon, the effect of inflation is neglected and negligible. If the investment is made in order to preserve the capital so that it will be used at some point in future (as if saving for retirement), the effect of inflation becomes evident. The graph below tracks the real value of a dollar, cash retained from 1950 to 2010.

Figure1: Evolution of a US dollar kept cash between 1950 -2010

source: www.primet.ro

Table1: performance of financial assets between 1960 and 2010

5 years	S&P500 (%)	Real estate (%)	Bond (%)
1960 - 1964	10,79	8,5	4,05
1965 - 1969	0,68	0,15	5,35
1970 - 1974	-5,70	2,64	6,82
1975 - 1979	3,41	1,96	8,20

1980 - 1984	6,21	-1,71	2,43
1985 - 1989	15,05	4,02	8,76
1990 - 1994	6,15	-1,95	7,27
1995 - 1999	25,48	2,51	6,00
2000 - 2004	-2,41	3,86	4,74
2005 - 2009	-2,21	-3,35	4,10
1960 - 2009	7.1	1.34	4.78

source: www.primet.ro

Remarks:

1. Investing in S&P500 had the highest annualized average return (adjusted for inflation), followed by investment in bonds, and only then the real estate, which is consistent with value-added and with characteristic of each investment risk.
2. Return of the real estate investment is minimal because they do not produce added value, but the performance is less than inflation due to the constant rise in demand.
3. Due to the intermediary costs (state or bank) and the risk premium, return on bonds is with 33% lower than of the return of the stocks.

2. The most "wanted" asset classes in 2010 and their yields.

Until recently, gold and oil were less active demand by individual investors. Bankruptcy of the Lehman Brothers and the ensuing economic instability has created the need to invest in something tangible, such these assets are returned as the attention of investors. Investors' interest in different asset classes was very difficult to quantify or measure. With the advent and widespread adoption of search engines, such estimates have become much easier. In this case, a good indicator of investor interest would be the volume of searches performed on Google for that asset class. The tool used for this study is Google Trends (<http://www.google.com/trends>). There were taken into account the search volumes for "gold ", "oil", "stock" and then the evolution of the share of each word in 2004-2010.

Gold: Of the current analysis, most wanted was gold. Its share in total search volume has increased over the 2004-2010 average, something that could be explained and presented it an attractive yield (25% in 2010).

Figure 3: share of searches of the word 'golden' in 2004-2010.

Source: www.primet.ro

Oil: Although oil yield in 2010 is very close to 0, the share of search volume has increased significantly compared with the average of the years 2004-2010. It is possible that this will be significantly materialized by a good performance in 2011.

Figure 4: share of searches of the word 'oil' in 2004-2010

Source: www.primet.ro

Stock: If in 2009 the interest for stocks came back, the year 2010 did not indicate a significant appreciation of investment interest for this asset class. The about 15% yield in 2010 (SP500) is not evidenced too much .

Figure 5: share of searches of the word 'stock' in 2004-2010

Source : www.primet.ro

Conclusion: Whatever the asset, or combination of assets chosen, it should be noted that a simple Google search can greatly assist us in taking the decision.

3. Evolution of assets in 2011

Gold: considered a "reserve asset", to which investors withdraw to protect themselves from either a high inflation or financial market turbulence. Thus, the gold price fluctuation is mainly given by investor's sentiment data from what is happening in the world economy.

Evolution: yield + 1%
03.01.2011, P₁=1.414; 22.03.2011, P₂=1.424;

Figure 6: Gold price evolution in 2011

Source: www.forexfactory.com

Oil:

Evolution: yield +14 %
03.01.2011 Price: 91.520;
22.03.2011 Price 104.290;

Figure 7: Oil price evolution in 2011

Source: www.forexfactory.com

Stocks:

Evolution: yield +1.65 %
03.01.2011, Price: 11.826;
22.03.2011, Price 12.022;

Figure 8: Dow Jones price evolution in 2011

Source : www.forexfactory.com

4. Conclusions

It may be established a directly proportional relationship between the amount of an asset search and its evolution (for oil and stocks). However, in an investment, is better to keep track of the account and politico-economic context (for oil and gold).

The Management of the Translation Services

Abstract

Managing translation services' have become buzz words in translating across cultures. Nowadays, translation agencies are faced with numberless problems. The usual assumption is that, unless a specific purpose is specified by the customer, a translation is provided for information purposes only. The translator is a negotiator and a mediator between two cultural systems. S/he attempts to naturalize a different culture, to make it conform to what the target readers are accustomed to.

Key words: *intercultural, competence, negotiator, mediator, gap*

J.E.L. classification: F50, F51, D83

It is common knowledge that the ability to speak a foreign language immediately implies the ability to translate into that language. Thus, the translator needs to have the command of both the SL (source language) and the TL (target language). The word 'translation' may refer to:

- both the translating process and its product
- the product of the process of translation (the translated text)
- the process, the activity performed by the translator

It is an established fact that translation as a profession has become a cost-led industry though it should not be viewed as such. Nowadays there are numberless companies dedicated to the provision of the translation services. Generally, such companies have their own staff translators that have been assessed and tested to ensure that they have appropriate skills for this purpose.

Seen in another light, translation is a craft, a science that implies a creative process. If one regards translation as an art, things begin to change because creation implies effort, a struggle to find the right words, to obtain the atmosphere desired and to share interest.

There are different opinions regarding the (un)translatability of a text. Translators put forward two extreme views: *either everything can be translated without loss or that nothing can be translated without loss*, as in the Italian expression *traduttore/traditore*/'translator/traitor.

In Peter Newmark's view (1995: 6), "everything without exception is translatable; the translator cannot afford the luxury of saying that something cannot be translated". Following Newmark's principle, the translator will understand that every problem has a solution. The translator should attempt somehow to create the same atmosphere so that the TT (target text) may have the same impact upon the TL (target language) speakers as the ST (source text) has upon the SL (source language) speakers. Moreover, P. Newmark (1995: 6) emphasizes that "translation has its own excitement, its own interest. A satisfactory translation is always possible, but a good translator is never satisfied with it. It can usually be improved (...). A translator is always trying to extend his knowledge and improve his means of expression".

1. On defining Culture

Culture is an important factor in the translation process. Translators should be aware of the cultural element because it is central to a theory of translation. We share Susan Bassnett's opinion (1991) that culture becomes the operational unit of translation.

The term 'culture' is very hard to define. Fons Trompenaars and Charles Hampden-Turner (qtd. in Katan 2004: 25) have been studying the ways culture affects business. They admit that:

"In twenty years, we have seldom encountered two or more groups or individuals with identical suggestions regarding the concept of culture". Moreover, they put forward a model of culture comprising three rings or 'layers of culture': the outer layer (artefacts and products), the middle layer (norms and values) and the core (basic assumptions about life that have been handed down unconsciously from generation to generation). This model of culture comes from some of the major influences on training in culture for the business community.

The English anthropologist Edward Barnett Tylor (qtd. in Katan 2004: 25) formulated one of the oldest and most quoted definitions of culture: "Culture is that complex whole which includes knowledge, belief, art, morals, law, customs and any other capabilities and habits acquired by man as a member of society".

Compiling a list of 164 definitions, the American anthropologists Alfred Louis Kroeber and Clyde Kluckhohn (qtd. in Katan 2004: 25) formulated their own definition as follows:

Culture consists of patterns, explicit and implicit of and for behaviour acquired and transmitted by symbols, constituting the distinctive achievement of human groups, including their embodiment in artefacts; the essential core of culture consists of traditional (i.e., historically derived and selected) ideas and especially their attached values. Culture systems may, on the one hand, be considered as products of action, on the other hand, as conditioning elements of future action.

According to Katan, culture is not visible as a product. It is internal, collective and acquired rather than learned. Katan (2004: 26) also mentions that the word 'culture' derives from the Latin words *cultus* ('cultivation') and *colere* ('to till'). Moreover, he mentions that as seeds continually absorb elements from the land to ensure their development, so do people. They absorb vital elements from their environment

which influence their development within the human system.

2. The Translator as a Cultural Mediator and Negotiator

The words 'culture' and 'translation' are being increasingly linked. As mentioned above, the cultural horizon is a general requirement for a translator involved in the translating process. This is a problem of great complexity if we consider that the negotiators of international economic affairs act in different cultural environments.

Translation is the exploration of a gap between cultures. The translator will mediate between two language cultures in converting LC1 (language culture) into LC2. The translator's cultural competence and knowledge is very important as s/he does not simply search for an "equivalent". His/her intention is to express the same reality through LC2.

The concept of cultural mediator was introduced by George Steiner (qtd. in Katan 2004:16) who believed that "the translator is a bilingual mediating agent between monolingual communication participants in two different language communities". The translator is also a negotiator, that is to say, he has to make choices according to the situation of translation. The focus is on effective communication and understanding between the service provider and client while respecting the client's cultural and language needs.

If translators do not include culture as part of the translating process, they will be classified as mere transcribers, copiers, stuffers and sealers. As Ronald Taft (1981: 53) puts it:

A cultural mediator is a person who facilitates communication, understanding, and action between persons or groups who differ with respect to language and culture. The role of the mediator is performed by interpreting the expressions, intentions, perceptions, and expectations of each cultural group to the other, that is, by establishing and balancing the communication between them. In order to serve as a link in this sense, the mediator must be able to participate to some extent in

both cultures. Thus a mediator must be to a certain extent bicultural.

In the chapter entitled *The Translator as Mediator*, Basil Hatim and Ian Mason (1990: 128, 223-24) discuss the following:

The translator is first and foremost a mediator between two parties for whom mutual communication might otherwise be problematic and this is true of the translator of patents, contracts, verse or fiction just as much as it is of the simultaneous interpreter, who can be seen to be mediating in a very direct way.

According to the authors, there are two specific ways in which a translator is a mediator:

- bi-cultural vision

Hatim and Mason deem that the translator's role is to identify and resolve the discrepancy between sign and value across cultures.

- critical reader

They also argue that the translator is a 'privileged reader' of the SLT (source language text). In other words, s/he will have the opportunity to read the text carefully before translating.

Mary Snell-Hornby (qtd. in Katan 2004: 21) describes the translator as a cross-cultural specialist. She assumes that the translation process can no longer be regarded as being between two languages but between two cultures implying 'cross-cultural transfer'.

Lance Hewson and Jacky Martin (1991: 133-155) view the "Translation Operator as a Cultural Operator. Their aim is to "underline once again the [Translator Operator's] social-cultural identity as being one of the many factors which account for translation being what it is"

Hatim and Mason (1990: 11) sustain the same idea: "inevitably we feed our own beliefs, knowledge, attitudes and so on into our processing of texts, so that any translation will, to some extent, reflect the translator's own mental and cultural outlook, despite the best of impartial intentions"

With regard to the competencies a mediator must possess in both cultures, Ronald Taft (1981: 73) mentions the following:

- Knowledge about society: history, traditions, customs;
- Communication Skills: written, spoken, non-verbal.

- Technical skills: the skills required by the mediator's status, e.g. computer literacy
- Social skills: knowledge of rules that govern social relations in society and emotional competence, e.g. the appropriate level of self-control

The most important factors of translation are intention, meaning, tone, the impact, the texture and function of the translated text (in our case the play translated to be read or to be acted), the text as a unit. We share Peter Newmark's opinion that "there is continuous tension between the maximal unit - the text and the minimal unit - the word". The translator has to make his or her own choices as to which meaning(s) he has to transfer depending on what he/she considers to be the writer's intentions.

As Dollerup (2006: 57) puts it, "translators are not perfect (...). However, in the real world, the sending side involves not only an individual author, but frequently also a client who also has some reasons for having a translation done".

In other words, the translator's competence is proved by his/her ability to analyse, compare and convert two cultural systems, at the same time respecting both the conflicting forces within one LC (language culture), and the interplay of these forces as the language cultures are brought into contact.

The translator's cultural competence and knowledge is very important because s/he does not simply search for an 'equivalent'. Lack of knowledge will affect the translator's competence. The cultural elements are considered to be the ground of a potential distinction, difference and tension. Basically, the text is situated in the middle and represents the centre, the main preoccupation of all factors involved. What a translator should do is to establish a balance between all of them or to make them equivalent. Equivalence in translation and absolute synonymy may never be achieved not even among words belonging to the same language, not to speak of those belonging to different languages.

To conclude, the mediator has to be flexible in switching his cultural orientation. Hence, a cultural mediator will have developed a high degree of intercultural sensitivity, and will have reached the level of 'contextual evaluation'.

3. The Customer-Service Provider Relationship

In the translating process, quality gaps may arise unless there is clear specification of the customer's needs. There may be instances in which gaps may arise between what the customer expects and the project manager's understanding of what the customer desires. In this case, the communicative purpose is misunderstood in the process of translation. The customer may expect an edited translation whereas the project manager deems that the translation has a mere informational purpose. There are other instances in which the project manager does not clearly specify what is required. Quality gaps may also arise when the translation is longer than expected. In this situation, the delivered translation does not correspond to what was specified by the customer.

As an outcome of these situations, the main quality objectives in translation should be mentioned:

- to understand the customer requirements so that no quality gaps arise and the customer requirements are met.
- to provide the resources to meet the requirements of the work.
- to provide the appropriate linguistic skills and experience.
- to provide an accurate translation.
- to use terminology appropriate for the intended use.

It is an established fact that conceptual terms are becoming easier to translate. For instance, translating new technology across cultures will certainly not create problem. At the technical level, communication is explicit, and ideas are consciously conveyed. It is the dictionary denotative meaning that needs to be translated. This form of culture is indeed now global, with business and industry working to the same standards throughout the world.

At the technical level, negotiation of meaning is reduced to the minimum. In this respect, Peter Newmark (1988: 6) states that: "No language, no culture is so 'primitive' that it cannot embrace the terms of, say, computer technology". Thus, at the technical level little or no loss of meaning may occur due to the fact that communication at this

level has no extra-linguistic context. That is to say, the text is the authority, and the message is clearly conveyed. Anthony Pym (2000: 189) calls translation at this level NANS or rather "no-addition-no-subtraction". It is also at this level that the business community is most aware. A translator without the technical language skills will clearly not be effective. In these cases, a successful translator will not only need to have a native command of both languages but will also need to know where to find technical information efficiently: from dictionaries, encyclopaedias, glossaries, thesauruses, on paper or on the Internet. The Internet has become a useful tool in providing on-line translation assistance in a variety of forms.

The fact should be mentioned that understanding the meaning of the ST is crucial in the translating process. Federica Scarpa's (qtd. in Katan 2004: 82) surveys on specialized translation treats topics of polysemy, (partial) synonymy and concludes with the following warning: "There is then, the constant danger that a translator will confuse the specialized use of a word with the more common". It is generally known that software programs make these translations as good as the native human translator-and require only minimum post editing.

Technical concepts, such as satellite communications technology, have to be discussed, negotiated and implemented by people working within their contexts of culture. People, as representatives of their culture, do things in different ways, and usually out-of-awareness. Newmark (1988: 156), in fact, cautions about "the possible cultural and professional differences between your readership and the original one", and explains that these will need to be taken into account when approaching a technical text.

In the discussion about the provision of translating services to the customer it is best to assume that the latter has little knowledge about the requirements. The customer should not be treated in a patronizing manner but be offered advice and guidance. The customer may be informed about translation needs with a degree of diplomacy. As a rule, the majority of customers are informed but a customer education is always needed. It is an established fact that translation has become a

cost-led business. A number of situations may occur regarding the service provider-customer relationship.

One of these problems may be that the customer has little knowledge about what is involved in the provision of the end product. The situations in which a customer may verify the quality of a translation are rare. What the customer should be informed about is that the least expensive translation is not likely to be the best quality translation.

The customer-service provider relationship should be based on communication and translation needs should be an integral part of it. Nonetheless, the customers are exposed to some risks. They are in danger of accepting lower prices from less qualified translators. This situation may result in the fact that the customers may not use the product appropriately which leads them to additional costs.

There are, however, typical misconceptions regarding the customers' expectations:

- The translator can work in numberless languages
- The translator is able to tackle all subjects
- The translator is available at any time
- Checking the translation takes no time
- The translator may accept any reward
- The translator can produce a perfect translation

The fact must be mentioned that the perfect translation is a chimera. The notion of perfect translation presupposes that both the ST and the TT are comparable in all respects. Moreover, it is presumed that both the source and the target cultures have identical cultural and economic systems. Since languages are not stable, one expression will not always mean the same. Therefore, the notion of perfect translation is tackled by people who do not know anything about translation.

As a conclusion, translators should not be seen as mere photocopiers or walking dictionaries but perceived as agents in creating understanding between people from different cultures. This implies the fact that cultural mediators need to be aware of their cultural identity and understand how their own culture influence perception.

Abstract

The impact of Internet services in the economic field is huge and has generated new forms of performing typical activities in the new e-way: e-commerce, e-banking, and so on. The paper focuses on the impact of Internet, more generally, of ICT (information and communication technology) facilities, upon the economic activity. The aim of this paper is to highlight the limitation and opportunity of electronic environment analyzing some important elements that can stimulate the economy at community level, national level and mostly on the global level too.

Key words: e-business, electronic environment, information society

J.E.L. classification: L81, M21

1. Introduction

According to Oviatt and McDougall, in 1994, it is recognized that many firms are „born global” and initiate international business from inception or shortly thereafter. They have been influenced by both globalization and the impact of new ICT technologies.

Clearly, new Information Communication Technologies (ICT) and the Internet, in particular are providing firms with new ways to conduct business and to exchange and communicate ideas and information [1].

These technologies enable such firms to improve their efficiency and develop new ways to co-ordinate their activities often in an international context [2]. Many authors contend that the Internet offers firms an

invaluable resource for use in internationalization activities, as at a stroke they may have global reach via a website [3].

As Kobrin [4] comments, “cyberspace and e-commerce are intrinsically international”. Web access is available to all firms regardless of size, offering benefits which include: the reduced importance of economies of scale, lower marketing communication costs, greater price standardization, reduced information float time, temporal asynchronicity, increased contact between buyers and sellers, and changes in intermediary relationships. Eastern Europe can take advantage of Internet, more than other part of Europe did. The Internet offers a new means of maintaining and developing relationships with clients, channel partners, suppliers and network partners[5].

While the economic slowdown is still affecting the most markets, there is evidence so far that the online retail market has remained steady due mostly to the lower prices and convenience offered via e-commerce. According to Emerging Europe Monitoring the spending on online advertising also continues to grow in the face of economic uncertainty and in 2010 online advertising should account for around 13% of overall ad spending worldwide.

The primary objectives should be to reduce risks identified in electronic environment, to enhance the trust in this e-markets, to improve the tradability of money market instruments, and generally to ensure compliance with world best practices. The intention is that the above objectives will be achieved by the creation of an advanced technical infrastructure, and a integrated legislative market which will enable the e-business process.

2. Features for resourceful online, e-business and e-commerce

The world e-commerce is now in the adult period, of internal stability. It has overcome a few major crises (the unjustifiable collapse of the dotcom unwarranted multi-sites and the multiannual crises arising from losses/thefts of millions of complete data cards, now a global economic crisis), it is trying to change its appearance by adopting some new universal standards (from 3D Secure, Verified by Visa MasterCard Secure Code up to SmartCards and others) and tends towards efficiency and normality.

Also on the 13th of November 2006, the National Association for E-commerce (ANEC) was founded, whose purpose is to promote and develop e-commerce industry in Romania. Following the dialogue with the representatives of this new industry, ANEC already comes to their support with 5 main projects aimed at:

- helping newly established virtual stores to overcome the initial problems, by obtaining special conditions from the collaborators,

- to make the benefits of online shopping known to the general public and to present the recommended steps in Internet shopping under safe and comfortable conditions,

- to rate e-commerce sites, depending on meeting certain standards, in order to increase the confidence of the purchasers in online businesses,

- to provide both online stores and end users a tool for real time monitoring and reporting of online fraud/complaints and to start a program

- to educate the market, to inform the end consumers in order to increase the usage of online electronic payment.

To develop the e-business you need high-quality information society services. The definition of information society services already exists within the EU law (ANNEX 1: Directive 98/34/EC and Directive 98/84/EC). This definition covers any service normally provided for remuneration, at a distance, through electronic equipment, of data processing (including digital compression) and data storage at the individual request of the service recipient.

The information society services cover a wide range of economic activities carried out online. These activities are able to, in particular, consist of selling goods online. Activities such as delivering goods as such or providing off-line services are not covered. The information society services are not only restricted to services which result in online contracts, but, to the extent they represent an economic activity, they extend to services not paid for by those who receive them, such as services providing online information or commercial communications or those providing data search, access and retrieval tools.

These directives only apply within the European Union, to the service providers established here and cover all services of the information society: services provided between businesses, services between enterprises and consumers, services provided free of charge to consumers which are financed, for example, by revenues from advertising services enabling on-line electronic transactions (interactive Telesales of goods, online shopping). This Directive also applies to other activities, such as: online newspapers, online databases, online financial services, online professional services (law, medicine, accounting, real estate agencies), online entertainment, marketing and direct online advertising and Internet access services.

The information society service providers are subject to the national legislation of the state in which they reside. The place of establishment means the place where an economic activity is actually performed, using stable headquarters, on an indefinite time period. Using technical means and technologies necessary for providing service for other areas does not in itself constitute provider's headquarters.

The obligation of following a procedure for opening a website, with the exception of sites regarding regularizing activities (ex. e-banking services) is contrary to the directive. Member States are also prohibited from imposing regime of prior authorization concerning the information society services, other than those applicable to similar services provided in other ways.

Member States should legislate the providers' compulsoriness to enable an easy, direct and permanent access of the service

recipients and competent authorities, at least to the following information: provider's name, geographic address where the service provider resides; service provider details, including the electronic mail address where he can be quickly contacted, if the service provider is registered in a trade registry or similar public register, the trade registry where the service provider is registered and the registration number, or the equivalent identification means in that registry; if the activity is subject to an authorization regime, the details of the relevant supervisory authority. The Directive obliges Member States to remove any prohibition or restriction on the use of electronic contracts.

Member States shall ensure that in case of a disagreement between an information society service provider and the recipient of the service, their legislation does not prevent the use of extrajudicial dispute settlement mechanisms, available within internal law, including that through appropriate electronic means.

Yet, the Directive provides three types of exceptions:

1) Member States may adopt measures limiting the free movement of services originating from another Member State for reasons relating to the protection of minors, health or consumer's protection.

2) Certain defence activities, such as defence in front of justice;

3) The country of origin clause does not apply to specific areas (ex. copyright rights);

The attention given to the on line services, mostly from the part of the banks but from all of the other companies too, is being determined by the innovative effects that are being felt due to the expand of information society and the internet and also of the electronic networks on the increase of receipts for those who enlarge the economic activities on the internet. For examples we can highlight here the economical impact of Facebook in this information society.

If in Western Europe Facebook has a great impact for economy, in Romania we are at the beginning of the road. We do not have enough Romanian online shops on Facebook to be able for measuring profitability. There are opinions according to which Facebook is much more suitable to promote or trade just some products not all types of products or services. The more exotic they are, more

passionate, more interesting, they will better sell on this new environment. This is supported by information society too. On the other side, in countries that have a great number of users with access to the internet, the way the normal online commerce is well developed, could be a reason why online shops migrated on Facebook have been more successful than in Romania. As any environment, newly won territory by the users, Facebook still has a long way until it becomes a favourite environment for shopping. Users who enter Facebook are more open to activities within entertainment than activities linked to the electronic commerce. But this thing is evolving and as Facebook becomes the second internet it will surely become an adequate environment for shopping.

Facebook is a social, friendly environment where the actions of the users are being interpreted mostly towards entertainment, personal space, relationships with friends. If there are products that can improve these relationships, products discussed inside the social groups or products that raise controversies, then they will be better sold on the Facebook. The good and tasteless, grey products will be sold much harder, at least at this moment of time. When we will use Facebook as a main environment of accessing the internet, then the array of products sold will enlarge and will become as large as the unsocial internet.

But there is an old saying in commerce that goes like this: "you must be present there where your clients are". If almost 3 millions Romanians have accounts on Facebook this means that traders must be there too, at least to try that the brand they represent be present for the users of the Facebook. We think that this moment of the Internet development and the use of Facebook the online shops will have in the near futures high turnovers by using this kind of commerce, the Facebook commerce.

The online environment is evolving and the coming year announces the increase of its impact. For the year 2011, specialists in online marketing anticipate the increase of the role of public opinion, of socializing networks, the necessity of developing sites dedicated to the intelligent phones as well as the appearance of motors of visual search.

The online commerce is changing rapidly,

and this makes the consumers have great expectations too. The adopting of the newest technologies can re boost business and of course increase sells. It is obvious that we enter a new era where the internet makes the rules. Now, at the beginning of 2011 most specialists in online business make an assessment of the efficiency of techniques used last year and come with forecast for the following year.

Adam Audette sees as general tendency for 2011 the change of the internet in a deal frontier where price is the king and the comparison of the offers is instantaneous. The consumer is mainly preoccupied by the price of the product or the service. No longer devoted to the brand, but to the best price! Today the online consumers hunt for discounts, vouchers and free transport. ComScore shows us that the third quarter of 2010 as compared to the third quarter of 2008 the sells of non brand products or the generic ones have increased in a percentage of 10-12%.

Those who want to be in front next year must follow the advice of Ann Donnelly and plan their whole activity in time. Also they must make sure that the site totally allows them to add, edit and improve the pages with novelties, special offers, and advertisements any moment. To have headlines and unique descriptions of the web pages in order to ease the SEO activity and to be present in socializing networks. To make sure that the searching items access the complete content of the sites, that they use key words in most relevant places and that the download speed is high. Maybe most important is that they use the language of the consumers [6].

These tendencies come into being within the international context of the economic development, mostly of the appearance of the developing economies. According to the studies of trendwatching.com cited in marketingcharts.com the developing economies become a continuous source of innovation with the consumers, an attitude that is more and more developing at a global scale.

The growing middle class that has been formed in these countries has special needs and high demands and this leads to a continuous innovation of services and products. The great entrepreneurs direct their attention towards these markets and tally to

their demands.

Last year 2010 we applied a questioner in our town Sibiu on a representative sample of 950 persons. This study aims to interpret the answers to the questionnaire presented to a representative sample of people, whose interpretation will provide valuable information to e-business players looking to expand their online market, to traders and also to the consumers of this kind of trade.

An important aspect resulting from our study is building up the profile of the person who makes online purchases. This person has a higher income and higher education. The average income of non-buyers is 925 RON / month, whereas that of the buyers is 1.892 RON / month.

The lack of an educated and well defined middle class leads to a clearly lower number of Romanian online buyers than that of the foreign countries, yet the current phase of economic recession combined with a more affordable Internet access and better prices in electronic trade have led to an increased interest in online acquisitions.

An important fact observed due to the study is the high percentage of customer loyalty. 77.25% of those who have shopped online a year before they went to buy new products from the same shop on the Internet, becoming loyal customers. This is one reason we are seeing for more and more business to go online and develop electronic business if they intend to have profits despite this economic crises we are passing through.

3. Conclusion

The Internet has redefined how businesses operate and has changed the way people work, with both Internet hardware and software prices' dropping to such a level that fast Web access is not only affordable but essential to business activity. Case firms reported that they were using the Internet and associated technologies to varying degrees in order to reshape business processes, including, manufacturing, marketing and sales and human resource functions as well as administration.

The internet and www have inspired the entrepreneur of the world and have entailed a wave of creativity and the technology of information has allowed a series of new business models.

The European Union as an Answer to Global Challenges

Sorici Costin Octavian

„Ovidius” University of Constanta, Faculty of Economic Sciences
costin.sorici@pms.ro

Abstract

The question is whether Europe wants to actively shape globalisation and wants to proactively address global problems that also have repercussions on European polities. The EU is an endeavour to pool national sovereignty in order to gain political clout at the international level. Global risks and opportunities need to be managed, and the EU will be increasingly expected to act. International development is one of the important strands of the EU's external relations, as it addresses root causes of conflict and includes work on global public goods. Given this context, this briefing paper will outline the background for policy-making in EU development policy. We will be going to explore three areas in more depth: (i) engaging with new actors, (ii) combining energy security, democracy and development and (iii) addressing climate change.

Key words: globalization, European cooperation, climate change development

J.E.L. classification: F02, F15, F43

1. Recent evolutions in international development cooperation

Over the transition period following the end of the Cold War in the 1990s, Western donors and numerous recipient states came to an agreement on a consensus for international development co-operation. Europe actively engaged in this consensus seeking and embraced its core principles in its policies:

- International goals as enshrined in the Millennium Declaration (particularly the Millennium Development Goals, MDGs), with a timeline to 2015.

- Financing targets for development (Monterrey) until 2015.

- Aid delivery modes, donor harmonisation and alignment (Paris Declaration) with a timeline to 2010.

At the latest around 2015, there will have to be a stock-taking of how far the aid system has come with the instruments defined in Paris and Monterrey to reach the MDGs. If substantial progress towards the MDGs can be demonstrated, they are likely to establish themselves as the development co-operation leitmotif even beyond 2015. But the closer to 2015 the donor community comes without being able to meet a substantial part of the goals, the more this consensus will come under pressure and will be challenged. There are two scenarios for failure. The first is that the policies were right but the money or the management were not forthcoming. The second is that the world and thinking about development has changed. Can European co-operation successfully manage persistent challenges in the area of international development in a changing global environment?

2. Newly emerging challenges to 2020

Beyond some global progress and persistent problems in meeting the goals on the international MDG agenda in many regions, new issues arise that will impact on global development:

- The importance of China, India and other emerging powers in the world economy and with respect to global economic growth will likely continue to increase. China and India's combined GDP is expected to account for more than 10 % of global wealth by 2020.

These *new actors in international development* include state as well as non-state actors – and just like the EU, they have an impact on development prospects of others, whether they like it or not. In some sectors, these emerging powers are out-competing economic actors from other

developing countries and their economic rise increases pressure on global resources.

- The linkage between various goals is often complex. *Energy security, democracy promotion and development*, for instance, come with considerable potential for contradictory agendas. When resources become scarce and energy needs are not decreasing, it might prove even more difficult to establish a coherent vision of balancing Europe's policy on energy security with the value-laden aspiration to foster democracy and development at the same time. Political commitments by the EU read well. Yet, self-interests might become less enlightened, after all, as the world is moving quickly and unprecedentedly into a situation of possible global energy shortages. This affects Europe and also other development actors.

- A number of global challenges may well lie beyond the framework for development, but are crucial to address in order to advance development prospects. Ecosystems are changing rapidly through human activities. Scarcity of resources, whether fresh water or arable land, in some regions is likely to increase. Environmental and consequently *developmental challenges resulting from climate change* will be significant. The countries least responsible for CO₂ emissions, such as the least developed countries, are in fact the most affected by climate change and will require – and demand – support to cope with consequences. Scenarios that go beyond the projected rise of global temperatures up to 2 or 3 degrees are more threatening and often described as the tipping point, the collapse of entire ecosystems representing one dire potential outcome.

In brief, the international system has come under pressure. The overarching question of EDC2020 is the role for development policy in the policy mix of the multilevel system of the European Union, explored in the three thematic areas outlined above.

Besides that, Some trends are actually 'good news' at global level:

-The number of the world's poor is declining, mostly in China and, to a lesser degree, in India.

- There has been progress in education in many parts of the world and overall, literacy is likely to increase for all regions by 2015.

- Global life expectancy is rising.

-World merchandise exports are increasing, not least due to the expansion of markets in East Asia, but also due to recent accelerating growth rates in many Sub-Saharan African countries.

- Net capital inflows have increased to developing countries, including Africa, even though inflows continue to be spread unevenly across the developing world.

However, these pieces of good news reflect global averages. Poverty in Sub-Saharan Africa and South Asia will remain a problem and vulnerable populations will be particularly hit by increasing food prices and the effects of climate change. Coping with malnutrition remains a major challenge in many places. Diseases like malaria, HIV/AIDS or tuberculosis represent threats to lives of poor people in developing countries and global warming might expand the area with Malaria prevalence. And the world's population is set to expand to around 7–8 billion people by 2020; almost all of this population growth will take place in the developing countries. In addition, globally more people are now living in cities than in rural areas: 2007 was a global turning point. These trends point to multiple development challenges in numerous locales.

3. Challenges for international development co-operation

When discussing future challenges to international development and how Europe addresses them in its external relations, two general questions are emerging which press all European donors for clear answers:

- *Which issues can and should be tackled by international development policy?* Is the specialisation / compartmentalisation of aid in external policies the solution or the problem? Should development co-operation focus on the poorest countries only? What does development policy's mandate and expertise embrace – and where should it end, leaving tasks to other experts in external relations? Shifts in various external agendas such as security or trade policy are likely to influence development co-operation prospects. Due to the difficulty in managing competing interests, however, policy

coherence for development remains a challenge.

- *Who does what? The question of the international aid architecture* Who should tackle which issues in international development? Or rather: with whom should we tackle them? More actors are entering the international arena, both state actors and private foundations, as well as an increasing number of global funds. The EU is one likely force for cohesion and donor coordination, but at the same time it is a factor in proliferation of donors. The EU continues to consist of 27+1, and future enlargements (Western Balkans, Turkey?) are likely to increase the numbers.

4. One set of goals and instruments for co-operation?

The delivery of aid can at best assist countries in mobilising their efforts to address challenges. Development cooperation should thus not be regarded as the one and only silver bullet to global problems. It is somewhat like providing risk capital: aid will work in some cases and not in others. And official development assistance (ODA) is, indeed, only a tiny fraction of global financial flows, additional to private capital flows. Developing countries are increasingly differentiating; some countries are new stars, others are starting from a completely different basis due to conflicts or failed government policies. Accordingly, donors will have to think how to differentiate goals and instruments in international co-operation. These vary across different types of countries (cf. Faust / Messner 2004), for instance:

- the poorest countries (Least Developed Countries, LDCs) with substantial capacity constraints;
- fragile or failed states, with de facto non-existent internal or external sovereignty;
- emerging powers (the 'BRICS' - Brazil, Russia, India, China and South Africa).

With regard to goals, discussions range between e.g. poverty reduction in the LDCs, establishing basic security in fragile / failed states, and jointly managing global governance with the emerging powers. Instruments also vary: from capacity building over nation building to co-operation on global issues. Hence, the policy mix towards

partner countries is necessarily different from country to country.

5. The EU in international development over the next decade

Since the beginning of the 21st century, Europe has embarked on a renewal of its development co-operation. The EU will now have to turn to new global issues and challenges in order to even just maintain its role in the world and to work for international development. The architecture of aid and modes of delivery in this fragmented system appear to be a problem.

The major argument surrounding the future of EU development co-operation actually stretches beyond the scope of development cooperation as a policy area: Europe can only increase its influence at international level if it stands together. Decisions taken now within the EU will impact on European development co-operation for the next decade or so. As one of the key decisions to be taken, the Lisbon Treaty offers a number of changes in the area of international relations that are bound to have repercussions on development co-operation. It will be important to retain a voice for development at the highest level of political decision-making. How will a possible European President position him- or herself in external relations? How will the not-so-called EU Foreign Minister fill the position? And how will development co-exist alongside or become integrated in European external policy making and possible institutional changes (namely: the External Actions Service)? Structures can facilitate or hinder certain debates – thus structures are important and solutions to the stalemate over the Lisbon Treaty will need to be sought. They will determine if the EU is capable to manage global challenges to 2020. Specialisation of agencies is one way to keep actors in and relevant. Specialisation can be on countries / regions or on specific topics or on both, as the EU Code of Conduct for a Division of Labour of 2007 has rightly concluded. Reforms will not necessarily have to result in centralisation in Brussels. It will be a key issue in the EU – and not an easy one – to make a better division of labour work amongst Member States and the

Union's institutions. This will be a crucial opportunity to reform the system from within and to achieve progress on better aid effectiveness, in order to avoid the risk of irrelevance. Emerging powers have a strong bias for bilateral cooperation, thus cooperation schemes with some of them will become even more important. But how can these actors effectively be engaged? Options range from 'business as usual' over coordination/harmonisation to a greater emphasis on multilateralism. Questions remain over the appropriate forum for dialogue with these emerging powers and other actors as well as with respect to what mechanisms should be used to enhance cooperation with them. The United Nations are important to obtain global legitimacy. They are thus one suitable forum to address issues of global public goods. Other setups, like the G8, are also pointing towards a potentially increasing role of the EU as a medium for European states to retain a meaningful role at the international level and to work for the protection and / or creation of global public goods. Europe will be expected to act; global impact comes with global responsibilities.

Morale and Ethics in Taxpayer Behaviour

Ștefura Gabriela

"Alexandru Ioan Cuza" University of Iași

gabi.stefura@gmail.com

Abstract

Taxpayer behaviour represents a subject of great interest for many research fields (economy, sociology, psychology etc.) and the studies that have been made until now have emphasized its importance and its complexity.

This article creates a theoretical frame around two important factors of influence of the taxpayer behaviour that have been studied in the speciality literature, the morale and ethics of taxpayers.

The majority of the studies have shown that morale and ethics have an important influence on the tax compliance behaviour, and their analysis still represents a strategic point in understanding this type of behaviour.

Key words: taxpayer behaviour, morale, ethics, compliance.

J.E.L. classification: M31.

1. Introduction

On the basis of decisions that individuals make in their purchasing process (in this case, the process of making payments to the state), is the need. An urgent need that is causing the individual to take measures to reduce or virtually eliminate the tension caused by the need to satisfy that need. Thus, each person or company needs an incentive to make expenditures.

Of course, the motivation may be very different depending on the needs felt by the individual. Basic needs, food, clothing etc. will always stand above the rest (in some cases). However, the state debt, taxes and fees can not be classified as needs, but can be included in the category of social obligations. As long as the individuals live in society and use the services it offers to them, they must fulfil their tax obligations to ensure the proper functioning of the economy, and

hence of the society.

The analysis of the behaviour of individuals in relation to the payment of taxes and fees cover both items related to the description of the process and factors that can influence this behaviour. Because the behaviour that people are somehow forced to adopt is brought into discussion, at a first analysis, things appear to be easy to understand, but as we get into the depth of the subject, the details are much more varied and complex than they seem at first sight.

This article aims to create a theoretical introduction in explaining taxpayer behaviour and two of the most important factors to influence it.

In the second part of the article, the behaviour of taxpayers it is briefly described, along with influencing factors and in part three the discussion focuses on tax morale and ethics, two crucial concepts in studying this topic.

2. Taxpayer behaviour and its influences

Most theories that have tried, in a lesser or greater extent, to explain the behaviour of individual taxpayers have focused on describing the tax compliance behaviour.

Compliance with the payment of taxes is the voluntary submission to the rules and laws of the tax system in order to contribute to overall economic welfare.

Taxpayer behaviour occurs depending on the action of factors which come from the external or internal environment. The internal environment factors are essentially psychological factors acting within the taxpayer, are those closest to him, and therefore the most sensitive.

The factors from the external environment refer to the state and its actions in the tax

system, economic opportunities, reference groups etc.

Each influencing factor is important and cannot be left aside, but there must be made a differentiation between them, to better understand each one.

Alm and McKee make a listing of key factors influencing tax compliance, in one of their papers [1, p. 264]:

- Audits and audit selection rules;
- Punishment;
- Perception of fairness;
- Overweighting of low probabilities;
- Fiscal uncertainty and complexity;
- The burden of compliance;
- Government services;
- Fiscal institutions and political decisions rules;
- Social norms;
- Reputational effects;
- Tax amnesties.

The diversity and complexity of all factors emphasizes the importance of studying tax compliance. In most of the studies that have been made, tax morale and ethics stand as two of the most important factors of influence.

3. Morale and ethics. Influences on taxpayer behaviour

In several studies, tax compliance is associated with concepts of "tax morale" or "tax ethics."

Morale in general is the ability of people to have confidence in an institution in a particular purpose, or even in themselves. Ho and Wong believe that morale represents a system of rules of conduct that are meant to guide behaviour in social or interpersonal manner [6].

The concept of morale in terms of taxes and duties relate to the individual's intrinsic desire to pay taxes [2] or actually measures individual attitudes towards the tax system. Another definition shapes tax morale as "a moral obligation to pay taxes, moral faith in contributing to the society" [12, p. 444].

The concept has been previously studied in detail by the School of Psychology from Cologne [2].

Torgler believes that tax morale may be the answer to several questions related to the behaviour of taxpayers [10].

Dell'Anno studies taxpayers' morale with the help of two of its components [4]: moral rules (which refer to the psychological cost felt by the taxpayers) and social stigma (the cost of the reputation). The author has shown that when the social stigma increases, also the degree of compliance of taxpayers increases. Besides this phenomenon, the social stigma is positively influenced if people perceive the behaviour of the government as fair and effective.

Tax morale is modelled also as a internalized social norm of compliance. Traxler thinks that, when taxpayers declare only a part of their income, they overlook the social norm, and in the end tax morale [14].

Ethics is based on a branch of philosophy that seeks to address questions about morality. For centuries it has been the attention of philosophers the antithesis between good and evil and how people can live by doing what is right. Ethics is defined as being a belief system that supports a particular vision of morality and involves research on the tendency of doing right or wrong [6].

Often the concepts of morale and ethics are used as synonyms, although they are different in their nature by what they are trying to explain.

Tax ethics refers to the belief that is a moral imperative to be honest in the conduct of paying taxes [14]. Alm and Torgler perceive it as a set of moral principles or values that taxpayers hold [2].

The probability that an individual does not behave ethically as taxpayer depends on [6, p. 370]:

- The gain expected from this behaviour;
- The perception of the chance of being caught;
- Attitude towards risk;
- The level of ethical thinking.

In studying the behaviour of taxpayers, the notions of "morale" and "ethics" are often analyzed in the same context. Their introduction in this field of study is somewhat in contrast with the approach of taxpayers as rational actors pursuing the maximization of personal gain [15].

Wenzel discusses about a "personal" ethics of the taxpayers, saying it can be almost one of the best predictors of tax compliance [16]. Also Wenzel, but in another

article, has shown that ethics has a significant influence on tax compliance, and vice versa, compliance can influence tax ethics [15].

Blanthorne and Kaplan propose a new model for the study of compliance, which concentrates on the taxpayers' ethical beliefs on tax evasion and highlight the fact that they occur independently of economic considerations, but are influenced by the opportunity of the taxpayers to avoid paying their taxes [3]. In their opinion, the opportunity to avoid paying taxes influences the formation of ethical beliefs of individuals about tax evasion and the beliefs, in turn, influence the compliance behaviour, a fact which has been previously analysed by Reckers, Sanders and Roark [8]. Therewith, ethical beliefs will have less influence on people already prone to tax evasion.

Morale is brought into discussion also when considering the relationship with the authorities. It is closely related to the confidence of taxpayers in fiscal institutions, in the government etc. [2]. The link created between taxpayers and authorities is regarded as the "centre of gravity" of the individual tax morale [5].

Torgler and Schneider believe that the positive actions of the state grow in a positive way the attitude and commitment of taxpayers to the tax system. On the contrary, if the state is perceived as being unfair, this increases people's willingness to act against the system [12].

Schmölders thinks that the basis of successful taxation is the development of a civic sense and a minimum of commitment from taxpayers [9]. The same author points out that sense of taxation and the awareness of the tax burden have a direct impact on tax morale.

Another study analyzes the importance of local authority relations with the taxpayers, with an emphasis on decentralization and its connection with the morale of taxpayers [13]. According to the authors, decentralization allows a better connection at the local level with people. Thus, they demonstrated that there is a strong positive correlation between local autonomy and tax morale. The trust in the state's institutions, even locally, is again highlighted as a stimulating factor of morale; the more the confidence grows, the more taxpayers' morale grows.

Among the factors of influence of tax morale are socio-demographic characteristics, personal financial experience (income level, employed or self-employed, etc.) and political attitudes (satisfaction with democracy, trust in politicians, measures to reduce differences in income) [7]. Morale is positively correlated with age, religion, income, satisfaction with democracy and trust in politicians, and negatively with education and employment status. The same study revealed that people who live in wealthier regions are less likely to comply to the payment of taxes because, by redistributing state revenue to poorer areas, those in wealthy areas tend to see redistribution such as incorrect and to refuse or avoid paying taxes.

Torgler adds a new contribution by making a connection between tax morale and religiosity [11]. The more religious the taxpayers are, the higher the degree of tax morale is. Effects of correlation between morale and religiosity are highly visible to those who have benefited from a strong religious education or those who engage in church-related activities. Catholics, Hindus, Buddhists and those with other faiths have shown a higher morale, while Orthodox and Protestants have shown a lower tax morale.

People that see the tax issue as a moral goal will present a greater degree of tax compliance [8].

However, there are some contradictions in the speciality literature. Schmölders asserts, moreover, that studies made by psychologists have shown that the obligation to pay taxes has very little to do with the moral part of human consciousness [9].

4. Conclusions

Even though morale and ethics seem not to be related to the issue of taxpaying, they are two very important factors of influence of this behaviour.

Different studies have demonstrated that a positive relation is formed between tax morale (or ethics) and tax compliance. Therefore, a taxpayer with high tax morale will also have a high degree of compliance in relation with the taxes or the tax system.

The importance of studying tax morale and ethics derives from complexity of the human being and the many behavioural characteristics he/she shows. Another direction comes from the institutional point of view. Although paying taxes comes as a social obligation and the process can be very simple, those interested in the subject should enter in the depth of the issue, in order to better understand it.

The issues presented in this paper may be useful to both theorists and practitioners, especially those directly interested in the field of taxpayer behaviour. Also, the information offered may offer a good research starting point and also some insight to the fiscal authorities.

As further directions of research, an analysis on the morale of more specific categories of taxpayers or maybe on the connection of morale with the cultural setting would be useful to the taxpayer behaviour literature.

Tax Compliance Behaviour

Ștefura Gabriela

"Alexandru Ioan Cuza" University of Iași

gabi.stefura@gmail.com

Abstract

To every state it is essential to ensure that the public budget copes with the public expenditure, in other words, to make sure that it collects sufficient revenues in order to have a stable economy. These revenues come especially from the collecting of taxes and fees.

In order to have a functional fiscal system, it is important to understand both the fiscal component and the behaviour of its contributors. That is why the taxpayer behaviour has grown as a subject of research, in many fields besides economy (psychology, sociology etc.).

In the specialty literature, taxpayer behaviour has perceived as the compliance behaviour of taxpayers, in relation with the declaration and/or payment of the income tax. The main conclusion draws attention to the complexity and importance of this behaviour, to both theoreticians and authorities.

Key words: Taxpayer, compliance behaviour, income tax.

J.E.L. classification: M31

1. Introduction

The subject of tax payment is one of major concern especially for economists and became the focus for numerous studies over time. But studying the fiscal phenomenon cannot be complete without entering into the analysis of both parties involved in the collection process, the tax component and the human component, those who contribute by paying taxes and duties. The second direction, the analysis of taxpayers, has been addressed in order to broaden the spectrum of specialist knowledge and can improve the tax component when necessary.

Analyzed from various perspectives, the component related to taxpayers brings its contribution specifically by trying to describe their behaviour in relation to the tax system, which could be a topic of interest to many disciplines, not just the economy.

Globally, it is known the so-called "tax aversion" of people [13], and as the taxes are more numerous and larger, the general aversion is growing. This aversion is emerging as the dissatisfaction created by the duty of paying taxes. In Romania, this aversion may reach very large proportions, being one of the countries with most taxes.

Taxpayers' behaviour is captured in the specialty literature under the form of tax compliance behaviour.

The purpose of this paper is to make a theoretical "portrait" of the concept of individual taxpayer compliance. In the next part, the concept is defined and the third part the dimensions of compliance are described, as found in the specialty literature.

2. The concept of tax compliance

Compliance, in general, refers to the act of subordination, obedience to rules, desires, activities, laws, even if they are not welcome or wanted. This subordination is not forced, however, individuals act voluntarily, even if they do not feel particularly drawn to that direction.

Tax compliance behaviour has been extensively studied in economics literature, but its importance has grown especially in the last 10-15 years, when, in fact, the consumer, generally, has become one of the most important topics of study.

Compliance with the payment of taxes could be defined as the voluntary obedience to the rules and laws of the tax system in order to contribute to overall economic welfare. However, it might be associated with the idea of fulfilling the role of the consumer-citizen within a state. By

complying, the consumer-citizen contributes to the public budget by paying taxes and fees and, on the other hand, he uses public services (health, education, etc.), funded by these contributions precisely.

Figure 1: The relationship between contributors and the public budget

Kirchler and Wahl [10, p. 333] consider that compliance is the most neutral and inclusive term that describes people's willingness to pay taxes.

3. The dimensions of tax compliance

Compliance was first studied more in psychology. Then, sociologists began to be interested in the analysis of taxpayer compliance behaviour, transforming the area into one interdisciplinary study. Wentworth and Rickel [15] believe that the common trunk of the early studies consisted of an analysis of attitudinal and psychological variables, joined later by the sanctions from the state.

Regarding the various approaches in the literature, most scholars have chosen the direction of compliance behaviour analysis in relation to income tax. This topic has gained importance also due to the American specialists, whom have a very solid research base because the U.S. income tax system is extremely important and the rules are more stringent than in many European countries. But also the interest in data collection about taxpayer behaviour, in various forms, was higher.

However, the study of tax compliance behaviour has gained considerable proportions worldwide, in the past years, by the implementation of various comparative studies between countries on different continents, relating them or not to the

behaviour of American taxpayers [9; 11; 12].

The view that dominates the speciality literature captures compliance as a function of the rational pursuit of self-interest contributors [16]. From this perspective, taxes are costs that taxpayers seek to avoid or reduce them.

The main direction in the economic literature on compliance has been drawn by Allingham and Sandmo, in 1972 [1], in an earlier study that continues to be the starting point for many other research studies. According to their theory, taxpayers are faced with a choice: declare their income entirely or less. In their model, the authors were concerned primarily, if higher levels of tax increase or decrease the level of compliance. However, the assumptions made by Allingham and Sandmo are based on standard microeconomic concepts, such as: individuals seek to maximize the utility of their actions, the utility increases as the wealth grows etc.

The Allingham-Sandmo model is based on a simple function of expected utility. The decision to pay or not taxes relies on the likelihood of being caught and the fine taxpayers could receive if they are caught by the authorities. If penalties are proportional to the size of avoided taxes, then the model could predict that evasion is reduced when the level of taxation increases. But this model only focuses on the income tax, and other authors have extended this model for other types of taxes, adding the risk aversion to the influences of compliance, but also how it can be treated subject in relation with neuroeconomics (an interdisciplinary field that seeks to explain human decision making, the ability to process multiple alternatives and to choose an optimal course of action. It studies how economic behaviour can shape our understanding of the brain, and how neuroscientific discoveries can constrain and guide models of economics) [5].

Yitzhaki [17] continued development Allingham-Sandmo model by highlighting the fact that the penalties, in most tax systems, are not calculated according to the size of undeclared income, but rather to the amount of unpaid taxes. Other studies took into account other variables such as:

introducing a more robust tax structure, expanding the number of items that the taxpayer should report, the role of morale etc.

Alm et al. [2] make some criticism regarding the classical Allingham-Sandmo model. Thus, they believe, on the one hand, this model addresses decision to declare. On the other hand, traditional models assume that people know, with certainty, the true tax liability; in reality, a country's tax code can be quite complex, leaving enough room for interpretation. Chorvat [5] also sustains the "simplicity" of these models, but points out an important feature of standard economic models: people feel a large aversion to penalties.

Ashby et al. [3] make some observations about the individualistic vision of education as that of Allingham and Sandmo, considering that the payers of taxes and duties have been characterized as pursuing their own interest to maximize utility, so they avoid paying taxes out of pure greed, this being a relatively small view in the opinion of the authors.

Torgler [14] sees compliance as a function of opportunity, tax level, the likelihood of being caught, also the individual's willingness to comply or to avoid paying taxes.

Taxpayers are viewed from multiple perspectives, and one of them refers to the differentiation between them, based on compliance [10, p. 334-335]:

- Compliance by commitment (people pay their taxes willingly, without complaint);
- Compliance by capitulation (people who started the uprising, but eventually give in and pay their taxes);
- Resistance to compliance (a negative attitude towards tax authorities);
- Disengagement (keeping a social distance);
- Game playing (taxpayers view their behaviour and the relation with the authorities as a game).

Torgler [14, p. 124-125] brings into discussion four types of taxpayers:

- Social taxpayer (who is influenced by social norms, feels guilty when reported as actual, is influenced by what happens around him, so if others pay their taxes, tends to do the same);

- Intrinsic taxpayer (for him, the motivation includes the sense of obligation, is sensitive to institutional factors, so the way people are treated by the authorities represents another factor for him; he has an internal motivation to pay taxes);
- Honest taxpayer (does not avoid the payment of taxes, in any circumstances);
- Tax evader.

Another classification of taxpayers divides them into [7]: honest, susceptible or evaders.

Carroll [4] differentiates taxpayers by way of choosing strategies to pay taxes or avoid them and by the way they address the issue of taxes (they show interest from the beginning or leave everything to the last moment). Strategies may be high-level (involving a good plan in place: looking for information, registration of information, keeping records, etc.) or low-level (copying someone else's statement, less the amounts). The author points out that tax avoidance can be planned in advance.

Compliance cannot be brought into discussion without taking in account its opposite, non-compliance. It represents the process of paying fewer taxes than it should be done, in other words, the taxpayers' attempt to avoid their tax obligations in their entirety.

From the analysis of the specialty literature, two forms of non-compliance result: tax avoidance and tax evasion. Avoiding taxes by legal forms is subject to the law, unlike tax evasion which is illegal. Avoidance may mean paying a minimum amount, taking advantage of a time when authorities plan to increase certain fees and purchasing products before the increasement etc. Evasion represents the taxpayers' refusal to pay taxes.

Compliance may be, in turn, voluntary (in the case of honest taxpayers, who know their role in society) or forced (when authorities through various forms of taxation, oblige taxpayers to pay, even if this is not their wish).

Figure 2: Compliance and non-compliance

Kirchler and Wahl [10], in their study, emphasize that voluntary compliance and forced compliance cannot be correlated, but between voluntary compliance and non-compliance may be drawn a negative relationship. However, they also demonstrate by analysis that there is no correlation between the two types of compliance.

An interesting perspective on compliance is provided by Feld and Frey [8], who see compliance as a "psychological contract" between taxpayers and the government. This fictional agreement, however, works about the same as a real one (the provision of services, for example), the taxpayer must pay taxes in order to benefit from public services and the state should support contract with incentives (bonuses or penalties).

In the opinion of the authors, the concept of a contract between the state and taxpayers has more advantages than other concepts of the traditional theory [8, p. 106-107]:

- Works on the idea that paying taxes is a semi-voluntary act;
- Stresses the role of fair procedures;
- How taxpayers are treated is a very important point taken in account.

The way how taxpayers are treated is divided into two parts. The first relates to procedures and that they must be "transparent" and clear. The second focuses on the respecting taxpayers, a dimension that has a more personal connection, by focusing on respecting their personality (treating them as full partners).

The concept of contract has been approached by other authors in advance. For example, Riah-Belkaoui [12] analyzed the concept of "social contract". The social contract concerns, as the psychological one, the exchange between the state and the people. The author emphasizes that it is a special contract under which the taxpayer

trusts the government and complies in bearing the tax burden in certain circumstances, by what the government gives back [12, p. 137]:

- Effective competition laws;
- High economic freedom;
- An important role accorded to the equity market;
- Moral norms.

Carroll [4] sees the payment of taxes as a sequence of decisions and actions that involve economic transactions, record-keeping and completing statements. He also believes that in the case of taxpayers, the theory that they adopt certain strategies in the decision making on taxes and fees, is applicable (whether to hire an accountant, whether to keep certain records, etc.). People, in his opinion, focus on two approaches that define the choice they will make: norm-processing rules (what they should do) and outcome-processing results (which direction will bring the most benefits).

Although the traditional economic theories rely on the idea of rational human behaviour, especially in the case of taxpayer behaviour, as in the case of general behaviour, these theories can not be applied. Human behaviour is too complex to be only rational. In particular, given the many tax forms available, the observed degree of compliance with the payment of taxes can not be related to a purely rational economic behaviour [6].

4. Conclusions

Tax compliance is a very complex and important field of study, due to the importance of understanding how taxpayers act in relation with the process of declaring and payment of taxes.

No matter what methods of research the specialists use, the main difficulty rises from the wish of obtaining reliable data. As the subject, from the taxpayer's perspective, is a sensitive one, the sincerity of the answers may be questionable and that is one of the weak points in this research.

The different approaches on tax compliance have, mainly, the same conclusion: taxpayers are either compliant or

noncompliant. But the reasons of choosing one of these directions are in the attention of most researchers.

As future directions of research, a closer look on the typology of taxpayers may give interesting results or even a more detailed approach on the concept of "social contract".

Linguistic and Cultural Interferences in Translating Economic Texts by Means of Borrowing Words from the Source Language-Culture

Tamas Cristina

„Ovidius” University of Constanta

cristina_tamas2003@yahoo.com

Abstract

Within the present social, economic, and political context, we have increasingly become translation consumers. At the same time, any translation refers to certain national cultures, thus revealing the specificity and the identity of each language. In this respect, a translation should be considered as a work of re-creation, with its strengths and weaknesses. A translator's activity is creative beyond theory, as they rebuild an edifice without using architectural skills.

Key words: specialized translation, borrowed words, source language-culture, target language-culture

J.E.L. classification: ZOO

A translation, may it be literary or specialized, is often partial, since it is defined by a certain degree of entropy, as any communication act is. Therefore, a translation becomes practically synonymous with loss of information. Thus, a translator should permanently distinguish between what is essential and what is mere appendage and take into account the outcome of the translation act, which should always be oriented towards the target public, as far as its cultural awareness and its familiarity degree with the text being translated and the source language are concerned.

The cultural component of translation is defined in terms of competences with a view to creating a homogeneity between linguistic level (where a complex of competences is involved, i.e. interactional, comprehension, discursive, textual, lexical competences) and cultural dimensions (i.e. knowledge and education).

Thus, a translation may sometimes aim at obtaining local colour, and then, according to G. Mounin, "the translator's spectacles will have either coloured glass or transparent glass" [1]. Following the developments achieved in the fields of information and technology, both teachers and students of a foreign language need to adapt and deliberately resort to various learning methods in which translation is involved, in order to cope with everyday life requirements defined by "speed" and performance.

Faced with a lexical gap in the target language (a word difficult to translate), the translator can proceed in two ways. He can either resort to the desperate solution of borrowing by barely importing the foreign source word as such (*signifié* and *significant*) or use a calque (a borrowing of the *signifié* into the *significant*). One can also approach the semantic aspect of textuality (textual coherence based on relationships pre-existent in the reality that it reproduces). It is also worth mentioning the problem of referential and intratextual relationships, and the one of retrospective (*anaphora*) and prospective (*cataphora*) categories.

For example, the word *best-seller* has become an expression used in French to the same extent as in Romanian. If we want to literally translate this compound word, we should not say *best-sellers*, but *cele mai vândute, les plus vendus* respectively, nevertheless a translator will undoubtedly use the English compound word, since it is already and frequently used by everybody.

Similarly, the word *mass media* is used in French with a minor spelling variation - a sharp accent and a final *s*: *medias*. Given the fact that *medias* is the plural of the Latin word *medium* – *mediu*, the spelling without an accent (Latin does not use accents) and without a final *s* becomes possible, since *media* is a form of plural. Consequently, the spelling *masse-médias* (with *e* at the end of

the word *mass* and a hyphen) is possible and does occur in French.

Mass medias, a phrase that originates from American English, is used with reference to mass media such as radio, television, printed press, books, cinema, advertising. Specialists in the field of translation theory acknowledge that the phrase *mass media* is not the most appropriate one since it does not necessarily include an exchange of ideas, and that *mass spreading* should rather be used in this respect. For this reason, they still hesitate to include the word *telephone* in the same category among other media. The same holds valid for *Minitel* which provides the requested information only and which may be at the origin of some quality information exchanges.

In both cases, both the word and its referent are imported from the source language-culture. The borrowing may add stylistic value in terms of "local colour": in French as a target language, *feed-back* may prevail over his belated counter-part *retroaction*. [2].

Another means of translating texts is the literal, word for word translation which resembles the trans-coding.

Besides these three "direct" solutions, J. Darbelnet and J.P. Vinay suggest four procedures of "oblique translation".

Transposition replaces a "part of discourse" with another: thus, where French uses the verb *aimer* (*aimer se baigner*, *aimer le chocolat...*), the translator will often make up a modalized sentence. [2]

Modalization involves the replacement of a synonymic expression, the same idea being rendered differently in the source language and the target language: the English *forget it* becomes in French *n'y pensez plus*.

Equivalence considers the source-statement as a whole and suggests a target-equivalent which corresponds to the same non-linguistic referential situation. Therefore, the French *j'ai une faim de loup* will become in Spanish *tengo un hambre canina*.

Adaptation merely designates a translation method, but rather a source-message which does not exist in the target-culture. In the biblical language, translation proves to be difficult sometimes when various parables are involved (such as that of the fig tree, which does not exist as a word in the languages that do not designate this tree).

In this category we can include two frequently used terms, i.e. *interprétation* and *interprétariat*. [3] Regarding the first term, D. Seleskovitch mentions that: "We currently use the term *interpretation*. It's a more 'trendy' Anglicism; moreover, it is a more or less known label change (as we can see in all professional media). *Interprétariat* rhymes with *secrétariat*. At present, *interprétation* designates a conference interpreter's job, whereas *interprétariat* refers to subordinate (and in general preliminary) 'contact' tasks" [2].

A special emphasis should be placed on the fact that adaptation uses the same translation mechanisms; first of all, the analysis of the complex lexical meanings and the consideration of its specific socio-cultural load (civilization component, language level, socio-cultural allusions). [4] Translation is made afterwards through the intermediary of the intensity degree rendered by the intensifier in functional interconnection with the basic term.

"The variety of pertinent information needed in order to properly translate a sentence depends on the functional relations and the semantic and referential properties of the constituents involved in the sentence construction". [5]

The next step is represented by choosing the appropriate equivalent, with the recovery, at least partial, of the peri-linguistic load by means of compensation techniques.

Sometimes, this type of translation can be seen as a linguistic oddness since these associations should be rendered within an intra-linguistic communication in which the metaphor that contributes to information flow has also a psycholinguistic function. What should be done, for example, with a newspaper feature that contains an allusion within a phrase?

"*Mais la journée de vendredi a montré qu'au sud des Pyrénées il était imprudent de vendre prématurément la peau de l'ours*". It should be mentioned from the beginning that the adverb *prématurément* is unnecessary, because *vendre la peau de l'ours* means an action which is taken in advance. On the other hand, the question may arise: Should the translator simply use the Romanian equivalent or should he search for an expression which could render the text's idea in a journalistic way? In fact, this phrase has

already become famous and originates from La Fontaine's fable "*L'Ours et les deux compagnons*".

The story of the fable says that two companions were selling the skin of a bear which they had not killed yet, but which they were going to kill very soon, in their opinion. When they meet the bear, they get scared; one of them climbs up a tree, while the other pretends to be dead. The bear whispers in the pretended dead body's ear: "*You should never sell the skin of the bear which you couldn't lay down*" [6].

When reading the expression *you should never sell the skin of the bear* (without being necessary to add *before having it killed*), one usually understands the allusion to the danger of committing a sin through false optimism. Consequently, there are several options for translating this part:

- a) a literal translation through the use of the same adverb *prématurément*: *However, Friday proved that in the south of the Pyrenees it was imprudently to sell the bear skin in advance.*
- b) a translation through modulation: *to sell in advance was an imprudence.*

Such phrases are being used nowadays by the media and, unless they are properly understood with all the references they imply, a complete understanding of the text is almost impossible. Two further examples are given, as follows: „*Les Polonais qui ont vu ces subventions gouvernementales se réduire comme une peau de chagrin sans bénéficier d'un meilleur approvisionnement des magasins d'Etat, se débattent encore*". [6]

The term *chagrin* has nothing to do with *emotional pain* or *sorrow*, since here the real meaning is that of a sort of leather. *Chagrin* is in that specific context "a granulated leather, originating from the East, which is obtained from the skin of various animals (donkey, goat, horse, shark), and which is used especially in the field of bookbinding".

The phrase *réduire comme une peau de chagrin* is actually inferred from Balzac's novel *La Peau de chagrin* (1831). The main character in the novel, Raphael de Valentin, has in his possession a magical piece of *sagri* leather, that is shrinking every time when fulfilling a wish of its possessor, whose life would become thus complicated and confused. Balzac infers the idea that an

intense life could only be a short life, as if everybody would dispose of a certain amount of vital force to spend.

Therefore, the phrase *peau de chagrin* renders the idea of contraction, narrowing, or reduction. We can always describe for instance the powers of a politician as shrinking as "a piece of *sagri* leather". The same idea is retained by the above-mentioned text: the granted subsidies are unrelentingly being reduced in the way the piece of leather from the Balzac's novel shrank.

The second example can be included in the language of both politics and journalism.

„*En choisissant M. Uno, les caciques du parti libéral ont fourni une preuve éclatante de leur refus de nettoyer les écuries d'Augias de la vie publique, de tirer un trait sur des pratiques qui ont achevé de déconsidérer leurs chefs de clan...* ». [6]

The phrase *nettoyer les écuries d'Augias* originates from the 12 labours that Heracles, the greatest of the Greek heroes. The labours were almost impossible to perform and have been assigned to Heracles as a penance for killing his wife and children after a madness crisis. The fifth labour consisted in cleaning the vast Augean stables in a single day. Heracles succeeded by rerouting two rivers to wash out the filth.

Therefore, the allusion to Augean stables is being made when a re-establishment of order, especially a moral cleansing, within an organization is needed, as the case is in the above-mentioned text.

A list of words that also exist in Romanian language can be included in the same category of loans. A first example would be the adjective *itératif*, mostly used in the field of medicine, which refers to a repetitive occurrence.

A further example is the word *périodique*, which originally and scientifically designated "the periodical movement of a pendulum", implying the idea of recurrence. The word transgressed to the common language to describe an event that occurs more or less regularly. In Romanian, the translation *periodic* bears the same meaning as in French.

The Romanian word *bilateral* originates from the French word *bilatéral*, mostly used with *accord*. In French, and in Romanian too, *un accord bilatéral* is an agreement between two sides (signalized by the prefix *bi-*). It

opposes a „unilateral” decision (taken by one side only), as well as a ”multilateral” agreement (completed between more signatories).

Another approach is the one that regards English words whose correspondents in French are being used in Romanian both in their French and in their English version. We have already mentioned that the commutation is not always possible, although specific synonyms or phrases do exist in French. The above-mentioned list of words can be extended with further examples. Chances are, for instance, that *penalty* cannot be replaced by „coup de pied de réparation”, whereas in Romanian we find the correspondent *penalti*. Similarly, *juke-box* does not become, as one scholar once wished, „tourne-disque a sons”. Moreover, against all attempts, the word *parking* resists as such in both Romanian and French.

A certain number of words are being used according to the linguists’ suggestions, but this is the case of a relatively reduced number of borrowed words. For example, the French word *ingénierie* seems to have succeeded in replacing the English word *engineering*, with the meaning of ”a global study of a project, conducted by a specialized office”. Engineering implies studying the many types of project impact by various teams of specialists, whose work will be consequently included in certain syntheses.

A special category of words that should be carefully considered are the (false) twin words, where the distinction between the two is carried by so few elements that confusion easily occurs. Thus, *induire* (to deceive) should not be confused with *enduire* (to paint a wall), as well as *coasser* (the loud calls of frogs) should not be confused with *croasser* (crow calls, croaking). There are many word couples in French, that distinguish themselves through one letter only. For example, the couple *conjecture-conjoncture*. *Une conjecture* means an opinion solely founded on suppositions and is mostly used when referring to the future as a space of probabilities. *La conjoncture* designates the entire phenomena describing a certain situation. Phrases like „en raison de la conjoncture”, „pour tenir compte de la conjoncture” are often heard in French. DEX (the Explanatory Dictionary of Romanian Language) emphasizes the fact that

Romanian language has borrowed both words from French: *conjectura* (trans. verb) = to judge from appearances, whilst the second word became *conjunctură, conjuncturi* = the complex of characteristics defining a certain moment in the process of economic development. [7]

Another problematic couple of words is the pair *précepteur / percepteur*. The word *précepteur* designates a specific office held by a person who levies taxes and revenues, while *percepteur* is a synonym for *prédateur*, i.e. beast of prey, predator. The term *précepteur* also designates a private teacher hired by a family to teach their children. These two words also exist in Romanian, *preceptor* (masc. noun) designates the person hired to educate and teach private lessons to a child (within a wealthy family), and *perceptor* (archaism) indicated a clerk who collected taxes and revenues. [7]

An example among economic terms is given by the word *exode*. *L'exode* stands for a massive emmigration, and is often mistaken for *exorde*, that actually means the beginning of a speech. An influence of the word « desordre » may be possible here, because an exodus is often synonym with a sort of haste and disorder. *L'exode* is also metaphorically used in the language of finance: *l'exode de capital*.

Finding correspondents for the various types of retribution is also problematic because of the terminology fluctuation, especially in the language of economy, which complicates the translation. For example, *salaire*, the Romanian *salariu*, is being used for workers and labourers only. For other categories, other words equivalent to the word *venituri* occur, even though the translation into Romanian does not cover all meanings. In French, the clerks’ income is called *traitement*, while artists and performers receive a *cachet*. Medical doctors receive *honoraires*, but that applies especially to freelance physicians. An MD who owns a consultation room receives *honoraires*. The term also exists in Romanian, *onorariu*, and designates the payment for services offered by an intellectual (freelance lawyer, medical doctor, etc.). [7]

Another word with various synonyms is *gages*, that means the salary received by a servant. The play *Don Juan* ends with

Sganarelle's amusing lamentation „Mes gages! Mes gages !”, as he realises his would lose his master, the one who provided for him. The word is still being used in some circles, but with a rather negative connotation, whereas *salaire* seems to prevail, as servants are assimilated to workers. The Romanian word *gaj* bears the meaning of a security deposit against a debt, and it usually implies objects or goods. [7]

An expert receives *vacations*, a word that is being used in connection with ministerial clerks, which confirms the terminology fluctuation once again. The amount of a *vacation* depends on the clerk's competence level and the task complexity. Similarly, whereas freelance journalists receive a *pige*, so they become *pigiste*, and are getting paid *à la pige*, i.e. in accordance with their published work. Journalists attached to a certain newspaper receive a *salaire*, whereas those affiliated to a public journal receive *traitement*. The words *vacation* and *pige* have no correspondents in Romanian.

Therefore, in order to accurately respect the meaning of the original text, translators should often "borrow" words from the source language and simultaneously distinguish between easily mistakable words. Translators' main task merely consists in finding equivalents, but rather in enriching their own language, not only by lexically mastering the translation process, but especially by considering the whole system of thought that both source and target languages imply.

Abstract

Starting with the half of the XIXth century, the labour force migration from the disadvantaged areas towards other states, more developed, can be seen as a mass phenomenon, where people wanted, overall, a better life. The labour-importing countries offered, at least at a conceptual level, a high quality life, from all points of view: socially, culturally, politically, and last but not least economically. Those who couldn't benefit of the advantages of emigrating into another state were the ordinary citizen of the socialist states from that period, which didn't have the right to leave the country of origin but in special conditions, and then, usually, the exits were allowed in general in the socialist, neighbour countries.

Nowadays, beside the more pronounced interdependence tendency of the world states and the liberalization of the borders, we can consider the brain drain phenomenon as a natural consequence of a more grasping globalization.

Key words: migration, labour force, brain drain

J.E.L classification: F22

1. The birth and development of the "brain drain" phenomenon

Skilled migration is a major trend among current migration patterns, being fuelled by the development of knowledge economies and by the emergence of a global labour market for skilled professionals. Brain drain is therefore a major concern for the international community, and there is a need to innovatively think about the way in which people's aspiration toward mobility and

migration can be reconciled with states' right to development.[1]

The "Brain Drain" term was used for the first time at the Royal Society of London to describe the emigration of scientists and people of culture towards USA and Canada at the beginning of 1950. The brain drain is the migration's component with high and very high degree of qualification in the field it activates in.

The "human capital flight" represents the emigration phenomenon of the educated or talented persons due to various reasons: social or political conflicts, lack of opportunities, etc. The investment in education is lost once the person leaves into another state, that person having relatively small chances of ever returning into the country of origin. [2] In this context it is difficult to realise a statistical report regarding the migration share of the labour force with a high level of qualification, reported to the entire labour force movement, because in the statistical reports the training or high training of the respective labour force isn't taken into account. [3]

The drain is expressed freely, it is limited, or at least it should be, by the countries of origin and encouraged by the receiving countries. Depending on the perspective, the term was translated in different ways in Romanian, by different authors such as: "scurgerea creierelor", "migrația creierelor", "furt inteligent", "racolare de cadre", "exod de competențe", "hemoragia creierelor" (that is brain drain, brains migration, intelligent theft, specialists recruitment, skill drain, brain haemorrhage,) etc. [4] All these interpretations are made under the influence of the countries which are only "brain suppliers", and underline only the negative part of the phenomenon. But there are optimistic approaches as well., obviously from the receiving countries, which name the

highly trained persons, at a general level, as being specialists and associates the term "brain drain" with „capital flight”.

Specialized labour force migration is practiced nowadays in the entire world, phenomenon specific to the capitalism, which, inside a real market economy, offers the possibility to the strong ones to become even stronger through the development of the quaternary sector represented by the top scientific research. For this purpose, USA, can constitute a perfect example in terms of variety of the populations and ethnic groups that live on its territory, through the fact that occupies the first place in the world classification regarding the sums assigned for top research development and inovation.

The emigration phenomenon of the great personalities, of the great scientists has an old history, starting from the antiquity: Thales (624 – 547 BC) mathematician, astronomer, philosopher migrated towards the Asian area to continue his studies and to study thoroughly his fields of interest; Pythagoras (582 – 507 BC) mathematician, philosopher, astronomer, left Samos (Asia) and arrived in South Italy, Crotona, to escape Polycrate’s leadership, also called “The tyrant of Cratos”.

On the Russian territory, different campaigns for the foreign scientists recruitment and enticement were promoted and applied, during the XVIIIth – XIXth centuries, essential actions in the Russia’s battle for the world supremacy against USA.[5]

The proper brain drain phenomenon appears after 1950, when the emigration of the specialists from all areas : science, art, culture, towards potent countries from an economico – financial point of view, becomes a general tendency (USA, USSR); the stress is laid upon the development of the quaternary sector: the scientific research.

The chart presented below represents the evaluation of the measure in which the specialists from different states are or are not tempted to emigrate towards other areas of the globe. The emigration degree is noted from 1 to 7 (1 meaning emigration and 7 excluded emigration).

Chart no. 1. Level of „brain drain” phenomenon

Source:<http://www.cap-lmu.de/fgz/statistics/brain-drain.php>

Analysing the chart presented above, one can notice how the temptation to emigrate from the state of origin towards another state, is low in the countries powerfully developed (USA, Japan, Switzerland, Netherlands, Sweden, Great Britain) and is progressively growing as the state development degree is decreasing (Mexico, Czech Republic, Vietnam, Hungary, Ukraine, etc .) However, several states that behave differently from the rule presented above can be noticed (as more developed the state of origin is as lower the specialists emigration is, and reciprocally). Thus, countries such as Malaysia or Estonia have a smaller specialists emigration risk than countries such as Italy, New Zealand. Here a series of factors interfere beside the economic one, such as the native attachment of certain people to the country of origin or the political, linguistical, cultural, social, religious barriers, etc.

2. Forms of the human capital migration

In this context of a more increased development of the highly skilled labour force circulation, various forms of this one appeared. The Human Resources Development Ministry together with the Education Department from India elaborated

and developed a study regarding the forms of specialists emigration: [6]

- **Brain overflow:** represents the overproduction of specialists on the territory of a state. Because there are too many specialists in a certain sector, a supersaturation of the job market takes place and the market can no longer absorb the excessive afflux of the highly skilled labour force in a certain domain, leading to a growth of the unemployment rate. This surplus of the labour force emigrates towards other countries where the especially skilled labour force demand is very high and obviously the work conditions are superior to those from the country of origin. Some of the countries in this situation are China, India, Pakistan, South Korea, Iran, Nigeria, Philippines and Columbia. Regarding the exporting country point of view, this emigration is perceived as a positive one, reducing the unemployment rate in the respective country, and in the same time, it's favorable for the importing countries which "buy" a well trained labour force, but whose remuneration is, in general, below the local specialists's remuneration.

- **Brain export:** this phenomenon appears when the exporting country state receives from the importing country state some material benefits concretized in a tax when the specialists leave the country, or a cumulation of taxes echeloned during the specialists stay in the importing country. It is difficult to say if the received sums by the exporting state cover the costs for the tuition and instruction of the specialists as well as the possible incomes brought by these ones, on the country of origin territory, during their professional life. A true "school" to prepare the specialists deliberately for their export is placed in Barbados and Philippines.

- **Brain exchange:** implies the mutually advantageous exchange of specialists between two or more countries. The partner countries are in general developing countries, but there are cases in which one of the partner states is a developed country. This type of exchange is seen in a positive manner by both the participant countries, both benefiting from an advantageous change of experience, professionally and socio – culturally.

- **Brain drain:** the emigration of the superior skilled labour force from a weaker developed country into another state with a

superior development level. For the exporting country this is a negative phenomenon, because the state of the respective country doesn't acquire any benefit from the specialist's leaving, but it actually loses the knowledge and the experience of those who leave. From a statistic out of the context could result that this departure is positive, as concerning the reduction of the unemployment rate, even though this is not the case, especially on a long or medium term. It's a proper loss for the exporting country [7]. From the importing country perspective it is an absolutely benefic phenomenon, this one benefiting of a well trained and educated labour force which, usually, accepts a lower payment comparative to the local specialists from the same domain.

As a general conclusion, one can observe that the winner state is the state importing a superior skilled labour force, this one benefiting of quality and professionalism at low costs comparing to the costs regarding the formation and payment of the indigenous specialists.

3. Causes that determine the „brain drain” phenomenon

Overall, one can observe that the main cause is represented by the natural desire of any man to achieve a better living standard, to adequately and naturally satisfy his own needs. Of course, these thresholds can vary from the desire to assure oneself a minimum subsistence level, in the case of low developed countries, up to the pursue of a more luxurios and complex living, professionally and personally, in the case of the superior skilled labour force migration.

Starting from this premise, one can identify the general causes of the labour force migration as well as the particular causes, specific to a certain geographical area, social class, culture, ethnic origin, etc.

General causes

As the labour force migration phenomenon got more accentuated, small statistics could be made regarding the general causes that stimulate or on the contrary, limit the phenomenon's expansion. For this purpose, one can speak about two types of

factors that "attract" and respectively "reject" the so called 'push-factors' și 'pull-factors'.

Factors that determine the "brain drain" phenomenon:[8]

- Push-factors: lack of jobs, poor economic development, low level of salaries, excess and absorption incapacity on the market of specialists, lack of investments in research and development, discrimination in the case of employments and promotions, insufficient material and technical conditions, lack of a leading scientific research culture, insufficient endowments, migration towards the urban areas, the desire to recognise the superior qualifications, old educational systems, old and rudimentary technology.

- Pull- factors: rich labour force demand, developed economy, attractive salaries, jobs specially created for specialists, favorable conditions for research/development, promotion and employment opportunities, adequate material base, well sedimented development and research culture, top endowments, great urban centers attraction, superior labour force exploitation, foreign educational systems prestige, top technology.

Starting from these considerations, generally in antithesis, one can visualize comparatively the representative images of some labour force exporting countries, generally low developed countries and the developed states that attract superior skilled labour force.

In this context, the natural question regarding the insufficient number of specialists from the developed countries appears, or regarding their preference of these states to choose specialists from the developing countries.

Thus, factors such as the following appear:

- the costs necessary to train the specialists in the country of origin are high reported to the number of those who can afford those costs even in the conditions when the purchasing power is superior to the purchasing power from the exporting countries, and thus it is more profitable for the importing countries to use the labour force from other states, the costs for the basic instruction of the specialists being already realized, these ones needing just some trainings in order to accomodate and eventually to overspecialize.

- the high degree of civilization from the importing countries, which is reflected by a more stable labour force market, capable to absorb better the labour force, thus being no major discrepancies between labour demand and labour offer on the developing countries markets.

Particular causes

Being a complex phenomenon, this must be seen in detail, in order to observe a series of factors that influence the labour force migration. The ethnical factor has a strong influence. For example, going back to Israel for the jews from all over the world especially from the countries of Central and Eastern Europe. But beside all that, there are jews who decide to stay in the host country, due to the better living conditions and to the fact that they integrated and were accepted religiously, culturally, politically, as for example the jews from USA or even from Germany. Other particularities can be found in the fact that the official language of a country is an international language (English, French) and this way the emigrants are more willing to come in the respective countries than to a country more developed economically, but with a more difficult language, such as Germany, Sweden, nordic countries in general. A special characteristic can be found in the Japanese system of the labour force market, where it is mandatory to pass through all the formation stages as specialist to reach a leading position and implicitly to have a certain age, comparatively to the American system where there are young and very young top managers, the access system being much more freely. Of course, the main difference in this case is represented by the society and its culture, the Japanese culture being a more particular one, which couldn't be easily applied to another society.

4. Contemporary tendencies of the „brain drain” phenomenon

Within the current society where the globalisation phenomenon is more and more accentuated as the the borders between the states open for the free circulation of marchandise and human capital, one witnesses a general tendency namely the brain migration, which is no longer one way

as several decades ago, but a real „brain circulation.” The new economies, found in a continuous and rapid development, from India, China, South Korea, Taiwan attract new specialists which return to the country of origin after they had a great success abroad, practicing in top domains such as: IT, medicine, constructions, scientific research. Once returned to the country of origin, these ones bring their contribution to the domain they practiced in externally, through the experience they gained, but also with their own capital. In this context, the state plays an extremely important role. Firstly, it's about the initial role of the exporting country state, which can intentionally and deliberately support the emigration for a certain period of time on the territory of another state with the precise purpose to return to the country of origin and to contribute to the development of the studied domain. The second important role of the exporting state is the one of integrating in the work field those who came back, and to offer them the necessary conditions to practice and develop the knowledge obtained abroad.

Unfortunately, in the states with a lower living standard and especially the states in a transition period as well as the states poorly developed (the African continent), brain emigration isn't made willingly but rather due to the wish of a better life, in a system that appreciates values and offers them the possibility to develop on all levels. In these states, in case the specialists come back, most of the times, they hit a wall of unclarities and indifference from the system they came back into, comparative to the system they worked and developed in. But in the states that are emerging, such as India, for the returned specialists better conditions are created, or at least they are trying to do so, taking for example Bangalore – India, the so called Silicon Valley, where the explosion of the soft industry was made by the specialists returned from USA.

The more pronounced development and the entrance of the multinational companies on new markets also represent a current tendency and in the same time a form of brain circulation. Therefore, one can observe that the accentuation of the globalisation process has many nuances depending on the country in question, in terms of brain circulation globally. Thus, the powerful

states can afford to pay a superior skilled labour force which they can continue to train at the highest level and implicitly to profit from this investment, while the countries of origin, highly skilled labour force exporting states, most of the times, can't afford to offer decent living and working conditions in general, in case the specialists would like to return.

To observe more exactly the highly skilled labour force share reported to the labour force total migration, one can analyze the chart below:

Chart no.2 Expatriation rate according to level of education

(1) OECD, Directorate for Employment, Labour and Social Affairs, 2005
(2) NatWest International Personal Banking (NatWest IPB) Expat Wealth Ranking Survey, Sept 2007

Source:<http://www.justlanded.com/var/storage/images/media/images/expatriates-expat-rate/4941641-1-eng-GB/Expatriates-expat-rate.png>

One can observe that in Great Britain, on average 5.6% from the population lives abroad, and 12.2% represents the proportion of emigrants with a higher education reported to the total population with a higher education on the Britain territory. In other words, more than one British specialist out of ten works outside the borders. Also, the emigrant specialists income average is about 43% above the income average of specialists working in Great Britain. More than 30% from the expatriated specialists have annual salaries above 100.000 euro, to which different benefits are added such as: relocation bonuses, trainings paid by the

company, house, etc. At the other extreme one can observe USA, where only 0.7% from the American citizen live outside the borders and only 0.4% from the total of specialists chose to work in other states. This can be explained by the fact that USA is a world leader regarding top research and technological development, and the American capitalism sustains and promotes the values in all fields, absorbing the specialists from all countries of the world, in order to accentuate the progress. Also, at a short distance from USA the case of Japan can be noticed. Here only 1% from the Japanese population works outside the state and only 0.4% from the total of specialists work in other countries. Of course, here it's all about another perspective, another point of view regarding the culture and civilization of the Land of the Rising Sun based on consistency and loyalty, fundamental characteristics on the job market.

The emigration directions are traced mainly after the level of development of the two countries, the exporting and the importing country. Thus, the main geographical routes globally are: from East to West (Europe to North America; Asia to Europe, North America and even the Middle East and North-East of Africa) and from North to South (Latin America to North America; Africa to Europe and North America).

One can observe that the majority of routes lead to North America, a phenomenon easy to understand due to the work and living conditions offered to the specialists that emigrate in that area. Also, Canada is a magnet with a strong influence on specialists, this one giving in its turn advanced work conditions, and the official languages (English and French), being world languages, represent an advantage. But, the most important advantage for the immigrant specialists, by comparison with North America is the fact that work visas are more easy to obtain for Canada, the main decisive factor for granting the visa being for the emigrant to have previously found a Canadian employer. From these perspectives, not only the specialists from the developing countries are tempted to emigrate in Canada but also those from the developed countries from Central and Western Europe, and even from USA. Australia is also a very searched

host country due to the fact that the visa is obtained more easily than the work visa for the USA. For the destination Australia, for the specialists there is a certain visa dedicated to them, called the "Skilled Migration Visa", which allows the stay and work on the Australian territory indefinitely.

„Brain circulation" takes place in the easiest way on the EU territory, being practically about a liberalization of the labour force on the EU territory. Thus one cannot speak about a proper migration, in the context of borders liberalization, but more about a huge common market of the labour force.

5. Conclusions

The globalisation can be seen as a process that created vital interdependencies between the majority of the world states, but which deepens even more the discrepancies between the living standards among them, as the powerful states can afford to exploit the cheap labour force from the poorly developed countries.

At the first sight, this could seem a totally beneficial phenomenon for all states, but this is far to be true, being more an emerging capitalist market (i.e. the ex socialist states), where the strong become stronger, and the lower class deepens even more.

On the overall, in the actual context of a more emphasized globalisation, soon, it won't be about an emigration/immigration, but about the free circulation of the labour force, on a free market. Concretely, in the case of multinational companies activity expansion and implicitly the superior skilled labour force migration (top management), from the mother company country of origin to the host country, the migration of the labour force is not in question, but the free circulation of the labour force.

Abstract

Normally, the main causes of cyclical fluctuations in economic activity are related to changing levels of investment and government spending. This is because a large proportion of consumer expenditure is financed from loans more than current income. As a result, consumption begins to be increasingly influenced by interest rate. Also size reduction policy interventionist government spending led to different effects on the overall level of economic development. Cyclical changes may thus alter the macroeconomic conditions and regional supply, with direct influence on the level of potential output in two ways:

- by increasing or reducing prices of primary goods;
- the impact of technological innovations on the level of economic activity.

In terms of historical changes in the level and quality of energy sources or means of transport are significant examples in this regard.

Key words: regional disparities, GDP per inhabitant, recession

J.E.L. classification: R 11

With the start of a particular stage of economic cycle, economic impacts are cumulative, as a result of acceleration and multiplication mechanisms.

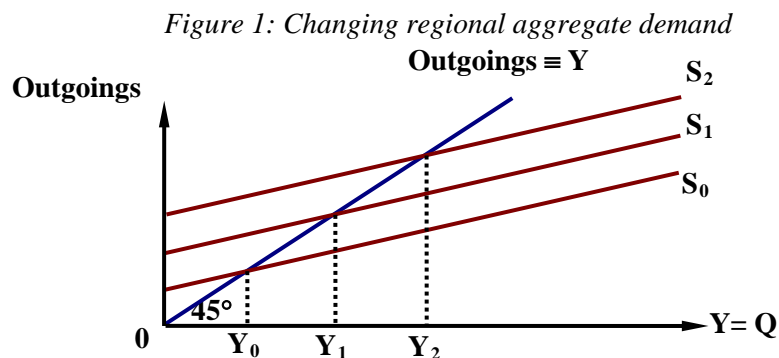

Multiplier concept is introduced taking into account that the revenue can be used for: Current consumption of goods and services produced within the regional or national economy (C), savings (S), consumption of imported goods (M) and pay taxes (T)

Accordingly, the multiplier can be highlighted:

$$Y = C + S + M + T$$

$$k = \frac{1}{1 - c'} \quad \text{sau} \quad k = \frac{1}{s' + z' + t'}$$

At regional and national level, the multiplier is determined by the value of marginal propensity to consume. The higher the multiplier value, the greater will be its effect on production levels, according to a modification of the aggregate expenditure data (see Figure 1).

Multiplier effect is that any change in the level of expenditure will have an effect greater than the regional's output will help to increase or decrease the level of cyclical economic activity.

Accelerator concept shows that an accelerated growth of production is required when the investment increases. On the other hand, investment must cover the need for goods and services and depreciation of assets.

During the recession, investment is so low that the stock of capital at the regional and national decreases. This is because the replacement rate of physical capital is lower than the rate of depreciation of such capital.

Formally, the effect is evidenced by an accelerator investment equation of the form:

$$I_t = v \cdot VN_t + d \cdot K_{t-1}$$

where :

I - investment;

K - capital stock;

VN - national income;

v - capital consumption per unit of product;

d - replacement investment;

t - current time;

t - 1 - previous period.

Since capital consumption per unit product varies greatly among different industries and economic activities, a region whose economy is dominated by industries with a high rate of capital per unit of product (steel, chemicals, high volume), will need by as much capital.

Conversely, regions that have economic activity rates of capital consumption reduced product (textile industry) will be able to develop a much smaller investment.

When the regional economy through the recession phase of the economic cycle, some workers become unemployed and will not pay, inter alia, income tax. Others will voluntarily reduce costs, due to lower their income, which attracts a decrease in income taxes that they pay. As a result, the flow of revenues derived from tax revenues at the regional level will be reduced.

On the other hand, the recession the unemployment rate increases and the government will be forced to pay larger sums into the account of unemployment. So the financial flow, coming from central government and headed to the region affected by the recession, will increase.

Combined with the reduction in income from fees, the government cash flow - the region will increase the volume of public expenditure at regional and national levels.

If, however, the economy is in the phase of recovery, unemployment will be reduced while reducing government spending related to the payment of unemployment benefits. In addition, more economic activity will require additional work factor, which will result in an increase in workers' incomes, and hence an increase in taxes on their income. In this phase of economic cycle, net government spending will decrease.

If a zero growth may be seen an increase in regional unemployment. This could mean that: income of a region should be increased by an annual rate of more than 3% to maintain the constant use of factors of production. To ensure that the utilization rate to increase by 1% per year will be the level's output to increase by at least 5%.

Largest European Commission document on regional development in 2010 as an essential element of the analysis considers intra and inter-regional disparities in GDP development community, whose average value was calculated to be 24,900 PPS. Community Areas with the highest GDP per capita are in the southern United Kingdom and Germany, northern Italy, Belgium, Luxembourg, Netherlands, Austria, Ireland and Scandinavia. The regions capital Madrid, Paris and Prague also fall into this category. Regions with the lowest GDP per capita is concentrated in the south, west and south-eastern periphery of the European Union, Eastern Germany, the new Member States and Candidate Countries for membership (Croatia, Former Yugoslav Republic of Macedonia and Turkey). Within the EU27, GDP per capita varies from 6400 PPS (EU average 26%) in the region Severozapaden (Bulgaria) to 83 200 PPS (334% of EU average) in the region of Inner London (United Kingdom). The ratio between these two extremes is 13,1:1 development.

Other highly developed regions are: Luxembourg with 68 500 PPS (275% of EU average), with 55 000 PPS Bruxeles (221%), Hamburg with 47 800 PPS (192%), Prague 42 800 PPS (172%) and Ile de France (169%).

125% of the 41 regions exceeding the growth rate of the Community. Of these, nine are in Germany, five each from the Netherlands and the United Kingdom, four from Austria, three from Spain and Italy, 2 each from Belgium and one from Finland and Czech Republic, Denmark, Ireland, Greece, France, Slovakia and Sweden and Luxembourg.

Prague is actually the region with the highest GDP per capita in the new Member States. Bratislava (Slovakia) with 39 900 PPS (160%) holds the 12th position among the most developed regions.

Prague and Bratislava regions are exceptions to the new Member States as the next best-placed regions of these countries occupy 94 seats (Zahodna Slovenija - Slovenia with 26 600 PPS - 107%), 111 (Közép-Magyarország - Hungary 25 600 PPS - 103%) and 146 (23 300 PPS Cyprus - 94%) With the exception of four regions

(Bucharest-Ilfov Romania, Mazowieckie Poland, Malta and the Czech Republic Střední Čechy), all other regions of the 12 new EU Member States have a GDP per capita less than 75% of EU average. The less developed economic regions are located in Bulgaria and Romania. It has a negative record Severozapaden in Bulgaria (26% of the EU27 average), followed by North-East of Romania, and Yuzhen tsentralen Severen tsentralen in Bulgaria (all 27% of the EU27 average).

Of the 66 regions with a lower growth rate of 75% of the EU27 average, 15 are from Poland, Greece and Romania by 7, 6 each from Bulgaria, the Czech Republic and Hungary, four each from Italy and Portugal, three in Slovakia , 2 from France, 1 from Spain, Slovenia and the United Kingdom and throughout Estonia, Latvia and Lithuania (see Table 1).

Table 1: Regional GDP per inhabitant in the EU27

Regions with the highest rates of growth (in PPS, EU27 = 100)			Regions with the highest rates of growth (in PPS, EU27 = 100)

Source: Eurostat, Newsrelease, Regional GDP per inhabited in 2007, no.25, 18/2/2010.

As a result, in 67 EU regions, GDP per capita is less than 75% of the EU average, three quarters of their number being in the new Member States. On the other hand, regions with a GDP per capita less than 125% of the EU27 average covering 20.6% of Community population.

Most EU population (55%) live in regions with a GDP per capita of between 75% and 125% of the EU27 average. In 28 regions, with a population representing 9.9% of total EU GDP per capita is less than 50% of the EU27 average. With the exception of French Guiana, all other regions are in the new EU member states.

Of the 30 NUTS2 regions of the candidate states, only two (Sjeverozapadna Hrvatska Croatia and Istanbul) have a GDP per capita close to 75% of the EU27 average. Nine regions in candidate countries for accession to the EU 27 have a GDP per capita less than 50% of EU average.

The lowest levels of GDP per capita in the 27 Member States and three candidate states you have regions Van (15% of average EU-27) and Agriculture (18.2%) located in eastern Turkey. There are significant regional differences even between EU27 Member States and between the candidate. The largest such differences are manifested in Turkey, where the ratio between the developed and least developed region is 4,9:1 in the United Kingdom (4,6:1) and Slovakia (3,5:1).

The smallest regional disparities are found in Slovenia and Sweden (1,5:1) and the Netherlands (1,6:1). Moderate regional differences related to GDP per capita (less than 2:1) shall meet, except Slovenia and Croatia, only in the EU15.

In all EU 12 Member States, Croatia and some 15 member states, an important part of economic activity is concentrated in the capital. Often, these capitals have the highest GDP per capita. As is the case of capital: Bruxelles, Sofia, Prague, Athens, Madrid, Paris, Lisbon, Budapest, Bratislava, London, Warsaw and Bucharest. If it makes a comparative analysis between the extreme values of 2000 and 2010 reveals that the evolution of the EU15 states was very different from that of the EU 12 states. While this gap has decreased in all EU15 Member States, in several EU 12 Member States and Croatia, has widened.

An interesting aspect is related to the mitigation of regional disparities in the EU27. This situation has advantages those regions that have managed to obtain an average annual growth rate of 3% higher than average. These regions are considered dynamic.

In contrast, some regions in the EU15 undergoes characterized by loss of growth rate. Developments in both directions, this process leads to extreme differences whose values range from 52% for the region Bratislavsky kraj (Slovakia) and 35% for Bruxelles.

Following the most dynamic community are those in peripheral regions west and north east. Economically dynamic regions are also found in Croatia and Turkey. For the EU15 recorded strong economic growth, Spain, Ireland, Greece, United Kingdom, Finland and Sweden. On the other hand, the growth trend has flattened in most EU15 Member States.

Some regions of Italy, Belgium and Austria could not reach EU average growth during 2000-2010. In France, however, the period, all regions except Guadeloupe and Martinique, have recorded a higher growth EU27 average. The same positive trend they had two thirds of the regions of Portugal.

In the EU 12, EU economic growth above the average were recorded in the Baltics, Romania, Czech Republic, Slovakia and in most regions of Poland. Croatia, Former Yugoslav Republic of Macedonia and Turkey have achieved many of the region's economic growth above EU average for the period 2000-2010.

36 EU regions have exceeded the EU average by more than 10%. Of these, 20 are in the EU 12. Top 10 regions with the fastest growth coming from nine Member States. Capital regions continue to have high growth rates in all EU states. EU 12 region which had the greater economic growth in 2000-2010 is the Western Region (Romania), an increase of 21.4%.

At the same time, of the 31 regions had lower growth than the EU27 average of 10%, 15 are from Italy, 4 in Belgium and three in France, which shows a certain concentration of this phenomenon.

In the EU 12, the period examined, only three regions have experienced an economic decline from the Community average: Malta (-7.2%), Nyugat-Dunantul Hungary (-1.3%) and Zachodniopomorskie Poland (-0.2%).

Trend growth in Turkey during 2000-2010 was heterogeneity. The process of economic approximation (catching up) ran well in the western regions of the country, particularly in Istanbul and Bursa.

Eastern regions and islands, especially Kayseri and Agriculture, received an above average growth.

In contrast, other regions of the eastern Mediterranean coast, particularly Adana, have substantial economic contraction.

Catch-up process in the EU 12 reached 1.5% annually during 2000-2007, compared with the EU27 average. This process was much faster than developed in the 90s. GDP per capita in the EU 12 states increased from 45% of the EU27 average in 2000 to 56% in 2007. The economic crisis has caused a gradual decrease in growth rate of EU 12, but to a lesser extent than in the EU15 Member States. In fact, EU regions hardest-hit have been those with a GDP per capita and very dependent on exports.

According to this conclusion, the regions should participate actively in inter-regional trade if they want to become prosperous in economic terms - social. More prosperous regions tend to achieve balance of payments surplus, while the less competitive regions have a long-term deficit. At regional level, analysis of international trade is extremely difficult, simply because a region achieved commercial operations to other regions in the same state as operations such as foreign trade. It is nevertheless undeniable that a combination of global trade freer and more developed regions can help to open for import and export. To understand why some regions were more successful than others from their exports and specializing in manufacture and export of certain goods, we use the theories of international trade.

As long as the regions trade done directly with the world, items that affect international trade can easily be revealed at the regional level. This is particularly so since the traditional trade theory was initially developed based on inter-regional and then international.

Ricardian theory and, later, Heckscher - Ohlin tried, in turn, explain the importance of regional trade has on economic growth. The current economic research, however, exceeded the limits imposed by the classical theories, now there are at least five performance models.

The first two relate to the technological gap theory and the theory of the production cycle. Both models highlight the role of innovation and technical progress. Other models are those relating to industrial location theory (Hay and Harrigan), Inter-sectorial trade and trade within firms.

Technological gap theory argues that a region that may generate an increased flow of innovations and new products will gain an advantage from this production. This advantage will not be permanent, but will create a gap of imitation and other regions until they can accomplish the same products. This gap covers two aspects of imitation: original, innovative region will make the new product but it will not export, because there still exists demand for it, consumers in other regions, not knowing it yet;

Then, the region will start exporting a new product in other regions. This stage is the goal of creation. With time, taking over the production and to other parts of the good, innovative region will gradually lose the export advantage and domination. Because regions are open in terms of commercial time that widespread production of a new good will be quite short. The only viable obstacle to the movement of information between regions is the law on copyright, patents and innovations from each country.

Production cycle theory shows that some regions may be the most favourable place for the location (location) to the production of an asset at a certain stage of his life, while other regions may benefit in other stages of the life cycle of the good. Several stages have been identified:

- early stage: early stage is that region that is most capable of providing scientific research and development inputs, and a special skill labour, to ensure a monopoly of production.

- the high level of wages and demand at regional level will also promote, develop new products. At this stage, the high cost of production is a particular problem, as long as other regions cannot yet produce the good;

- second stage: second stage, the production becomes more standardized and production technology is becoming more common. These processes allow other regions to compete for export with the initial region. Over time, new producers, having the advantages of lower wages and fewer workers will make it hard for innovative region;

- the final phase: the final stage, the regions receiving the lowest salary levels and semi-qualified labour abundant factor will be favoured in the standardization process of production. Initial innovative region can become progressively unable to compete in the local market.

A third model, which explains the regional trade specialization is based on the analysis of industrial location. Classical location theory argues that the branches are placed in office by minimizing costs. Most important categories of costs are related to transport and work factor. In addition, economic agglomerations and economies of scale are particularly important location costs.

Inter-sectorial trade known phenomenon of attention lately. In the theory of corresponding regions are considered distinct focus their products on which export them in exchange for other products. It appears, therefore, a substantial quantity of goods Inter-sectorial, which is the subject of trade between regions.

Grid Concept in Business Application

Timofte Carmen

Academy of Economic Studies, Bucharest

carmen@ase.ro

Abstract

Grid is a centerpiece of the "utility computing" marketing drive taken up by nearly every vendor. Load balancers, clustering solutions, blade servers—just about any product can come to market with a grid label. The grid technologies, like smart grid, and services will help companies to be winners in the acerb competition. This paper presents an overview of grid's technologies, services and application and try to preview the direction's trend.

Key words: grid computing, OGSA, OGSI, services.

J.E.L. classification: L86

1. Introduction

The technology behind grid isn't new. Its roots lie in early distributed computing projects that date back to the 1980s, where scientists would connect multiple workstations to let complex math problems or software compilations take advantage of idle CPUs, dramatically shortening processing times. For years, vendors and IT departments eyed this opportunity to dramatically increase processing power by employing existing resources. But only recently have the tools arrived to put general business applications to work on a grid.

By many accounts, average system utilization across organizations is 15% to 20% today, while obviously the ideal would be around 80%. What's more, some 20% of IS budgets go to operations, marginally less than the 25% earmarked for capital investments. We've created large, underutilized, complex environments that are costly to maintain. So there is a huge need to do this better, and the prevailing thinking at this point seems to be that grid is the answer.

The smart grid cleantech industry is estimated to hit \$11.8 billion by the end of 2015 and the companies must to find out how to be at the forefront of this rapidly growing market.

Grid computing joins together many individual computers, creating a large system with massive computational power that far surpasses the power of a handful of supercomputers. Because the work is split into small pieces that can be processed simultaneously, research time is reduced from years to months. The technology is also more cost-effective, enabling better use of critical funds.

The best candidates for grid are applications that run the same or similar computations on thousands or millions of pieces of data, with no single calculation dependent on those that came before. These so-called embarrassingly parallel applications—which include numerous scientific tools, cryptography, and the actuarial and derivative examples mentioned earlier—are ideal for grid, as they scale almost perfectly with the applications able to take advantage of every new processor you throw at them.

2. Grid applications and type

A Grid platform could be used for many different types of applications, like:

- distributed supercomputing (exp. stellar dynamics);
- high-throughput (exp. parametric studies);
- on-demand (exp. smart instruments);
- data intensive (exp. data mining);
- collaborative (exp. collaborative design).
- service-oriented computing (exp. application service provides and the users' QoS requirements driven access to remote software and hardware resources).

Grid computing continues to evolve. Analysts and vendors now identify at least three types of grids: computational grids, data grids and collaborative grids.

While most people think of computational grids, enterprises are looking into data grids that don't share computing power but instead provide a standardized way to swap data internally and externally for data mining and decision support (music sharing systems like LimeWire and Kazaa are examples).

Collaborative grids, meanwhile, let dispersed users share and work together on extremely large data sets. (The NEESgrid, for example, allows earthquake researchers to share data and even research equipment as virtual teams over the Internet.) Clabby of Clabby Analytics also notes that subgenres such as utility grids, enterprise optimization grids and others continue to develop. In short, grid isn't going away.

Grid projects, such as NASA's Information Power Grid, The GriPhyn, and NeesGrid, are mostly created and operated by universities and government research institutions. One of the earliest and most popular public examples of grid computing is SETI@home. This project uses the processing power of more than 500,000 personal computers from around the world in its quest to search for life in the galaxy.

The most important grid players and their application, are:

- Ascential (*ascential.com*): Enterprise Integration Platform that supports data integration grids.
- Avaki (*avaki.com*): Avaki Data Grid creates a unified catalog of data across a network.
- DataSynapse (*datasynapse.com*): GridServer lets customers move existing applications to grid environment.
- Dell (*dell.com*): Partnered with Platform Computing (see below) to provide grid-enabled systems for CPU-intensive computing purposes.
- Enterprise Grid Alliance (*gridalliance.org*): Group formed by Oracle, HP and others to create enterprise-oriented grid standards.
- Global Grid Forum (*ggf.org*): Standards body that creates and publishes grid computing standards.

- The Globus Alliance (*globus.org*): Group offers open-source development kits based on Global Grid Forum and Oasis. Will likely include other standards.
- Hewlett-Packard (*hp.com*): Utility Data Center provides rapid reallocation of computing resources. Works on a variety of corporate grid products and services.
- IBM (*ibm.com/grid*): Grid is a central part of IBM's autonomic computing model. Numerous products and partnerships in place.
- Oracle (*oracle.com/grid*): Released Oracle 10g database early this year. Built-in support for grid computing resources.
- Platform Computing (*platform.com*): Software that consolidates computing resources and provides an architecture for grid-enabled applications.
- SAP (*sap.com*): Currently piloting a project to grid-enable SAP applications.
- Sun Microsystems (*sun.com*): N1 Grid engine combines grid and clustering.
- United Devices (*ud.com*): Offers enterprise grid software and hosting service for grid-on-demand.

3. Standards and forums

Creating tools that work in distributed, heterogeneous environments is a field ripe for standards, something both grid vendors and customers realize. Understanding that concern, vendors and researchers are involved in several standards bodies, like: the Global Grid Forum (GGF), the Enterprise Grid Alliance (EGA) and the Globus Alliance.

- The GGF—whose members include Ascential, DataSynapse, Hewlett-Packard, IBM, Microsoft, Oracle, Platform Computing and Sun—works to develop standards intended to create a wide range of interoperable grid-computing environments and applications.
- The EGA— whose members include Oracle, HP, Sun and others (though notably not Microsoft, IBM or Platform Computing)—has set goals of providing standards aimed at grid-enabled

enterprise applications—what it claims will be a subset of the GGF's work.

- Globus was formed by a group of research organizations, including Argonne National Laboratory and the University of Chicago and sponsored by the Defense Advanced Research Projects Agency and the National Science Foundation. The group implements standards through its Globus Toolkit, an open-source development suite that lets software makers jump-start their grid development. Current standards include the Open Grid Services Architecture (OGSA), the Open Grid Services Infrastructure (OGSI) and—most recently—the Web Services Resource Framework, which will supplant OGSI later this year, according to GGF, and allow grid software makers to use common Web services standards to identify and utilize grid-computing resources.

4. Designing a Grid

An ideal Grid environment will therefore provide access to the available resources in a seamless manner such that physical discontinuities, such as the differences between platforms, network protocols, and administrative boundaries become completely transparent. In essence, the Grid middleware turns a radically heterogeneous environment into a virtual homogeneous one.

The following are the main design features required by a Grid environment.

- *Administrative hierarchy* - is the way that each Grid environment divides itself up to cope with a potentially global extent; determines how administrative information flows through the Grid.
- *Communication services*- are diverse, ranging from reliable point-to-point to unreliable multicast communications. The communications infrastructure needs to support protocols that are used for bulk-data transport, streaming data, group communications, and those used by distributed objects. The network services used also provide the Grid with important QoS parameters such as

latency, bandwidth, reliability, fault-tolerance, and jitter control.

- *Information services*. A Grid is a dynamic environment where the location and types of services available are constantly changing. A major goal is to make all resources accessible to any process in the system, without regard to the relative location of the resource user. It is necessary to provide mechanisms to enable a rich environment in which information is readily obtained by requesting services. The Grid information (registration and directory) services components provide the mechanisms for registering and obtaining information about the Grid structure, resources, services, and status.
- *Naming services* - are used to refer to a wide variety of objects such as computers, services, or data objects; provides a uniform name space across the complete Grid environment. Typical naming services are provided by the international X.500 naming scheme or DNS, the Internet's scheme.
- *Distributed file systems and caching*. Distributed applications, more often than not, require access to files distributed among many servers. A distributed file system is therefore a key component in a distributed system. From an applications point of view it is important that a distributed file system can provide a uniform global namespace, support a range of file I/O protocols, require little or no program modification, and provide means that enable performance optimizations to be implemented, such as the usage of caches.
- *Security and authorization*. Any distributed system involves all four aspects of security: confidentiality, integrity, authentication and accountability. Security within a Grid environment is a complex issue requiring diverse resources autonomously administered to interact in a manner that does not impact the usability of the resources or introduces security holes/lapses in individual systems or the environments as a whole. A security infrastructure is the key to

the success or failure of a Grid environment.

- *System status and fault tolerance.* To provide a reliable and robust environment it is important that a means of monitoring resources and applications is provided. To accomplish this task, tools that monitor resources and application need to be deployed.
- *Resource management and scheduling.* The management of processor time, memory, network, storage, and other components in a Grid is clearly very important. The overall aim is to efficiently and effectively schedule the applications that need to utilize the available resources in the Grid computing environment. From a user's point of view, resource management and scheduling should be transparent; their interaction with it being confined to a manipulating mechanism for submitting their application. It is important in a Grid that a resource management and scheduling service can interact with those that may be installed locally.
- *Computational economy and resource trading.* As a Grid is constructed by coupling resources distributed across various organizations and administrative domains that may be owned by different organizations, it is essential to support mechanisms and policies that help in regulate resource supply and demand. An economic approach is one means of managing resources in a complex and decentralized manner. This approach provides incentives for resource owners, and users to be part of the Grid and develop and using strategies that help maximize their objectives.
- *Programming tools and paradigms.* Grid applications (multi-disciplinary applications) couple resources that cannot be replicated at a single site even or may be globally located for other practical reasons. A Grid should include interfaces, APIs, utilities, and tools to provide a rich development environment. Common scientific languages such as C, C++, and Fortran should be available, as should application-level interfaces such as MPI and PVM. A variety of programming paradigms should be supported, such as

message passing or distributed shared memory. In addition, a suite of numerical and other commonly used libraries should be available.

- *User and administrative GUI.* The interfaces to the services and resources available should be intuitive and easy to use. In addition, they should work on a range of different platforms and operating systems. They also need to take advantage of Web technologies to offer a view of portal supercomputing. The Web-centric approach to access supercomputing resources should enable users to access any resource from anywhere over any platform at any time. That means, the users should be allowed to submit their jobs to computational resources through a Web interface from any of the accessible platforms such as PCs, laptops, or Personal Digital Assistant, thus supporting the ubiquitous access to the Grid. The provision of access to scientific applications through the Web (e.g. RWCPs parallel protein information analysis system) leads to the creation of science portals.

5. Services

From the end-user point of view, Grids can be used to provide the following types of services.

- *Application services* – offers application management and provides access to remote software and libraries transparently; there are implementing with Web services technologies; they build on computational and data services provided by the Grid. (exp.: NetSolve).

- *Computational services* - provides secure services for executing application jobs on distributed computational resources individually or collectively. Resources brokers provide the services for collective use of distributed resources. They formed a computational Grid, like: NASA IPG, the World Wide Grid, the NSF TeraGrid.

- *Data services* – provides secure access to distributed datasets and their management. To provide a scalable storage and access to the data sets, they may be replicated, catalogued, and even different datasets stored in different locations to create an illusion of

mass storage. The processing of datasets is carried out using computational Grid services and such a combination is commonly called data Grids. Sample applications that need such services for management, sharing, and processing of large datasets are high-energy physics and accessing distributed chemical databases for drug design.

- *Information services* - provides extraction and presentation of data with meaning by using the services of computational, data, and/or application services. The low-level details handled by this are the way that information is represented, stored, accessed, shared, and maintained. Given its key role in many scientific endeavors, the Web is the obvious point of departure for this level.

- *Knowledge services*. These are concerned with the way that knowledge is acquired, used, retrieved, published, and maintained to assist users in achieving their particular goals and objectives. Knowledge is understood as information applied to achieve a goal, solve a problem, or execute a decision. An example of this is data mining for automatically building a new knowledge.

6. Web Services

Grid computing makes it possible to dynamically share and coordinate dispersed, heterogeneous computing resources. Flexibility and ubiquity are essential characteristics of Web services technologies such as WSDL (Web Services Description Language), SOAP (Simple Object Access Protocol), and UDDI (Universal Description, Discovery, and Integration).

The Open Grid Services Architecture (OGSA) combines technologies to unlock and exploit grid-attached resources. OGSA defines mechanisms to create, manage, and exchange information between Grid Services, a special type of Web service. The architecture uses WSDL extensively to describe the structure and behavior of a service. Service descriptions are located and discovered using Web Services Inspection Language (WSIL). By combining elements from grid computing and Web services technologies, OGSA establishes an extensible and interoperable design and development framework for Grid Services

that includes details for service definition, discovery, and life-cycle management.

7. OGSA

The Open Grid Services Architecture (OGSA) combines technologies to unlock and exploit grid-attached resources. OGSA defines mechanisms to create, manage, and exchange information between Grid Services, a special type of Web service. The architecture uses WSDL extensively to describe the structure and behavior of a service. Service descriptions are located and discovered using Web Services Inspection Language (WSIL). By combining elements from grid computing and Web services technologies, OGSA establishes an extensible and interoperable design and development framework for Grid Services that includes details for service definition, discovery, and life-cycle management.

OGSA defines and standardizes a set of (mostly) orthogonal multipurpose communication primitives that can be combined and customized by specific clients and services to yield powerful behavior. OGSA defines standard interfaces (portTypes in WSDL terminology) for basic Grid services.

Grid applications use grid tools and middleware components to interact with the fabric.

OGSA introduces several service concepts that need to be adopted in order to qualify as Grid services. Necessary components are *factories, registries, and handle maps*. Additional mechanisms that can be used to build our data grid are *notification* and *lifetime management*.

From a software-design perspective, a grid can be viewed as a collection of self-contained computing services that can be described, published, located, and invoked over any type of network. Services are location-independent and dynamic, span multiple computing architectures, and reach across administrative domains. The design principles of OGSA reflect a combination of elements from Web services and grid computing:

- *Resource virtualization*: each grid component is considered a service.
- *Standard interface definition mechanisms*: enabling multiple protocol bindings and transparency between local or remote services.
- *Standard foundation services*: defining service semantics, reliability and security models, and core functions such as life-cycle management, or discovery.
- *Implementation independence*: support for multiple development languages and hosting environments including Java, COBOL, C, J2EE, CICS, and .NET.

Since a grid consists of both existing and new hardware and software, multiple variations of communication protocols, security schemes, and transaction management systems exist and cooperate at the same time. Today's grids tend to be a patchwork of protocols and noninteroperable "standards" and difficult-to-reuse "implementations." The OGSA uses Web services technologies like WSDL, SOAP, and WSIL to abstract platform and implementation differences, giving transparent access to grid services.

Fundamental to OGSA are WSDL and interfaces for dynamic discovery and life-cycle management for a specific type of Web service - a Grid Service. WSDL conventions and extensions are used to describe and structure services, while core service activities are expressed using WSDL interfaces and behaviors. Every Grid Service instance has a unique and immutable name called the Grid Service Handle. Lifetime management is provided by mandatory support for the operations Destroy and SetTerminationTime.

8. Conclusion

Grid technologies represent a significant step forward in the effective use of network-connected resources, providing a framework for sharing distributed resources while respecting the distinct administrative priorities and autonomy of the resource owners. A grid can also help people discover and enable new ways of working together — providing a means for resource owners to trade unused cycles for access to significantly

more compute power when needed for short periods, for example, or establishing a new organizational or cultural paradigm of focused investments in common infrastructure that is made available for broad benefit and impact.

The combination of the confluence of developments:

- the maturation of grid technology
- general consensus that the future of computing is about networked, low-cost components
- the emergence of service oriented architectures, or Web services seems to add up to a potent force, a sensible image of the future.

We have new applications on the horizon that will give us further impetus, one being efforts to instrument anything and everything of value - sensors in/on everything in every field, from medicine to military and manufacturing. This will create a flood of raw, real-time streaming data.

E-Commerce Protocols: Overview, Trend and Verification

Timofte Carmen

Academy of Economic Studies, Bucharest

carmen@ase.ro

Abstract

Many researchers have looked at the problem of verifying e-commerce protocols, but much work remains to be done. On the final, I present the trends for the utilization of formal methods for the verification of modern complicated protocols and protocol suites for the real commercial world.

Key words: E-commerce, protocols, SET, AADS, 3D Secure, SSL.

J.E.L. classification: L86

1. Introduction

Electronic commerce requires protocols of great complexity. To make a purchase over the Internet, the customer typically submits his credit card number to the merchant, protected by a protocol such as SSL. However, many potential customers are uneasy about revealing their credit card number over the Internet. The SET protocol has been proposed by a consortium of credit card and software companies.

SET aims to protect sensitive card-holder information, to ensure payment integrity and to authenticate merchants and card-holders.

The paper provides a review of the existing e-commerce protocols, making an analysis of their most important characteristics. The purpose is to determine the trends and to present a formal method for verification of these protocols.

2. Overview of existing protocols

All existing protocols use *cryptographic functions* like: message digest (integrity), secret key encryption (privacy), public key, encryption (privacy and authentication), digital envelopes (integrity and privacy),

digital signatures (authentication), digital certificates (authentication).

E-commerce protocols that were developed and some of them, used, more often or less often, are:

- **SET** (Secure Electronic Transaction)- in 1996 it was developed by Visa și Mastercard, with the assistance of IBM, Microsoft, Netscape, GTE, SAIC, Terisa and Verisign;
- **iKP** (Internet Keyed Payments Protocol) – it was developed by IBM, the Research Center T.J.Watson in collaboration with Zurich Research Laboratory; is a protocol based on public key to making payments on the Internet, involving at least three parties.
- **Secure Courier** – it was proposed by Netscape, to create a secure electronic commerce on the Internet. It wants to be a protocol for the next level of SSL.
- **OPT** (Open Trading Protocol)- it was created in 1997 by the consortium of 28 companies (IBM, Oracle, Sun Microsystems, Netscape, Nokia, HP, AT & T, Fujitsu, etc..) to create a trade on network completely unprotected;
- **SNPP** (Simple Network Payment Protocol)- it was proposed by M.I.T., Laboratory of Computer Science, in 1992;
- **IBS** (Internet Billing Protocol)- it was developed by Carnegie Mellon University in 1994; is inserted into SET; first variant of this protocol is based on Kerberos, using a private key and batch invoices to ensure services both traders and buyers.
- **JEPI** (Joint Electronic Payment Initiative) – it was developed by W3C and CommerceNet
- **EMV** – it was developed by EuroPay and use the chips technology on credit / debit cards;

- **E-Check** (Electronic Checkbook)-working on a SmartCard of FSTC – USA (Financial Services and Technology Consortium);
- **SEPP** (Secure Electronic Payment Protocol) – accepted by MasterCard, IBM and Netscape;
- **STT** (Secure Transaction Technology) – developed by Visa and Microsoft;
- **TLS** (Transport Layer Security) – it's a secure protocol for simple task, who's coding information on credit cards, sent to the Web and ensure that transactions are not intercepted by a third party. It is developed by IETF (Internet Engineering Task Force) and is similar to SSL (Secure Socket Layer of Netscape). It is an open protocol, high level, which allows the addition of new technologies for authentication and encoding / decoding;
- **P3P** (Platform for Privacy Preferences) – developed by W3C and provide a platform for online transaction, allowing different preferences, the cultural norms and environments to various legislative;
- **OPS** (Open Profile Standard) – it's a complement of P3P and provides a secure storage of user profile information. Ensure the protection of individual data and the exchange of data on-line and may establish specific consumer marketing environment.

3. The most important e-commerce protocols

The e-commerce community can choose from a wide range of protocols when designing new applications, but SET distinguishes as the most popular. Companies such as Hitachi, IBM and VeriSign are currently testing SET-based products (for example, Microsoft *Wallet*). Some security experts feel that, for various reasons, SET will never gain widespread acceptance. Whether it does or not, we can be certain that new e-commerce protocols will be developed. Unlike SSL, they will not require the customer to trust the merchant. These new protocols will probably share much of SET's architecture.

SSL (Secure Socket Layer)

SSL protects the communication between a client and a server and provides authentication to both parties. SSL (TLS) resides below application protocols and above transport protocols. Most common use of SSL is to secure web protocol HTTP, TCP/IP and others Internet applications, like e-commerce.

Most Internet merchants use the SSL protocol to prevent eaves droppers from learning customers' account details, adopting the classical idea that bad persons are always outsiders. This arrangement has two major limitations:

- customers must trust merchants to keep these details secure, and merchants may be dishonest or, more often, incompetent.
- merchants must trust customers, who do not sign anything, and have little protection from stolen cards or from customers who repudiate their purchases.

Visa and MasterCard designed the SET protocol to solve these problems by keeping sensitive information confidential and by authenticating Cardholders and Merchants.

The SET Protocol

The overall architecture of SET is based on a rooted hierarchy of *Certification Authorities* (CAs), whose task is to provide customers with digital certificates for signature and encryption. Customers must generate and safeguard their private keys.

A normal run of the SET protocol consists of *five phases*. The first two phases — *Cardholder Registration* and *Merchant Registration* — are used by the protocol participants to register their keys and to get the appropriate certificates. The remaining three phases — *Purchase Request*, *Payment Authorization* and *Payment Capture* — constitute the electronic transaction itself. To accomplish these tasks SET uses numerous combinations of hashing, public key and symmetric key cryptography based on the PKCS#7 standards from RSA Laboratories.

Problems with SET

- significant changes in the existing payment infrastructure
- changes in the business model

- it is slow: banks need 750 transactions per second, and SET offers 1 transaction per second
- the sheer size of the documentation which takes over 1000 pages.
- more substantial obstacle is the protocol's complexity. Academic protocols are typically short, straight-line programs; they seldom go beyond two levels of encryption and generate few secrets.

SET has many features that make its verification hard:

- Multiple nested encryptions and duplicate message fields require abbreviations.
- Ubiquitous generation of random numbers and keys cause a state-space explosion in model checking.
- Many alternative protocol paths make it hard to single out the few key roles used either by manual analysis or by model-checkers to restrict the search space.

SET was based on X.509 certificates with several extensions and was intended to become the *de facto standard* of payment method on the Internet. Despite heavy publicity, it failed to win market share. Reasons for this include: network effect - need to install client software (an e-wallet); cost and complexity for merchants to offer support and comparatively low cost and simplicity of the existing SSL based alternative; client-side certificate distribution logistics. SET needs to be revived by introducing an emerging, alternative technology: AADS - Account Authority Digital Signatures.

AADS (Account Authority Digital Signature)

The most important objective of AADS is to incorporate strong authentication into existing business infrastructures, with public key digital signature. Neither a PIN nor a password is required to be transmitted to the receiver for validating the identity of the sender.

An AADS transaction eliminates the need to append a certificate to a digitally signed transaction. The transaction/document with appended digital signature is all that is necessary for an AADS transaction (with no appended certificate). At the receiving party, the appended digital signature is

authenticated by retrieving the public key from the associated account record (not from an appended certificate).

There have been some early electronic commerce pilots that have relied on certificate-based bindings which minimize the software changes to existing business implementations. Benefits from small pilots would typically be less than expense of modifying existing business process implementations (especially if it hasn't yet been determined exactly what the changes should be long term).

3D Secure

The basic concept of the protocol is to tie the financial authorization process with an online authentication. This authentication is based on a three domain model (that is the 3-D in the name). The three domains are: *Acquirer Domain* (the merchant and the bank to which money is being paid), the *Issuer Domain* (the bank which issued the card being used) and finally the *Interoperability Domain* (the infrastructure provided by the credit card scheme to support the 3-D Secure protocol).

The protocol uses XML messages sent over SSL connections with client authentication (this ensures the authenticity of peers, the server and the client, using digital certificates).

4. The ideal e-commerce protocols

Researchers have identified a number of desirable characteristics that must be satisfied by e-commerce protocols:

- should ensure fair exchange,
- should not require manual dispute resolution in case of unfair behavior by one party,
- each party should be assured that the item he is about to receive is indeed the correct one,
- should not require the active involvement of an online trusted third party,
- should ensure anonymity for the customer and optionally for the merchant.

Fair exchange: Ideally fair exchange requires that either both the parties involved in the transaction receive each other's items or none do. However, researchers have often

used the term in a weaker sense: the protocol gathers enough evidence during execution so that, in case one party behaves unfairly and obtains the other's item. If a dispute occurs, a judge looks at the evidence and delivers his judgment. The dispute resolution is performed after the protocol execution, that is, after the customer has obtained his product or the merchant his money. However, such "after-the-fact" protection may be inadequate in an e-commerce environment where the customer and the merchant may be unreachable after the transaction.

Avoiding manual dispute resolution:

The need for manual dispute resolution, when one party behaves unfairly, does not arise if protocols provide *true fair exchange* – under all circumstances either both the parties receive each other's items or none do. Protocols providing true fair exchange typically use an online trusted third party. The third party receives the information from each party involved in the e-commerce transaction and then forwards it to the other party. As a result if any party misbehaves or prematurely quits, no harm is caused to the other party.

Ensuring correct item will be received:

Before exchanging the items, each party must have the confidence that the item he is about to receive from the other party will indeed be the correct one. The use of an online trusted third party helps to meet this requirement as well. Although using a trusted third party helps meet some requirements, the third party is a source of bottleneck for these protocols. Not only is the performance of the third party an issue, but also its vulnerability to denial of service attacks.

Reducing involvement of the third party: Several protocols have been proposed that do not use the third party unless a problem, such as, a party misbehaving or prematurely aborting, occurs. Such protocols are termed optimistic. Most of these protocols do not ensure true fair exchange.

No existing e-commerce protocol that we know of satisfies all of these requirements simultaneously. There are a lot of things to develop in the e-commerce protocols. This is why the research community works with de software companies to obtain the ideal protocol, accepted by all.

5. Protocol's Verification

In the analysis of conventional communication protocols, three kinds of techniques have been applied to this problem:

- *Inference-construction methods* are utilizing modal logics similar to those that have been developed for the analysis of the evolution of knowledge and belief in distributed systems. These methods are widely used and a number of specific problems are associated with them, related to: the analysis of zero knowledge protocols, the detection of parallel session multi-role flaws, the transformation of messages and prepositions to idealized messages, the fact that there is no complete semantics for the logic, and the modeling of freshness.
- *Attack-construction methods* construct probable attack sets based on the algebraic properties of the protocol's algorithms. These methods are targeted towards ensuring authentication, correctness, or security properties; they are not dependent on the correctness of a proposed logic. Their main disadvantage lies in the big number of possible events that must be examined and the exponential searches. They can be divided into three sub-categories based on their theoretical foundation: methods based on general purpose validation languages, algebraic simplification theoretic model methods and special purpose expert system, scenario based methods.
- *proof-construction methods* a recent approach, which has the potential of being as thorough as attack construction in finding possible attacks, while avoiding exponential searches by replacing them with theorems about these searches. It is complementary to inference-construction methods, since they are also based on the problem formalization through hypotheses and authentication properties, but rely on problem-specific properties and a specification at a finer level of precision.

The robustness principles are therefore helpful, in that adherence to them contribute to the simplicity of protocols and avoid a considerable number of published confusions and mistakes: be very clear about the security goals and assumptions; be clear about the purpose of encryption (secrecy, authenticity, etc.); do not assume that its use is synonymous with security, be careful that your protocol does not make some unexamined assumption about the properties of the underlying cryptographic algorithm; be sure to distinguish different protocol runs from each other; do not assume that a message you receive has only a particular form, even if you can check this; sign before encrypting; the identity should be mentioned explicitly in the message.

6. Trends

Several researchers believe that in the near future, more effort will be spent on designing secure protocols and less on formal verifications. As expected, this trend has received criticism similar in nature to that expressed towards the use of formal methods in program design and implementation.

Other researchers argues that design specifications do not guarantee that protocols will meet security goals that were not foreseen by the design approach, that the protocols designed are sometimes impractical, and that — due to the imprecision of design principles — flawed protocols may in any case be designed.

A protocol analysis toolkit-based can be described as follows:

- initially, use an inference-construction method, like BAN, to determine what the role of each message of a protocol should be and to ensure freshness properties;
- then, use an attack construction method, like NRL Protocol Analyzer, for finding simple attacks quickly;
- and finally, utilize a proof-construction method to investigate deeper properties with a modest amount of effort.

Furthermore, some areas where current research is conducted have emerged.

Another interesting research direction is the investigation of the potential integration of methods (like the NRL Protocol Analyzer) and the Interrogator model within the methodology of fail stop protocols in the cases of protocols that do not satisfy the fail-stop requirements. To ease and extend the use of these it would be useful to achieve automatic translation of a higher-level protocol specification language, using exhaustive finite-state analysis and formal logic methods.

The research community is also working towards developing tools that take easy-to-write specifications of protocols and the expected properties and quickly perform formal analyses checking for failures of these protocols to achieve their desired properties.

An interesting research trend lies in the fact that many current activities use formal methods for analyzing and verifying modern protocols and protocol suites to be used in the commercial world. These suites consist from a set of single protocols which interact with each other causing, previously unknown, potential vulnerability.

7. Conclusion

The research community, working towards developing more effective techniques to design protocols that are guaranteed to be reliable and correct in the first place, has implemented the synthesis approach. Most of the recent research in this area is focused on the application of the notion of channels in order to effectively implement the layered approach.

Researchers have identified a number of desirable properties of e-commerce protocols: should ensure fair exchange, should not require manual dispute resolution in case of unfair behavior by one party, each party should have the assurance that the item he is about to receive is the correct one, should not require the active involvement of a trusted third party.

These properties must be introduced in the next generation of e-commerce's protocols for having secure e-commerce world.

Knowledge Based Economy Strategies and Policies in Romania

Tocan Madalina Cristina
Ecological University of Bucharest
Mada_popa@yahoo.com

Abstract

In recent decades, knowledge is increasingly viewed more as a driving force of economic growth, which has generated a growing interest to information, technology and learning and their role in economic growth. Specialists consider that this new economy, knowledge-based economy, implies permanent products sold through virtual markets which determine much lower transaction costs and new business strategy is centered on exploiting niches. This type of economy is emerging in Romania and this paper aims to present the main national strategies and public policies for the development and implementation of information society knowledge economy in Romania

Key words: knowledge, knowledge based economy, strategy

J.E.L. classification: O29.

1. Introduction

Today, knowledge is seen as a driving force of economic growth, which generated a growing interest to information, technology and learning and their role in economic growth. "In the last few decades many of the most developed countries have moved from industrial economy to knowledge-based economy which is based on knowledge creation, information and innovation." Knowledge-based economy means constantly updated products, customized to the uniqueness in some cases, sold through virtual markets providing much lower transaction costs. Knowledge-based economy also means new business strategy, focusing on niches and exploiting economies of scale. Dynamics that take place at individual and business level determine changes to which governments are called upon to respond to

the application of legal and institutional frameworks as well as new policies with the use of specific incentives.

In this paper we adopted an approach to issues related to knowledge-based economy meant to underline the major facets of the phenomena analyzed: "A knowledge-based economy is the type of economy where the generation and exploitation of knowledge play a predominant role in national wealth creation. This implies the existence of several characteristic elements and processes of the knowledge economy:

- Knowledge- intensive production through continuous innovation;
- Efficient and effective dissemination of knowledge by all members of society.
- Intensive use of scientific knowledge in all areas (particularly in technology and business organization).
- Creation of flexible learning methods for this new type of economy, including various forms of public private and flexible partnerships, adapting systems to ensure continuous supply of work force to an economic system based on innovation and research;
- Implementation of government policies adapted to the new economic dynamics, policies supporting the creation and dissemination of knowledge, while avoiding distortions of market introduction, that the use of an appropriate mix of measures address both the present and future.

2. Knowledge based economy in Romania

This type of company is emerging in Romania, but Romania has yet to recover substantial backlogs in many socio-economic development sectors. The role of knowledge-

based economy vectors in this case must be carefully defined so that society's response to the dilemma of "Bread or Broadband" is one that maximizes the social utility on the medium and long term, with small short-term costs. Achieving this objective requires in-depth knowledge of economic and social environment, a commitment from policy makers, involvement and support from civil society, and programs consistent with elements of motivation and implementation of all social ladders.

Romania's government programs and strategies for the knowledge-based economy must be viewed from a multiple perspective; there are several categories of factors that make them.

The first category of factors is given by the correlation and structural harmonization of Romanian socio-economic development resulting from Romania's accession to the European Union. This scale requires strategies focused on knowledge-based economy correlated with:

- European strategies and programs- in this case the correlation with the Lisbon Strategy;
- National strategies and programs-in this case, harmonization with the National Development Plan for 2007-2013 is the dominant context;

A second category of factors is given by specific features related with the development and growth of the knowledge economy in Romania at the beginning of XXI century. They impose on the one hand:

- Accelerating the development of processes where there is lagging behind the European level and generally the developed countries;
- Broadening the spectrum of action, to focus on developing basic conditions, on developing the knowledge economy pillars: development of communication infrastructures; developing of processes to generate knowledge capital; developing human capital;
- Avoid adverse effects of multiple disparities that manifest in the Romanian society: between geographical regions, between rural and urban areas, between different categories of people (like income level, in terms of culture, etc.).

- Keeping alive the values of specificity and Romanian culture and civilization (the essential traditions);

As we can see from the above, the complexity of strategic issues for the development of knowledge economy in Romania is great and this is reflected in many policy documents and action plans have been developed in recent years.

In Romania has been decided, developed and launched in implementing the following strategies and programs that impact on the development of knowledge-based economy.

National Development Plan (NDP) 2007-2013 provides the strategic conception for the development and application of national and regional policies. This document sets out five priorities that should be considered at all levels: national, regional and local levels. Of these, two are particularly important for developing knowledge-based economy, namely [1]:

- Priority 1 - Enhancing economic competitiveness and development of knowledge-based economy;
- Priority 4 - Development of human resources, employment, social inclusion and strengthening administrative capacity.

The overall objective of Priority 1 - Enhancing economic competitiveness and development of knowledge-based economy is to increase the productivity of Romanian companies to reduce average productivity gaps with the Union. It seeks to achieve by 2015 the average productivity growth of approx. 5.5% annually, which will allow Romania to reach a level of approximately 55% of the EU. Associated with this general objective the following specific objectives were established:

- SME contribution to GDP growth by 20% by 2015;
- Increase the value of total R & D expenditure to 3% of GDP in 2015;
- Increasing the number of Internet users - business / population - from 52% / 19% in 2003 to 70% / 55% in 2015;
- Reduce primary energy intensity by 40% by 2015 compared with 2001.

Sub-priorities that will focus on the measures under this priority are:

- Increase competitiveness by improving market access for businesses, especially small and medium enterprises;
- Developing knowledge-based economy by promoting innovation and accelerating research and development of information society;
- Improving energy efficiency and use renewable energy.

Taking into account the Lisbon objective of stimulating innovation as a competitive basis for economic development through the National Development Plan 2007-2013 states that in Romania it is necessary:

- Incentive measures for the systematic application of innovation and technology transfer, including funding for research, product development and /or acquired companies;
- Encourage private R & D expenditures both directly through increased public spending for research and development and procurement of high technology, and indirectly, through actions such as hedge funds, indirect tax measures, campaigns, etc.;
- Start research projects and development infrastructure that will provide genuine public goods in the competitive development;
- Supporting the innovative capacity of firms;
- Protecting intellectual property and brand development and market promotion;
- Strengthen cooperation with universities and companies with research institutes;
- Promote the use of information technology;
- Extension of broadband networks;
- Developing and improving electronic public services through the deployment of e-government;
- Ensuring availability of services and educational resources on the Internet;
- Developing a safe and dynamic e-business, by increasing the number and extent of exploitation of e-business opportunities to companies in general and in particular by SMEs;
- Increasing security of electronic communications networks, the adoption of ICT solutions and promoting anti-fraud contribute to the development of smart cards, e-business environment, e-

government to better use by companies of information and communications technology environment.

The overall objective of the Priority 4 - Development of human resources, employment, social inclusion and strengthening administrative capacity development of human capital and increase its competitiveness on the labor market by ensuring equal opportunities for lifelong learning and developing a modern labor market, flexible and including who will lead, by 2015, the sustainable integration on the labor market of 900,000 people.

Another strategy with importance in the development of the knowledge based economy in Romania is Government Strategy for Informatization of Public Administration [2]. This strategy refers exclusively to those aspects of e-government and intended use of specific methods of information technology in modernizing public administration. The strategy covers the following categories of actions:

- Computerization designated to increase operational efficiency in the central and local government bodies;
- Computerization services were offered to citizens and businesses, which often involve the integration of services provided by central and local government;
- Provide access to information by end users of information technology services for government.

E-government project generally aims to reduce disparities between small and large communities in the use of information technology by facilitating access to new technologies for local public administration authorities in villages and small towns. Most authorities in small towns do not have a presence on the Internet or only a limited, static Web pages giving basic information without providing services to citizens. These communities lack the technical and economic capacity and human resources to take advantage of the possibilities and opportunities of e-government, even if any means have basic computer and Internet access. The project allows municipalities with insufficient resources to create an own web portal that can interact with citizens of those communities and make them available in real-time electronic services and provide

opportunities offered business environment to attract investment, or to interact with other institutions. The tools made available through the project, these communities could have an online presence with all the benefits that result from this.

Large local government institutions (ministries, other central authorities, county councils, mayors of large cities, etc.) began to develop e-government initiatives that allow interaction with citizens through electronic means.

National Strategy for Information Society development and implementation of knowledge-based economy

Strategies are the result of developments in strategic concept development related to the development of the knowledge economy in Romania. This development was that defining moment in 2001 during which the Ministry of Communications and Information Technology has released more than 20 pilot projects aimed at boosting the development of Information Society in Romania and has developed and launched in implementing three strategies[3]:

- National Strategy to promote the new economy and implementation of Information Society (approved by Government Decision 1440/2002);
- Romanian Government strategy to stimulate and support the development of communication sector in the period 2002-2012;
- ICT Strategy for Horizon 2025.

National strategy to promote implementation of the new economy and information society[4] was built on the eEurope + action plan. This strategy will be reviewed annually to update the projects targeted by new technological developments and European policy convergence plan eEurope2005 providing information society for all, with the eEurope + plan. Reaching the deadline of the eEurope 2005 Action Plan coincides with the time of revision of the Lisbon Strategy, aiming to reach Europe in 2010 the most dynamic and competitive knowledge-based economy. Renewed emphasis on growth and employment use. Based on revised strategy and the observation that, in Europe, information society since the "pilot phase" to the "range expansion" (due to advances in technology and the emergence of new actors) European Commission has

launched the i2010 strategy, a five-year strategy aimed at developing the digital economy. stands i2010 initiative "A European Information Society for growth and employment." In the i2010 initiative the European Commission proposes three priorities:

- Creating a single market and competitive information society;
- Increased investment in research on ICT by 80%, based on the finding that in this area, the EU invests only 80 Euros per capita compared to 350 in Japan and 400 in U.S.;
- Promoting an integrated European information society.

3. Conclusions

Romania's European and global context requires urgent need to increase economic competitiveness. It is well known that competitive advantage is no longer an economy currently based on products or services, the presence of natural resources or geographical or historical peculiarities. Today's competitive advantage is created through innovation, highly skilled workforce and extensive use of knowledge, in other words a knowledge-based economy (Knowledge Economy).

Romania's economy is still largely under the effect of industrial and agricultural era, promoting products and services that today are hardly compete on international markets and even domestically. For this reason it is necessary to stimulate the development of knowledge-based industries and European countries to eliminate disparities in its effort to innovation, using new information and communication technologies and increased public education on the new economy. Otherwise, the position of Romania in the EU will be characterized by major cost uncompetitiveness driven economy.

Stimulating knowledge-based economy in our country is the principal means of ensuring participation of the national economy on global markets, while the world prices of products will continue to decline. For this reason there must be a dynamic balance between international competition based on costs (lower wages, economic incentives, products and low value-added

services based on existing natural resources) and knowledge (high-skilled labor, research innovation, design, products and services with high added value).

Building the knowledge economy in Romania is still in its infancy, policies and programs currently prevailing in the specific concept, the precursor of the information society and the main progress made is related to the decision of building a knowledge-based economy in Romania.

Modern Approaches in Romanian Management - Knowledge Based Management

Tocan Madalina Cristina
Ecological University of Bucharest
mada_popa@yahoo.com

Abstract

The increasing globalization of business, leaner organizations, products and service convergence and vast development of technology implied that the issues of more efficient and effective operation of an organization's knowledge assets have become more important than ever before. Years ago Peter Drucker warned us that those who will wait until this challenge becomes a "hot" issue are likely to fall behind and perhaps never to recover. As Drucker has predicted, knowledge has become the key economic resource and the dominant source of competitive advantage today.

The main objective of this paper is to present the status of the knowledge management implementation in Romania, after the introductory part of the paper in which the concept of knowledge management is presented. Conclusions are presented at the end of the paper.

Key words: knowledge, knowledge management.

J.E.L. classification: M19

1. Introduction

Society has recognized the value of knowledge for centuries. Intellectual reflection on knowledge has been pursued for as long as records of human activities are available. For hundred of years, family members have passed off their commercial wisdom to their children, master craftsmen have painstakingly taught their trades to apprentices and workers have exchanged ideas and know-how on the job. However, the terminology of knowledge management

was not widely used until the middle of the nineties.

In the nineties, the characteristics of the business environment have changed. The increasing globalization of business, leaner organizations, products and service convergence and vast development of technology implied that the issues of more efficient and effective operation of an organization's knowledge assets have become more important than ever before. Years ago Peter Drucker warned us that those who will wait until this challenge becomes a "hot" issue are likely to fall behind and perhaps never to recover. As Drucker has predicted, knowledge has become the key economic resource and the dominant source of competitive advantage today.

The main objective of this paper is to present the status of the knowledge management implementation in Romania, after the introductory part of the paper in which the concept of knowledge management is presented. Conclusions are presented at the end of the paper.

2. Defining knowledge management

Based on the review of the literature presented by many academics and practitioners, it can be concluded that there is not yet a common consensus on the definition and concept of knowledge management despite a great deal of interest on the subject. Defining knowledge management is especially difficult, as different perspectives or schools of knowledge management can yield different dimensions and meanings. For example, management information systems researchers and practitioners tend to define knowledge management as an object that can be recognized and controlled in computer-based information systems. Management

researchers, on the other hand, address knowledge as processed based on individual and organizational competencies such as skills and know-how [1]. Thus, different perspectives on the concepts of knowledge can lead to different definitions of knowledge management.

The American Productivity & Quality Center considers that "Knowledge management is a business strategy, best practice transfer, personal learning, customer intelligence, intellectual asset management and innovation".

However, in the simplest term, knowledge management means exactly that: management of knowledge. It can be extended to management of organizational knowledge for creating business value and generating a competitive advantage. It consists of the processes required to effectively manage knowledge. It is a systematic, explicit and deliberate building, renewal and application of knowledge to maximize a firm's knowledge-related effectiveness and returns from its knowledge assets [2]. Knowledge management is essential for enterprises to determine where they are going and for organizational survival in the long run. It is a key requirement to future successful enterprises and is rapidly being recognized by firms to be of major strategic importance.

Salleh and Goh's [3] definition of knowledge management where it is a process of leveraging knowledge as means of achieving innovation in process and products/services, effective decision-making, and organizational adaptation to the market for creating business value and generating a competitive advantage to organizations.

Uit Beijerse [4] considers that "the knowledge management can be defined as a strategic orientated way of motivation and facilitation of the company's members engagement in the development and utilization of their cognitive capacities through the valorization of its information sources, experience and capabilities of its members".

The American Productivity & Quality Center considers that "Knowledge management is a business strategy, best practice transfer, personal learning, customer intelligence, intellectual asset management and innovation".

However, in the simplest term, knowledge management means exactly that: management of knowledge. It can be extended to management of organizational knowledge for creating business value and generating a competitive advantage. It consists of the processes required to effectively manage knowledge. It is a systematic, explicit and deliberate building, renewal and application of knowledge to maximize a firm's knowledge-related effectiveness and returns from its knowledge assets [2]. Knowledge management is essential for enterprises to determine where they are going and for organizational survival in the long run. It is a key requirement to future successful enterprises and is rapidly being recognized by firms to be of major strategic importance.

The essence of knowledge management is built on intellectual capital, which includes Human Capital, Social Capital and Corporate Capital. All three are essential components of Enterprise Knowledge. Human Capital it is made up of an individual's past, present and future. Each of us brings a unique set of characteristics and values from the past. These include expertise education and experience. Built on these characteristics and values from the past, they represent a set of capabilities and ways of seeing and living in the world (such as creativity and adaptability). Just as important as things from the past and skills of the present, we each have a future capacity and a particular potential for learning. Social Capital includes human and virtual networks, relationships and the interactions across these networks built on those relationships. Corporate Capital includes intellectual property, both formal and informal (e.g., patents, ideas, etc.), and corporate functional and organizational processes. It also includes all the data and information captured in corporate databases, all that has been made explicit.

Knowledge management can be viewed as a process for optimizing the effective application of intellectual capital to achieve organizational objectives. The knowledge management challenge is to discover and capture our tacit intellectual capital, share this capital through the Social Capital and leverage Corporate Capital (that which is visible or explicit). From another point of

view, knowledge management can be defined as a collection of disciplines, technologies and practices embedded in an information infrastructure that supports creation, sharing and leverage of intellectual assets – tangible and intangible – in an organization to achieve business goals. Or, knowledge management can be defined as simply the encouragement of people to share knowledge and ideas to create value-adding products and services.

Denning highlights that 'knowledge management might be seen as comprising multiple dimensions including knowledge strategy, communities of practice, help desks, knowledge bases, knowledge capture, knowledge storage, knowledge dissemination, knowledge taxonomies, quality assurance, authentication procedures, budget incentives, and knowledge measures'.

3. Knowledge management in Romania

If in Romania knowledge management is viewed by many the managers as a concept from many manuals of economics, things are different abroad. But years ago, even there, in the large corporations the need for effective management of knowledge was not fully understood.

To realize the importance of the concept without too many headaches, endless training and academic terms, Siemens executives have been faced with an unusual challenge: 60 top managers from the global telecommunications division were taken on a lake in Germany, supplied with logs, nails and string and asked to build rafts. Directors were challenged to achieve their goal without changing a word between them. The exercise demonstrated how important is the team work and the communication of knowledge within a company.

In Romania, knowledge management has entered in the companies with the infusion of know-how received from the multinational companies and Romanian managers were not asked to build rafts. Knowledge management exists in organizations from decades ago and took the form of discussions among colleagues or training. But now the concept is applied in a formally organized with the aid of specialized departments and IT systems. "In Romania, at present, we are not fully aware of the contribution to the development of knowledge management organization. Its

principles are not known to the Romanian economy and there are enough experts in the field," said Octavian Serban, the head of the KM Institute Romania.

At Siemens Romania, knowledge management system has been developed as a new project, but was picked up globally. Its operating costs locally amounted to tens of thousands of dollars a year. In Siemens Romania, each new employee immediately enters into contact with knowledge management. It is, for example, automatically recorded in some databases and according to their position, receives regular information. On the other hand, the employee adds whenever new information is needed in the system.

Romanian Commercial Bank was one of the first local companies that have implemented a knowledge management system, establishing even a department specialized in this respect, in August 2004, and a corporate university, a year later. The BCR has implemented a system of electronic access to all internal rules to all employees of the bank and they were alerted in real time of any change of rules or procedures. Knowledge captured from professional events are accessible to employees BCR clearly defined areas. "Given that knowledge management operates with intangible assets, unfortunately, the world is not yet sufficiently to developed systems and tools to measure the value of this activity," said Executive Director of Knowledge Management Unit of the BCR.

At Arcelor Mittal Corporation, which owns major steel centers in Romania, the start of knowledge management programs has been made since the early '90s. Back then, Lakshmi Mittal arranged meetings between CEOs. Gradually, they became operational meetings focused on specific aspects of the production process after several stages of preparation. In 2004, Mittal has officially launched the Knowledge Management Programme. "Given that we have about 15 meetings each year KMP, each gathering 40 participants, program costs amounted to several million Euros per year. These costs are, however, recovered well, given that the rate ROI is about 20:1" says the General Manager of Arcelor Mittal.

The results of the knowledge management system implementation in Romanian Ensign

Management Consulting firm costed around 160,000 Euros, and the results were immediate. "Increased efficiency consultants accessing faster because of the knowledge and skills have been developed to capture, dissemination and use of the information. A low time of integration of newcomers," said Roxana Blat, consultant at Ensign Management Consulting firm. A major component of cost is infrastructure, including creating the network, hardware, software and portable equipment or the office.

Ness Romania is one of the few local companies that offer solutions for information management. "For KM, IT is one area that comes with new tools, resulting in software applications that can provide clear competitive advantages to those who use them successfully," said Liliana Muraru Ness Romania marketing manager.

The vice president of human resources within the Vodafone Romania says that the purpose of knowledge management is to improve decision-making processes to integrate and reintegrate company's experiences, to increase the number of innovations to transform information into knowledge and obtain new knowledge. The advantages of such approach are obvious. Shared experiences and the knowledge of colleagues help others to combine as much information to find a creative solution or more importantly, innovative. "There are few situations in which employees of companies in various departments had to reinvent the wheel just because they were denied access to certain information, colleagues from other departments that already had them, but not of others had made known, draws Vodafone official attention. In the telecommunications industry, pressure is among the biggest change and innovation is essential to stay in the game. Vodafone provides its employees with database projects undertaken by colleagues in other countries, information on legislation, local and international press articles and forums on various topics and personalized. Over time, the company has undertaken several projects aimed at stimulating innovation and encouraging employees. Each employee may submit his idea for a new service / product / procedure / process or to improve existing ones and that he recognized the contribution when the idea is transformed into a viable project.

Involvement is the key word and Tuborg Romania. At Tuborg they are trying to attract as many people in various projects and they believe that the management is very important for each contribution, regardless of the department in which it operates. They designed the a program "Your idea counts", which encourages employees to provide solutions and suggestions, the best ideas with practicality being awarded. Tuborg Romania President considers that: "An employee with experience working on projects faced with all aspects of business and acquired over time an overview of the whole activity, which helps it effectively manage any situation. It is important that the project results to be implemented. Employees must feel the importance of their role and see the results. The changes involved in the organization this new paradigm are not easy, and project management and cross-functional teams can be difficult to implement. However, practitioners and researchers in the field ensure that the results worth all the efforts of a company that wishes to remain or to become a market leader.

Creativity and innovation is that "something" that distinguishes between companies and managers are aware of this. At the national level, except for textile and footwear industries, Romania is in all cases lower than the size of the innovative process of corresponding sectors in the EU. This leads to the conclusion that accelerated innovation is needed to eliminate disparities in growth and technological dependence.

The latest data on the level of innovation in Romania is based on statistical research findings on innovation activity for the period 2004-2006, harmonized survey Community Survey 4 CIS (Community Innovation Survey). According to survey results:

- The share of innovative enterprises in the period 2004-2006 is around 20%, showing improving economic growth climate in our country. Share of innovative enterprises is close to the EU average over the many countries in transition to knowledge-based economy.
- Structure of innovation expenditure is directed mainly towards the purchase of machinery, which means that much of the innovation process was actually based on technological catching

- The innovative firms-67% had both product innovation and process, 9% had only product innovations and 24% had only process innovations.
- The industry is more innovative than the firms in services. Of all enterprises are innovative industries 22%, while the percentage of innovative enterprises in the services sector is 17%.
- Of all innovative companies, 19% said that they achieve innovation through cooperation. Cooperation in innovation requires active participation in research and development or innovation together with other companies or organizations in the country or abroad.
- The main effects of innovation are improving the quality of goods or services and increase production capacity. 37% of innovative enterprises mentioned as the main effect of improving the quality of goods or services, 32% mentioned increased production capacity and only 18% mentioned that the main effect of reducing the negative environmental impact and increasing health and safety aspects. Information used to support the innovation process was mainly obtained from company personnel and business partners.
- With a higher share than in the EU, leading innovators are small (the share of small innovative enterprises is 55% of the total, compared to only 14% for large enterprises and 31% for medium).

4. Conclusions

The European and global context requires to Romania urgent necessity to increase economic competitiveness. It is well known that competitive advantage of an economy is no longer currently based on products or services, the presence of natural resources or geographical or historical peculiarities. Today's competitive advantage is created through innovation, highly skilled workforce and extensive use of knowledge.

Romania's economy is still largely under the effect of industrial and agricultural era, promoter of products and services that today are hard to compete in international markets and even domestically. For this reason it is necessary to stimulate the development of industries based on knowledge and elimination of gaps comparing with European countries, through the efforts of innovation, using new information and communication technologies.

Unfortunately in Romania, knowledge management is in a very early stage and till now it has entered in the domestic corporations with the infusion of know-how received from the multinational companies. But the forecasts are encouraging taking into account the governmental strategies for developing the knowledge based economy in Romania.

The Promotion of Quality Culture in the European Union Space

Todoruț Amalia-Venera

Cîrnu Doru

Chirtoc Irina-Elena

„Constantin Brâncuși” University of Târgu-Jiu

amalia_venera@yahoo.com

Abstract

Quality is considered to be the key of competitiveness in the European Union space. The European economy confronts in this period, with a business environment entirely new, as a result of globalization and of technological progresses on the background of a profound economic crisis. The main objective of all the actors on the European economic market has to be represented by the competitiveness development, as an essential way to improve the standards concerning the life quality, in the conditions of functioning on the markets opened to the international competition. Proceeding in this way, the society will promote the economic growth, will create new jobs, will develop the social cohesion and will protect the ambient environment. Communication represents the way in which the new vision of European quality will contribute to the development of Europe's competitiveness, as well as the roles of different partners involved in the accomplishment of this goal.

Key words: quality, competitiveness, efficiency, management, culture, vision.

J.E.L. classification: M10

1. The promotion of European Quality

According to the European Commission the European politics of promoting the quality is a politics of sensitizing awareness of the decision factors with the purpose of obtaining the transparency and the political support necessary for the assembly of instruments, methods and techniques of quality management as well as for the

assembly of initiatives and pro-quality actions from the whole Europe.

The main objective of the European politics of quality promotion in the conception of the accomplishment of some specific actions oriented to the economic agents and to the public authorities from Europe, in the view of facilitating and stimulating them to obtain the excellence of their internal organization, the excellence of their results [1].

The specific objective is the establishment and maintenance of an adequate economic environment to the appearance and development of some synergic actions, reciprocally advantageous among the involved actors: enterprises, organizations specialized in activities specific to the management of quality, other interested organizations.

In the European Union space quality is considered the key of competitiveness and a vast campaign of formatting real culture of quality take place.

This focuses on the following aspects [2]:

- the accomplishment of a common infrastructure in the domain of quality;
- the spreading of a great volume of information from the domain of quality with a view to strengthening the unique European market;
- the Europeanizing of enterprises through promoting a European politics of quality.

The enterprises actions in a national framework but harmonized with the European standards. The European politics of quality is a transcendental politics of all the national politics it determines and influences; - the elaboration of some documents of the European Union, as well as "The European Politics of Quality Promotion", "The Way of Europe to Excellence", "The European Program for Quality Promotion", all these foreseeing some measures for the

accomplishment of a strategic vision of quality in all the member countries and for the identification of the key points of this approach of maximum importance.

The beginning in the European culture formation is represented by "The European Paper of Quality" which was signed at the end of the European Convention of Quality by the representatives of more European organizations in the domain of quality, which made an important step to the harmonization of approaches in the domain of quality [3].

The signatories of this document assume their responsibility for the following domains: to promote a general approach concerning the quality in business and the public sector; to develop the teaching of quality at all the levels of education; to develop the current way of thinking over the methods and instruments and to make them more accessible for everyone; to participate actively at the dissemination of quality experience; to promote the image of European quality worldwide; to be involved in the European Week of Quality, with the view to report over the realized activities, the current initiatives and future projects, over the implementation of the management system of quality and its certification in accordance with ISO 9001/2000.

According "The European Paper of Quality", quality is: an objective of the organizational excellence is a methodology, a priority, a measure of efficiency, an action force of competitiveness.

Thus, quality is an objective because, to be competitive, the organizations have to respond precisely to the clients and user necessities and expectations. But, the quality is also a methodology which promotes the participation, the entire and responsible involvement of each person and at the same time the development of an adequate environment of work.

Quality becomes simultaneously an action force of competitiveness by lowering the costs, the beginning of people's imagination, the promotion of innovation, the renewal of the organization, the encouraging of the initiatives and consequently the increasing of jobs.

The economic competition always asks the organizations to do their best, and the quality has to be a priority for everyone every time.

Quality connects all the economic and social actors in a chain of quality, in which quality concerns everyone and asks to each and every person to be involved.

To realize this entire involvement which is a condition of the future progress, the public authorities, the professional and consulting organizations decided to sign "The European Paper of Quality" which forces them to action.

The signatories assume their responsibility in the following domains:

- to promote a general approach concerning the quality in business and public sector;
- to develop the teaching of quality at all the levels of education from the elementary to the superior education;
- to develop the current way of thinking over the methods and instruments and to make them more accessible for everyone;
- to participate actively at the dissemination of quality experience;
- to promote the image of European quality worldwide;
- to do their best to realize new progress in quality during the year;
- to be involved in the European Week of Quality with the view to report over the realized activities, the current initiatives and the future projects;
- the implementation of the management system of quality and its certification in accordance with ISO 9001/2000.

Thus the quality determines the maintenance of the organization on the market, its recognition on the intern and international plan, the growth of products and services competitiveness offered to the clients.

The European Federation of the Quality Management (EFQM) promotes a series of integrator concepts contributing to the crystallization of European culture of quality.

Thus the orientation to the results supposes "that the appreciation of an organization's quality depends on the satisfaction of all the parts interested from the financial point of view: clients, employees, providers, civil society, shareholders and physical or juridical people" [4].

Leadership and the goal's constancy determined the clarity of objectives and create an environment in which the

organization and the employees reach the excellence.

The Management, through processes and facts, another concept promoted on the European plan consists of the coordination of all the activities within an organization connected directly to the quality improvement based on reliable information.

The Implementation of staff can reach the maximum level when there are common values and an adequate culture for the participation of each employee to the improvement of quality.

Training – innovation – long-term improvement represents the base of an adequate culture formation, which determines the maximization of its performances.

The Development of partnerships supposes the existence and maintenance of some relations reciprocally advantageous based on trust with the business partners.

Public Responsibility then, when an ethical approach is adopted and when the overfull filing of expectations and of existing rules within the community is followed, the long-term interests of an organization and of its staff are the best satisfied.

2. The vision of European quality in a new perspective

The vision is “an ideal to which the organization tends, materialized in a weak structured image of future created from institutions or desires” [5].

Therefore, vision is an image, a painting of the future to which one aspires. There are both individual visions of the organizations members and a common vision of them. An important vision has to be created, communicated, expected by everyone, because only on this background the actions can be planned and the people involved in their development.

A vision refers mainly to the business which will develop, to the established mission, to the relations which will develop and the organization’s capability.

Some companies adopted the word “*vision*”, understanding by this where they would like to be in the future or what they would like to realize.

A declaration over the vision they had could refer to: the obtaining of a product at the level of the most lowered cost of the producer, the obtaining of the leader position on the market, the obtaining of the leader of innovation or opinion position, the obtaining of the leader of the quality position. To form the vision, some information is necessary from various domains: about products, technologies, projects, people. The romantic conception thought it is the fruit of magic or divine grace. Generally though, the formation of vision is based on the past analysis, of present, of future, the analysis referring to people, equipments, knowledge, and business.

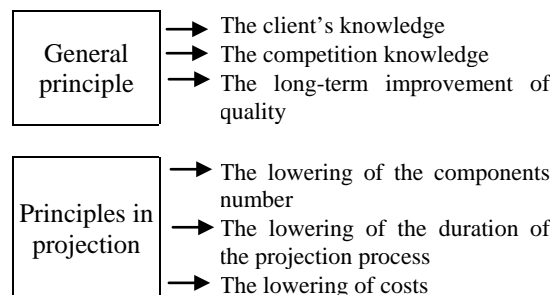

At the same time with the growth of vision’s importance, a new type of manager outlined, meaning the industrial leader. In contrast with the technocrats, the tension is directed to the creation of a unique vision in the enterprise, to communication and motivation. The vision’s sharing is done because of the same external restrictions – competition – and of some internal – new standards for products or for quality.

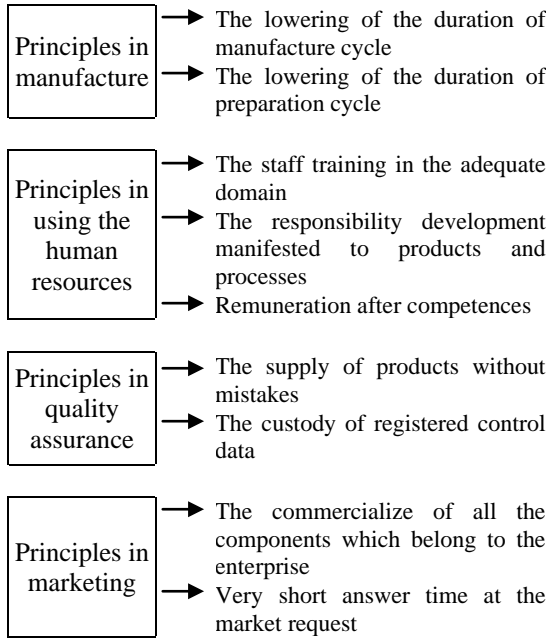

Always, a shared vision is not only an idea, even if there is about a fundamental idea, but an internal force, which gives energy to the employees.

To manage and enterprise not only a general vision is necessary, but also a vision over quality. The ruling vision a lot of important firms in the world have is that of “*world class manufacture*” (WCM) which allows the products to be better realized than any competitor, which supposes ability in manufacture.

At the background of WCM there are the following principles:

Figure1. The principles of WCM vision

To transform this vision in a plan an assessment of the present estate is necessary, the involvement of all the components contributes to the realization of production and of implementation, meaning the realization of projects and of all activities foreseen in the strategic plan.

The tendency to “*the world class manufacture*” comes with a vision in quality ensurance to “*World class quality*” – quality of world class.

This vision reflects in the way in which needs are perceived, in the attitude towards quality, in the expressing or manifesting of some components about quality. Also, the transaction to WCA supposes, mainly, a partnership adequate to the firm.

On the European plan a first strategic vision of quality has been defined for Europe in 1995. It emphasizes the importance of an image development of European culture and of a European culture of quality, in the view to favor the economic growth, to increase the jobs and to develop the world competitiveness of European enterprises.

It has to be noticed that this vision over the European quality also offers an image of the role of different involved public and private partners. The accomplishment of this vision necessities adequate action undertaken in two directions:

- an extern perspective – oriented to the clients’ satisfaction and the respecting and protection of the ambient environment;
- an intern perspective – destined to the ensurance of the accomplishment of different managerial and strategic functions, efficiently, and to the capitalization of the human potential.

The strategic vision for Europe includes the following aspects:

- citizens, consumers and clients are satisfied;
- the organizations’ staff is well-educated, trained, motivated and valuable;
- the enterprises are administered efficiently;
- the ambient environment is respected/ protected;
- the available resources are well-used;
- the unemployment is lowered through global competitiveness, innovation and creativity.

The ample analyses performed in the member states of the European Union emphasized that the level of the importance awareness and of the quality role is insufficient in these countries, as it can be seen in the following figure:

Table 1. The awareness of quality importance in world

Country /Region	The Role of Quality in Management	The level of the awareness of quality importance
Japan	Quality is an essential element of the global management of the organization.	Excellent
USA	Quality has a more and more important role.	Good
West Europe	Quality is considered to be a specialty professional problem of management.	Insufficient
Central and East Europe	Quality is considered to be only the problem of the employees from the directly productive compartments.	Limited

Other countries	Quality is perceived as being a secondary problem, not connected to management.	Lowered
-----------------	---	---------

Source : *A European politics of quality promotion for the improvement of the European competitiveness*, The European Commission, FRPC, 2001

Therefore the efforts intensified for the awareness of the quality role importance at a European level and in this way the ministers with responsibilities in the domain of public services in the member states of the EU decided – within a reunion at Vienna – to develop a common program of actions concerning the quality of public services.

Consequently, a lot of important actions have been initiated in this way: an examination has been organized to know the well practices in the domain, special work groups took place to compare the obtained performances in the domain in different member states of EU and an instrument based on auto-assessment has been introduced which allows the civil servants to assess the quality of their own activities and results.

The necessity of a new European vision over quality was imposed, new versions of it being elaborated. Thus, at the beginning of the millennium, the European quality confronts to a business environment entirely new, as a result of globalization and of technological results. This situation imposes new attitudes of the different involved partners. The economic agents need the improvement of their own managerial capacity, and the public administrations need to facilitate the creation of a favorable environment for the lasting development of a society.

The main objective of all the partners has to be represented by the competitiveness development, as an essential way of standards improvement concerning the life quality, in the conditions of functioning on markets opened to international competitiveness. Proceeding this way, the society will promote the economic growth, will create new jobs, will develop a social cohesion and will protect the ambient environment.

The European vision over quality has three fundamental elements – each element being developed structurally and argued by a team specially created – thus:

- we enrich through diversity;
- we build on our success background;
- we earn together.

The vision over the European quality, edition 2000, has the following content: „Europe is a space within which enterprises and public administrations refer to the accomplishment of excellence in what concerns their results and their internal organization, all these being in the society benefit, in its assembly”.

3. Conclusions

The vision over quality send a message in accordance to which all the actors of the economic and social life should assume and play their roles with the view to accomplish a better awareness of the quality importance for Europe, as well as to engage themselves in the accomplishment of the fundamental objectives established with the view to long-term improvement and to the client's satisfaction.

This pro-active approach needs a cooperative attitude and a spiritual opening from the involved economic agents for them to accept the existence of a general commitment from the public service in the sense of transforming them into authorities which impose the respecting of some compulsory conditions in “facilitators” and “moderators”.

Thus, the economic agents and the public authorities send the society a message in accordance to which the public and private partners adopted adequate strategies of quality, contributing together at the enrichment of the civil society and so, being worthy of its trust and investments.

Assessment Criteria for the University Scientific Research Projects

Toma Cristian Marius

*"Alexandru Ioan Cuza" University Iasi, Doctoral School of Economics,
"Gr. T. Popa" University of Medicine and Pharmacy Iasi*

tomamariuscristian@yahoo.com

Abstract

Scientific research is part of the university's mission, at least the major universities, being necessary to complement the learning process. The important universities consider that "the development of scientific research as a fundamental competence is essential for survival in a more and more competitive environment on global level and that is why, research should be part of the university mission".

This paper presents the results of a study which aimed to highlight the main assessment criteria used for the quality evaluation of university research projects. In the study there were involved 36 project managers from the National Plan of Research, Development and Innovation PN II 2007 – 2013. The managers of the research projects are university teachers who work for one of the three universities in Iasi: "Al. I. Cuza" University of Iasi, "Gr. T. Popa" University of Medicine and Pharmacy of Iasi and "Ghe. Asachi" Technical University of Iasi.

Key words: university scientific research projects, assessment criteria, project managers

J.E.L. classification: I 23

1. Introduction

The beginning of this century foresees many challenges for the mankind, questioning even the evolution and the existence of the mankind.

The changes in climate, the severe reduction in energetic resources, the increased average age of the population, the critical lack of food and water in a great number of areas in the world as well as other problems

related to the expansion of local and geographical conflicts represent major factors which cast doubt even on the human race.

Even though science and technology have had a spectacular evolution during the last 50 years, they have not answered to all the serious challenges mentioned above.

The economic and financial crisis during the last years has highlighted the fragility of the world economy and the lack of policies of global long-lasting development.

One recommendation made by the group of experts who propose a new policy of research in the economy based on knowledge is to allot 3% of the GDP for research and university education in a ratio of 1% for research and 2% for university education [1].

Scientific research means targeted and systematic search for the explanations to real or imaginary phenomena and processes, search for the solutions to current problems or issues specially created only to be solved or only proposed but which arise the interest and have importance in sciences or everyday life [2].

Scientific research is part of the university's mission, at least the major universities, as it represents the complementary element required by the learning process. A learning process based on engendering knowledge is much more valuable and competitive than a learning process which is reduced to a mere transfer of knowledge from the teacher to the students. The important universities consider that "the development of scientific research as a fundamental competence is essential for survival in a more and more competitive environment on global level and that is why, research should be part of the university mission" [3].

Excellency in universities and research centres represents an essential factor for the increase in competitiveness and efficiency in the allotment of funds.

The analysis undertaken regarding the university scientific research in Romania have proven the following [4]:

- Chronic lack of finances from public funds on short and average term, explained only partially by the recession and economic crisis after 2008;
- The competitive allotment of most available funds on projects which could be considered, in their great majority, important from the academic point of view, but having a few chances to be strategically synthesized on national level;
- Narrow applicability of the scientific research results, including innovations, in the field of real economic practice.

1.1. "Peer-review" evaluation systems

In the peer-review evaluation systems the assessment of the scientific research quality is done by expert advisory panels, the scientific output of the involved researchers is selectively analysed, only insofar as is relevant to a scientific research project proposed for financing. These evaluations constantly search for the correlation of the research plan proposed to be financed with a research project, taking into account the researchers' previous activity. These assessments are generally used by the financing agencies from the well-developed countries, where the scientific research follows the needs of the social and economic situation.

Decisions on funding research grants and scientific publications will depend to a large extent on the results of the peer review, as it contributes to the scientific reputation of the beneficiaries of grants / publications [5].

1.2. The National Science Foundation

The National Science Foundation (NSF) is an independent federal agency created by the American Congress in 1950, with the mission to encourage scientific progress, improve health, prosperity and welfare of the American people as well as secure national defense. With an annual budget of more than six billion dollars, the NSF supports approximately 20% from all the research receiving federal funds [6].

The scientific assessment of the projects proposed for funding is undertaken following different stages:

- intellectual merit
- broader impacts.

As regards the intellectual merit, there are considered the following issues:

- ◆ Degree of importance held by the proposed topic for the increase in knowledge and understanding within the field as well as for other fields;
- ◆ Experience of the researchers involved in the project and their readiness to successfully accomplish the project.
- ◆ The scientific impact of the research;
- ◆ The coherence of the research plan.

As regards the impact, there are considered the following:

- ◆ Contribution to the increase of knowledge and understanding, promoting teaching work at the same time;
- ◆ Wider participation of "under-represented" / "discriminated" groups;
- ◆ Increase infrastructure for education and research;
- ◆ Disseminate the results on a wide scale in order to increase understanding;
- ◆ Benefits brought to the society.

1.3. Scientific Council for Medicine

Sweden is one of the countries which gives special attention to research and development by allotting an important percentage from the GDP – 3,6 % from GDP [7].

The **aims** of the Scientific Council for Medicine established for the period 2005 - 2008 were the following [8]: determining a substantial increase of funds from the Swedish government research conducted in the field of medicine; promoting equality in chances; promoting the highest quality research.

Following the decision of the Scientific Council for Medicine from January 2007, the grants from the field of medicine have been assessed taking into account the following criteria, since 2008: project, feasibility, project management and project results.

The assessment regards quality more than quantity and it focusses on the relevant publications for the project under study. Other indicators of the research results and

their importance could be represented, for example, by the improvement on national and international level of the norms regarding treatment and diagnosis in medicine.

The evaluations are of peer-review type, in speciality panels.

1.4. Assessment criteria for university scientific research projects in Romania

The notion of quality indicator was introduced to include into the financing methodology used by universities a component with a stimulating and a corrective role.

This quality indicator – **IC6** [9], which focusses on the evaluation of the *performance level in university scientific research* has a complex structure and an estimation formula which is different from the other quality indicators described in the methodology. For the year 2009, CNFIS proposed that the percentage of 7% out of the total should be maintained for this indicator, in the situation when strategic directions at national and European level support the graduate cycles, as these study cycles are the direct beneficiaries of the university scientific research results.

In 2009 CNCSIS followed 5 general principles of performance evaluation in university scientific research, established and applied by CNCSIS, on the basis of the specific methodology:

1. The ability to collect funds for the scientific research activity - 25%
2. The ability to train the highly qualified human resources for the scientific research activity - 10%
3. Relevance and visibility of the results of the scientific research activity - 50%
4. Ability of the universities to conceive/develop innovating products and technologies for the business environment - 10%
5. Institutional capacity of universities to conduct and support scientific research performance - 5%.

The main criteria taken into account for the assessment of the university scientific research projects are the following (CNCSIS):

1. Scientific quality of the research project;
2. Human resources quality;

3. Implementation method of the research project;
4. How to use the resources of the research project;
5. Managerial skills of the project manager.

2. Material and method

The main purpose of the study is to evaluate the quality of university scientific research projects.

The hypotheses taken into account are the following:

1. The quality of the university scientific research projects and implicitly the results obtained after the carrying out of the projects is directly proportional to the scientific and managerial competence of the project managers.
2. The most important criterion for evaluation of university scientific research projects, which implicitly holds the greatest percentage is the scientific quality of the university scientific research projects.

Our study included a number of 36 project managers from the National Plan of Research, Development and Innovation PN II 2007 – 2013. The research project managers are university teachers from "Al. I. Cuza" University, "Gr. T. Popa" University of Medicine and Pharmacy and "Ghe. Asachi" Technical University, all from Iasi.

3. Results and discussions

The answers to the first question about the number of research projects subscribed in the competitions are presented in Table 1. The table shows that 34 project managers (94,44%) subscribed more than 4 projects in the national competitions of university research projects, a fact which proves that they have experience in writing scientific research projects.

Table 1 Number of research projects subscribed in competitions

Crt no	Number of subscribed projects	Number of project managers
1	1-3 projects	19
2	4-7 projects	15
3	8-12 projects	2
4	> 12 projects	0
	Total	36

The 36 project managers mentioned herein have subscribed 130 projects of university scientific research into different competitions. The scores they marked are shown in Figure no 1.

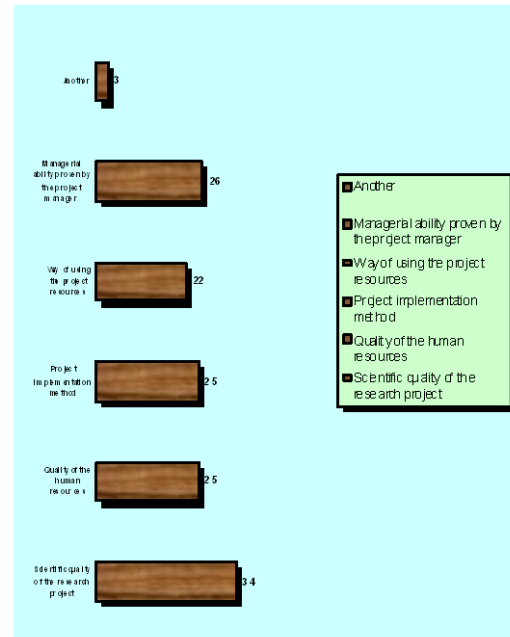

Figure 1. Scores of the university scientific research projects

The analysis of the first two questions of the questionnaire proves that 81 projects (62,30%) obtained a score higher than 90 points (the projects with this score have great chances to receive finances). Thus, the interviewed project managers build university scientific research projects which have real chances of funding.

As regards the assessment criteria which should be used for the evaluation of university scientific research project proposals, the answer can be seen in Figure 6. **The most important assessment criterion is the scientific quality of the research project** – 34 answers. On the second place lies the managerial ability proven by the project manager with 26 answers and on the third place there is the quality of the human resources and the project implementation method (25 answers). On the fourth place we find the way of using the project resources (22 answers).

Figure 2 Assessment criteria for the university scientific research project proposals

The answers given by the project managers referring to the percentage held by the assessment criteria are presented in Table 2.

Table 2 Percentages of the assessment criteria

%	Scientific quality of the research project	Quality of the human resources	Project implementation method	Way of using the project resources	Managerial ability proven by the project manager
0-20	2	22	33	35	32
21-30	11	11	3	1	3
31-40	10	2			1
41-50	6	1			
>50	7				

As it can be seen, **the most important criterion is the scientific quality of the project proposal** (23 managers considered that the percentage held by this criterion should be higher than 31%). The next one is the quality of the human resources (14 project managers – percentage higher than 21%). On the third place ranks the managerial ability proven by the project manager (4 project managers – percentage higher than 21%). The fourth criterion in the order of their percentage held at evaluation was considered the project implementation method and the lowest percentage should be

left for the way of using the project resources (0-20%).

The question about the aspects which certify the scientific quality of the research projects had the following answers (Figure 3):

- 32 (88,89%) out of the interviewed persons mentioned – originality and innovating character of the research project;
- 25 (69,5%) out of the interviewed persons mentioned – knowledge and adequate presentation of the up-to-date accomplishments in the field;
- 24 (66,7%) out of the interviewed persons mentioned – relevance of the research project objectives in the context of the researches in the field on national and international level ;
- 19 (52,7%) out of the interviewed persons mentioned – agreement between the chosen research methodology and project objectives;
- 10 (27,7%) out of the interviewed persons mentioned – interdisciplinary character.

Figure 3 Aspects which certify the scientific quality of the research projects

The question about the quality of the human resources involved in the university scientific research projects had the following answers (Figure 4):

- 28 (77,8%) out of the interviewed persons mentioned – scientific ability of the project manager;
- 26 (67,4%) out of the interviewed persons mentioned – quality and experience of the research team members;
- 24 (66,7%) out of the interviewed persons mentioned – managerial skills of the project manager;
- 14 (38,9%) out of the interviewed persons mentioned – involvement of the young researchers in the research projects;

Figure 4 Quality of the human resources involved in the research projects

The question referring to the aspects which certify the implementation method used for the university scientific research projects, responses were the following:

- 28 (77,8%) out of the interviewed persons mentioned – quality of the project management;
- 24 (66,7%) out of the interviewed persons mentioned – method of disseminating the project results;
- 20 (55,6%) out of the interviewed persons mentioned – project feasibility and credibility;

- 12 (33,4%) out of the interviewed persons mentioned – approach of the ethical problems arising in the project research.

4. Conclusions

The university scientific research project is the main piece in any competition for the granting of finances in a specific field.

After processing data from the questionnaire that we developed in this study which aimed the main assessment criteria used for the quality evaluation of university research projects, we concluded the following:

1. The first real problem in the building of a university scientific research project is the existence of a team of researchers. The research team should have an optimum number of members, in other words, overcrowding is useless and not allowed. There is also necessary the presence of a real scientific competence for each member of the project team.
2. The quality of the university scientific research projects and consequently the results obtained during the implementation of these projects is directly proportional to the scientific and managerial competence of the project managers.
3. The results of the study conducted reveals that the most important criterion for evaluation of university research projects, which has the largest share by default, is the scientific quality of university research project.
4. The research infrastructure represents a severe limitation in the building and implementation of university scientific research projects. A certain research infrastructure imposes a certain type of research projects. The change of research infrastructure requires important resources and it is slightly possible, under the conditions of the present day crisis, that they might be available in a short period of time.
5. The project managers who have scientific and managerial expertise know very well the criteria for evaluation and build research projects that have real opportunities for funding, its building

projects to win grants, not just to attend in competitions.

6. The project managers and the teams with a rich experience in building and implementing university scientific research projects have bigger chances to win and carry out this type of projects.
7. Research in universities, at a significant level, cannot be accomplished only by university teachers, if we realistically consider the fact they already have a full-time didactic activity or other activities which take up their time.

In order to increase the success rate in competitions, the organizing institutions, after the analysis of the already accomplished projects, of their results and real visibility of the potential users, should take the next step in the limitation of the closely related fields.

Abstract

Any university scientific research project is a complex work, with a mixed character, scientific and organizational, which requires professional as well as managerial competence. The conceiving and drafting of the university scientific research project must follow a set of rules which would ensure the basis for the carrying out of the project when it is financed.

This paper presents the results of a study which aimed to highlight the importance of building and developing university scientific research projects for the achievement of the proposed final results. The study we made included 36 project managers from the National Plan of Research, Development and Innovation PN II 2007 – 2013, project managers working in three universities from Iasi university center: "Al. I. Cuza" University, "Gr. T. Popa" University of Medicine and Pharmacy and "Ghe. Asachi" Technical University.

Key words: university scientific research projects, project building, scientific results

J.E.L. classification: I23

1. Introduction

It is common knowledge that the three pillars: Education, Research and Innovation, in the context of the existence of certain advanced systems of communication and information and knowledge processing represent important factors for the ensurance of competitiveness and cooperation in the

world process of social and economical development.

The universities are the catalyst of creation and they play a key role due to the position they have in society in providing the most important component of the knowledge based society: highly qualified human resource.

Due to the four major tasks that have: creation of new knowledge through research, knowledge transfer through education, dissemination through information and communication technologies and use knowledge in new products and services, universities are key players in the knowledge based society. Apart from education and research, universities have an important role in stimulating the economic development [1].

Scientific research in universities is an inseparable part of an efficient system of education and it is essential for the development of the university system in itself. Under the conditions in which the effects of the globalization are noticed in all social and economic sectors, scientific research represents an essential factor for the accomplishment of the globalization objectives. In this context, the role of the universities should gain strength and they should be regarded as real pillars of the society based on knowledge due to the following [2]:

- Acknowledgement of universites role in the education of human resources through the gathering of abilities, stimulation of the imagination and creativity for the development of the society;
- Make differences between the universities, taking into account the research performances, education, the transfer of knowledge and technology and making

available the services for the local and regional communities;

- Encouraging cooperation between different universities and between universities and research centres and economic organizations, in order to reach the critical mass which ensures a excellency in research and transfer of knowledges;
- Encouraging the innovating and entrepreneurial capacity, with professional management and leaders with vision, which could accomplish the objectives regarding quality and excellency;
- Attraction the most talented young people in powerful research centres and create all the conditions for their training and support.

The high-quality scientific research represents the engine of the society. Performance and quality in the research activity require an analysis of the human resources, of the research infrastructure and the method of resource use for the financing of the research projects.

The financing of scientific research undertaken in universities requires funds which can be obtained mostly by applying to competitions for university scientific research projects.

For the designation of the university scientific research projects which will be financed they have to be assessed and classified. The evaluation process must be a fair and transparent one in order to ensure the financing of the best university scientific research projects.

Any university scientific research project is a complex work, having a mixed character, scientific and organizational which requires professional as well as managerial skill. Building and drafting a university scientific research project should follow a series of rules which would provide the necessary information needed for the project evaluators, and the basis of the implementation when the project is financed.

A project is considered to be successfully accomplished if, on one hand, are complied with restrictions on time, cost and performance [3], and on the other hand, if the results proposed at the drafting time were achieved [4].

The main chapters taken into consideration when building and implementing a university scientific research project are the following [5]:

1. **The aim of the project** – represents the stage which the project team wishes to reach at the end of the project.
2. **The project objectives** – are the results desired by the team in order to achieve the aim or the steps needed to be taken to achieve the purpose. They describe one or several future stages of a particular system or product, considered to be desirable, necessary or accomplishable. An objective represents what is desired to be obtained following a particular action. These objectives should be: quantifiable, clear, precise, realistic, result-oriented.
3. **The project methodology** represents the chapter dedicated to the presentation of the way (how?) in which the project objectives will be accomplished, during a particular period of time (when?) The methodology includes the totality of procedures which will be used in order to accomplish the defined objectives.
4. **The project staff.** In order to justify the abilities of the research staff as required by the demands of the project manager, the project proposal should include a presentation of these persons, mentioning especially the qualifications and the skills detained at the moment of the proposal and their scientific papers which are directly related to the theme of the project under study.
5. **The research infrastructure** and the available facilities as well as the ones proposed to be purchased. Any applicant institution which proves to dispose of most facilities required for the proposed project should be considered a guarantee for the accomplishment of the project.
6. **The accomplishment plan of the project.** The working units of the project are its activities and stages. The scheduling of the project means defining the activities and arranging them in temporal succession so that the main events could be followed during the implementation of the project. The way in which the accomplishment plan is presented should allow the identification of the working periods, of the way in which the activities depend upon one other and of the involved partners.

7. **The project budget.** The value of the project informs the financier about the sum which should be paid in order to obtain the promised results in good time. The great quality of a project manager is to choose a research topic, employ a number of qualified researchers which could accomplish the objectives using the existent supplies, with only a few completions, during the established period of time and without surpassing the announced financing limit. The necessary budget is established after the previous chapters of the description have been drafted and explained.

The main chapters of the project budget are the following:

- Staff expenses;
- Material expenses (stationery, reactants, inventory objects);
- Mobility expenses;
- Expenses on the research infrastructure which needs to be upgraded;
- Dissemination expenses (publication, taxes of participation in scientific events);
- Expenses on third parties;
- Indirect expenses.

There must be taken into account the fact that any university scientific research project is built in a system of constraints. The project proposal conceived to obtain finances should know, from the very beginning, the particular system of constraints.

The constraints to which the scientific research projects are bound to are the following:

- ◆ Duration of the project;
- ◆ Maximum value of funds;
- ◆ The ambition of the proposed research theme;
- ◆ Number of members in the project research team;
- ◆ Scientific capacity of the research team;
- ◆ The research infrastructure of the institution which hosts the research project.

The scientific research projects address the scientific community or the economic or business environment, ending in a series of results which are published or transferred as

intellectual rights to the interested parties [6].

2. Material and method

The purpose of the study is to highlight the importance of the building and developing of university scientific research projects in order to obtain the proposed final results.

The undertaken study included a number of 36 research project managers from the National Plan of Research, Development and Innovation PN II 2007 – 2013. The research project managers are university teachers from three universities from the same university centre: "Al. I. Cuza" University, Iasi, "Gr. T. Popa" University of Medicine and Pharmacy Iași and "Ghe. Asachi" Technical University Iași.

3. Results and discussions

Each of the 36 scientific research project managers answered a questionnaire with 12 questions regarding different aspects related to the building and developing of university scientific research projects.

The answer to the first question about the number of projects subscribed to competitions is presented in Table 1. The table shows that 34 managers (94,44%) subscribed 4 projects in the national competitions of university scientific research projects, a fact which proves that they have experience in writing scientific research projects.

Table 1 Number of research projects subscribed to competitions

Cr t no.	Number of subscribed projects	Number of project managers
1	1-3 projects	19
2	4-7 projects	15
3	8-12 projects	2
4	> 12 projects	0
	Total	36

The 36 managers of university scientific research projects subscribed a total of 130 projects in different competitions. The scores obtained are presented in Figure 1.

Figure 1 Scores of the university research projects

The analysis of the first two questions of the questionnaire shows that 81 projects (62,30%) obtained a score higher than 90 points (the projects with these scores have great chances to obtain funds), as a consequence, the project managers build university scientific research projects with real chances to be financed.

The question about the way of using the university scientific research projects resources had the following answers:

- 34 (94,5%) of the questioned people mentioned – adequacy of the equipment and facilities necessary for the experiments, as well as the degree in which the equipment is available in the institution hosting the project;
- 20 (55,6%) of the questioned people mentioned – correct dimension of the chapters in the research project budget.

The scientific results obtained by the research project managers under study are shown in Figure 2.

Figure 2 Scientific articles obtained in the research projects

After the implementation of the research projects, there were subscribed 12 research projects in international competitions (FP5, FP6, FP7, etc.) and there were made 20 international collaborations.

The great number of articles published in ISI reviews, international data bases, B+ or B reviews, as well as the great number of articles presented at the international conferences created a good international visibility of the project managers and team members involved in the research projects. This fact helped to the creation of relationships with researchers from European Union countries, the USA and in collaboration there were subscribed research projects to European and international competitions.

The time dedicated to the accomplishment of the financial and accountancy stage of the research projects is shown in Figure 3.

Figure 3 Percentage of time dedicated to the financial and accountancy stage of the university research projects

As it can be seen from Figure 3, 27 managers (75 %) allot more than 20% of the time for the accomplishment of the financial and accountancy stage of the university scientific research projects.

The time dedicated to the conceiving and drafting of the scientific and financial reports is presented in Figure 4.

Figure 4 Percentage of time dedicated to the accomplishment of scientific and financial reports of the research projects

As it can be seen from Figure 4, 25 managers (71,5 %) dedicate more than 20% of the time allotted to the project for the accomplishment of the scientific and financial reports of the university scientific research projects.

During the implementation of the university scientific research projects there appeared several dysfunctional elements which generated pressure on the project managers.

One issue which casted great pressure and created numerous dysfunctional elements during the implementation of the research projects was the purchase stage of the projects. More than 90 % of the project managers expressed their discontent related to the stuffy laws which require a lot of time, a fact which led to delays in the developing of the projects (sometimes the project manager had to change the report deadline for one particular stage in order to make the purchases included in that particular stage).

Another important issue was also the motivation of the team members. In order to achieve the results they engaged into through the project proposal, the managers had to find different incentives for the team members, stimulating from the financial point of view, namely: salaries, fees and travel expenses to the conferences where the results of the project were presented.

The young researchers (Masters and PhD students) as members of the research teams proved to have an average interest in the carrying out of this type of research projects (certain projects required the involvement of 2-3 young researchers in the team, clearly describing their part in the project implementation).

The practical results of the undertaken research projects are presented in Figure 5. Unfortunately, this chapter has less eloquent results. It is hard nowadays to find a company which is willing to invest in the selling of a prototype or in an invention obtained as a result of a research project. The company should have serious financial resources and should also be positive that the production of the prototype or invention will bring profit.

In case of 29 managers (80,6%) the results of the research projects were used for new project proposals and this proves that there has been created a new direction of research (research group).

The feedback from the users of the project results, after 2-3 years from their completion was a moderate one – 12 (33,4%) project managers have reported this.

Figure 5 Practical results of the university scientific research projects

4. Conclusions

After processing data from the questionnaire that we developed in this study regarding the importance of construction and evaluation of university scientific research projects for the achievement of the proposed final results, we concluded the following:

1. The results of the university scientific research depend directly on the performances of the human resources and finances used for their accomplishment.
2. The results obtained in the undertaken research projects (ISI articles or included in international data bases, as well as articles presented in international conferences, prototypes, the development of new methods and investigation techniques) created a better visibility on international level of the project managers and team members of

the research projects. This fact also helped to make contacts between the researchers from the European Union countries, the USA and their collaboration led to new research projects subscribed to European and international competitions.

3. In case of 29 managers (80,6%) the results of the research projects were used for new project proposals and this proves that there has been created a new direction of research (research group).
4. The project managers and teams with rich experience in building and developing university scientific research projects have greater chances to undertake university scientific research projects.
5. In order to obtain the proposed results, the project managers had to offer to the project team members financial incentives such as salaries, fees and travel expenses for the national and international congresses and conferences to present the results of the research projects.
6. The university scientific research projects carried out in the Romanian universities have only a few results (prototypes, invention certificates, so on) which could be directly used in economy.
7. The feedback from the users of the project results is a moderate one and a small number of stakeholders show an interest in the project results after 2-3 years from their completion.

Fiscal Coordination vs. Fiscal Competition among Corporations in EU

Trandafir Adina
„Spiru Haret” University
atrandafir04@yahoo.com

Abstract

While tax harmonization in Europe can be difficult, fiscal coordination is as necessary as it is desirable. Tax competition, however, is the result of international mobility of tax bases, such as companies and financial assets. This mobility was not driven only by technological innovations in transport and telecommunications sectors, but especially the political decisions of liberalization and deregulation. This article addresses the issue of eliminating tax competition through tax base, by adopting CCCTB system, analyzing the benefits of tax coordination at European level. Fiscal Competition, in these conditions, would occur only at the tax rates that are so diverse (as it shows bellow) in the 27 EU Member States.

Key words: fiscal coordination, fiscal competition, corporate tax rate competition, common consolidated corporation tax base

J.E.L. classification: H32-Firm

1. Introduction

Since the establishment of the European Economic Community in 1957, there has been an ongoing debate on the need for cooperation and tax harmonization in Europe, debate has been intensified, mainly by creating the Economic and Monetary Union.

When the 1992 report issued by the Ruding Committee stressed the need to counter special tax regimes in force as their distortions due to the effects of internal market, Member States agreed on the need to remove these regimes, in order to maintain a basic balanced taxation and to prevent economic distortions. Indeed, most of these countries have been extremely focused on completing the single market and promoting intra-community trade, and not achieving

fiscal harmonization, not wanting to give up fiscal sovereignty in direct tax.

Since then, however, the process of harmonization in the field of direct taxation has been made by the EC Court of Justice, which in some years, has developed a considerable amount of cases, not only in direct taxation, but especially in Measures to support the income tax field.

Currently, the same Member States who have a long enough period was reluctant, urged the Commission to review the fiscal policy of state aid and make full use of its powers under the rules of the Treaty in the fight against tax competition harmful.

Consequently, the „Monti package”, adopted in 1997, whose main provision was the Code of conduct, did not address only those measures that affect or may affect significantly the location of a commercial activity in the Community, but had designed, also taking into account the provisions of the Treaty and related rules on state aid to combat harmful tax competition. In other words, Member States would retain sovereignty in adopting their tax systems, however, the Commission is now vested with the power to enforce state aid rules, namely art. 87, 88 and 89 of the EC Treaty, the tax rules set by those states in the field of direct taxation.

In simple terms, therefore, the Commission will examine whether the tax rules can be regarded as harmful or not, to the extent that they are opposed to free and fair competition rules, the fundamental principle underlying the state aid discipline.

2. Fiscal coordination in corporate tax system

In the late eighties a new concept of economic integration has been defined. Priority represent a mutual *coordination and close the tax systems* of Member States rather than a systematic approximation

imposed by the European Union. This new concept was developed in accordance with the principle of subsidiarity. In 1988, the Commission started to draft a proposal to harmonize the rules for determining the corporate tax base. Initial draft guidelines on depreciation allowances, capital gains, stocks, provisions relating to reserves, valuation adjustments, and overall costs. The main goal was to establish a more uniform tax treatment and more transparent in terms of corporate profits, which would open the way for a harmonization effort under the guidelines proposed directive in 1975.

In 1990, three proposals on company taxation were adopted

- The Parent-Subsidiary Directive dealing with the tax treatment of cross-border dividend payments between parent companies and subsidiaries and the taxation of parents on income received from subsidiaries.
- The Merger Directive aimed at the deferral of capital gains taxation in case of certain cross-border transactions related to the restructuring of groups of companies.
- The Convention on the elimination of double taxation with the adjustment of profits of associated enterprises.

The European Commission also published a draft Directive on the set-off of losses sustained by branches and subsidiaries (COM (84) 404 final) and a draft Directive on the abolition of withholding taxes on interest and royalty payments between parent companies and subsidiaries (COM (90) 571 final).

In addition to tax treaties, mutual assistance can currently be based on the Directive for mutual assistance in direct tax matters. This Directive provides for the exchange of information, response to inquiries, and the presence of an agent of one Member State on the territory of another Member State with a view to monitor the activities of multinational corporations.

Also, in March 1992, on the line of fiscal coordination in the EU, the Independent Committee of Experts on Company Taxation, chaired by Mr. Ruding, published a report containing conclusions and recommendations to company taxation within the EU aimed to ensure the proper functioning of the internal market after 1992. Also for fiscal coordination in line with the purpose of imposing discipline in this respect and the

elimination of harmful tax competition in November 1997, the Commission adopted the so-called "Monti package", which was a central proposal Code of Conduct (agreed by the ECOFIN Council meeting in December 1997).

In order to assess recent attempts to coordinate their fiscal policies in the EU, it is useful to remember the purpose of coordination: increased mobility of companies and financial assets as a result of liberalization, which led to increased tax competition within the EU. When the opening was created, European politicians "forgot" to design and architecture parallel tax. This event fundamentally changed the balance of power between governments and market players.

Currently, the European Commission and Member States are trying to regain the power they lost, but this seems to be extremely difficult. These processes can be studied in terms of "politics of scale", a paradigm that opposes neofunctionale theory. This paradigm is basically regional in assessing applications for greater fiscal autonomy in a context of economic and monetary union.

3. Fiscal competition in corporate tax rates and fiscal coordination in tax base

There are many differences in corporate tax systems operated by each Member State, including significant changes in tax rates and tax base. In addition to these differences exist, namely, differences in other aspects of income taxes. Following are the key characteristics of corporate tax systems in the European Union.

The tax rates presented in Table 1., differ significantly in the 27 EU Member States. The lowest nominal tax rate of 10% recorded in Bulgaria and Cyprus. This is followed by Ireland, at a rate of 12.5%, Latvia, Lithuania 15%, and Romania 16%. All these nominal rates below the EU 27, which is 22%. In contrast, the highest nominal rate of corporation tax, Malta lies 35% followed by France with 33.33%, Belgium 33% and Spain by 30%.

Table no. 1. Corporate income tax rates applied in the EU27

Member State	* Combined rate (%)	Nominal rate (%)
Austria	25	25
Belgium	33,99	33
Bulgaria	10	10
Cyprus	10	10
Czech Republic	19	19
Denmark	25	25
Estonia	21	21
Finland	26	26
France	33,33	33,33
Germany	29,8	15
Greece	23	23
Hungary	20,62	19
Ireland	12,5	12,5
Italy	27,5	27,5
Latvia	15	15
Lithuania	15	15
Luxembourg	28,59	21
Malta	35	35
Netherlands	25,5	25,5
Poland	19	19
Portugal	26,5	25
Romania	16	16
Slovakia	19	19
Slovenia	20	20
Spain	30	30
Sweden	26,3	26,3
United Kingdom	28	28
Average EU27	23	22

Source: Own elaboration from: http://ec.europa.eu/taxation_customs/taxinv, 2011
*) Combined share is made up of statutory rate, local rate and surcharges apply.

In Figure 1 are presented and compared the nominal rates and combined corporation tax rates in the EU27. Combined rates include near nominal rate, the central authority receiving the profit share percentage assigned to local authorities and certain surcharges. The biggest difference is recorded in Germany, from 15% as central authority to combined rate 29.8%, which includes 14% local incumbent. Also in Belgium are charged a 3% crisis surcharge that benefit only the central authorities, with a combined rate of 33.99%. In Hungary, the combined rate is 22.62% and includes, in addition to the nominal rate of 19% and 2% local rate. Luxembourg charge a combined

rate by 28.59%, which contains the nominal rate of 21% profit share of 7.5%, which applies in Luxembourg-City and a 4% solidarity surcharge to finance unemployment fund. Portugal, also, levy a local income tax rate of 1.5%, reaching a combined rate, above the EU 27 (which is, in this case, 23%), 26.5%.

Figure 1. Central authorities corporate tax rates and the combined rates in EU27

Source: Data from Table 1

Analyzing the evolution of the effective average tax rate (EATR, Average Effective Tax Rate) is, in fact, the relevant rate for the analysis of discrete investment choices, such as choosing the location. EATR is calculated for each of 15 different investment types - five assets, each could be funded from three sources. EATR is a measure of present value of taxes paid is expressed as a proportion of net present value of income stream, except the initial cost of investment), using the Devereux and Griffith (1999, 2003) methodology, Elschener and Vanborren (2009), have reached the following conclusions: EATR for the EU-27 average is 22.3%, but this hides considerable dispersion EATR levels of Member States. EATR lowest level recorded in Bulgaria (8, 8%) and highest in Germany (35.5%). In the EU15, EATR (26.3%) is considerably higher than in new EU Member States indicated that 12 (17.4%). There may be more reasons for variances between actual tax levels. One of them could be the size and the economic

development that can lead to higher levels TR for larger countries. For most countries EATR is slightly below the statutory tax rates. In some countries, EATR is higher than statutory tax rates. In Ireland, real estate taxes are very high compared to income taxes. France imposes a tax on business (*Taxe professionnelle*) for fixed assets. Cyprus applies a special tax on financial assets. Only in Belgium, Estonia and Italy, the average actual rates are considerably lower than the statutory tax rates. This is mainly due to a specific tax regime for financial assets or differences in tax treatment depending on funding. In Italy, local tax of 4.25% does not apply to financial assets, leading to a lower EATR. In Britain EATR reaches 29.3%, Spain 34.5%, Ireland 14.4% and 32.2% in Malta.

The Tax Base

The European Commission believes that the only way to systematically address the obstacles facing companies operating in more than one Member State in the Internal Market is to provide them with a consolidated tax base for their activities at EU level.

On March 16, 2011, the European Commission proposed a common system for calculating the tax base of corporations operating in the EU. Proposal for a common consolidated corporations tax base (CCCTB) would mean that companies could benefit from a "one-stop-shop" for filing tax returns and would be able to consolidate all profits and losses incurred by the throughout the EU. In this way, Member States could maintain full sovereign right to determine their own tax rates.

Common consolidated corporations tax base is a single set of rules that companies operating in the EU could use to calculate their taxable profits. In other words, a company or a qualified group of companies, should follow only one set of rules in calculating the taxable base, the EU, and not the different rules that apply in Member States where they operate.

In addition, using CCCTB, groups may submit a single consolidated tax declaration for the entire work in the EU and the consolidated group's taxable profits would be divided by individual companies through a simple formula, so that each Member State can tax then corporate profits with a tax rate they choose.

As regards depreciation, tax deduction for it, companies will choose CCCTB system will have to apply a set of rules for depreciation (25% over four years). The system will apply not CCCTB, as yet, is optional, as the depreciation will continue to apply national rules.

The CCCTB would be optional, allowing companies that felt that they would truly benefit from this harmonised system to opt-in, while other companies could continue to work within their national systems. This is a common sense approach, as it means that companies that have no intention of expanding beyond their national borders, and therefore will only ever work within one system, do not have to shift needlessly to a new tax system. The Commission also believes that a compulsory CCCTB would be out of line with the principle of subsidiarity, as it would mean that EU measures were being introduced to cover purely domestic, as well as EU-level, activity. Companies would have to opt-in to the CCCTB for a minimum of five years (to avoid them opting in and out for tax planning purposes). In addition, an annex to the proposal lists various criteria that a company must meet to be eligible for the CCCTB system (e.g. type of corporate tax rules that it must be currently covered by; type of company). Another crucial aspect of the CCCTB is consolidation, because it means that a company's cross-border activity within the EU will be fully recognised. In addition, consolidation would eliminate the need for the complex transfer pricing system that is currently in place for cross-border intra-group sales. Given that transfer pricing is one of the most burdensome and most expensive aspects of corporate taxation for enterprises, its elimination will lead to significant benefits for companies and groups within the EU.

Another positive aspect of the CCCTB is that it can make the EU a much more attractive market for foreign investors. For example, at the moment, companies operating in third countries such as the USA or China only have to deal with one national tax system. This is compared to a European system of 27 different sets of rules, which creates far more complexity and costs. A single set of rules for the corporate tax base, and a one-stop-shop system for filing tax returns, would make the EU a much easier

place for foreign firms to invest in. Many third countries have already indicated to the Commission that the CCCTB would help to make the EU a more interesting market for foreign investment.

4. Conclusions

Fiscal coordination is as necessary as it is desirable in the EU. The adoption by companies, which operate in more than one Member State, the CCCTB system, provides the following advantages both companies and tax policies at EU level:

- the CCCTB would make things far cheaper and simpler for businesses by creating one set of rules for calculating the tax base of a company or group, and by setting up a one-stop-shop system for filing tax returns.
- by allowing the consolidation of profits and losses at EU level, the CCCTB would enable the cross border activities of businesses to be fully taken into account and would avoid over taxation.
- for businesses operating cross border in the EU, the CCCTB unequivocally translates into savings in compliance time and costs. It is estimated that the current compliance costs could be reduced by 7%, which is equivalent to a saving of €0.7 billion across the EU.
- the CCCTB would be optional, allowing companies that felt that they would truly benefit from this harmonised system to opt-in, while other companies could continue to work within their national systems. This is a common sense approach, as it means that companies that have no intention of expanding beyond their national borders, and therefore will only ever work within one system, do not have to shift needlessly to a new tax system. The Commission also believes that a compulsory CCCTB would be out of line with the principle of subsidiarity, as it would mean that EU measures were being introduced to cover purely domestic, as well as EU-level, activity.
- the CCCTB opens up the possibility of expansion within the EU for SMEs that may, up to now, have thought it too costly and complicated to do so.

- overall, CCCTB offers better environment for research and innovation than foreseen in the current corporate tax systems of most Member States.
- the CCCTB also can make the EU a much more attractive market for foreign investors

In terms of tax competition, this is exacerbated by the tax base mobility. Establishing a common system for determining taxable income, tax competition in the EU will be at the level of rates of profits and there will be no hidden elements to distort the tax base and to emphasize the harmful effects of tax competition. And overall, states would retain sovereignty in setting their tax rates.

The Analysis of the Operational Efficiency

Trandafir Raluca Andreea
„Ovidius” University of Constanta
trandafirraluca@hotmail.com

Trucă Luiza Denisa
Academy of Economic Studies Bucharest
denitzsa@yahoo.com

Abstract

It is our goal to analyze the efficiency of the operations of one company by its technical endowment and its way of using the assets during the production cycle as to achieve basic operational efficiency, including the maximization of the results to the level when shareholders would want to get paid.

As an analysis method of the operational efficiency, we suggest the production cycle efficiency analysis (the operational cycle) in a structural way, respectively by tracking the analysis of the production phases. Even if the indicators are similar to those used by present models and established in banks, their contribution to the research will be achieved through the way of computing as its new formula is more fitted to our target (credit risk analysis). At the same time, we have suggested the analysis of some new indicators in order to improve the quality of credit risk analysis.

Key words: credit risk, ratio, performance.

J.E.L. classification: M 40, M41.

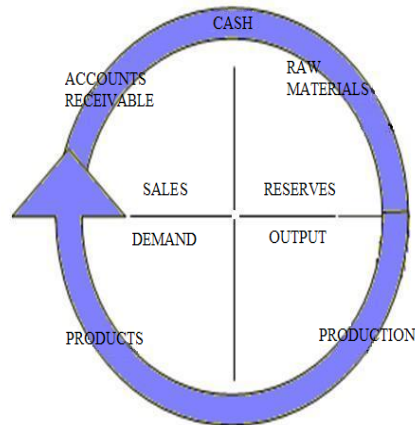

1. Introduction

The analysis of the financial reports and of the data required for credit scoring it will be concluded by applying some methods and analytical techniques in order to acquire useful information. These pieces of information are presented as being the important link between the data and the trends of these data, which point to the previous performances of the company and its present financial situation. The information will indicate the results or the consequences of the previous management decisions. Moreover, the information will be used in order to forecast the company's cash ratio, as cash ratio influences without a doubt the short-term solvency. In a next stage the long-term solvency establishment methods will be underlined.

2. The diagram of the efficiency of the operations

$$\begin{aligned} & \text{Demand \& Collection Period analysis} \\ \text{Collection Period} &= \frac{\text{Commercial accounts receivable} \times 365}{\text{Cost of goods sold (COGS)}} \\ \text{Period of stocking of finished products} &= \frac{\text{Finished products} \times 365}{\text{COGS}} \end{aligned}$$

$$\begin{aligned} & \text{Supply analysis} \\ \text{Raw Material Days} &= \frac{\text{Raw materials} \times 365}{\text{Cost of Goods Sold}} \\ \text{Debt owed to suppliers period} &= \frac{\text{Debt owed to suppliers} \times 365}{\text{Cost of Goods Sold}} \end{aligned}$$

Net Operating Assets (NOA)

The majority of daily activities financing are made through commercial credit (supplier) Costs can be minimized by having minimum stocks, fast cashing and suppliers' postponement of payment.

NOA's formula is =

$$\begin{aligned} & \text{Accounts receivable} \\ & + \text{Stocks} \\ & + \text{Prepaid expenses} \\ & - \text{Commercial suppliers} \\ & - \text{Accrued Expenses} \\ & = \text{Net Operating Assets} \end{aligned}$$

NOA can be used as a rate = $\frac{\text{NOA}}{\text{Sales in \%}}$

Production analysis

Turnover of ongoing production = $\frac{\text{Ongoing production} \times 365}{\text{Cost of Goods Sold}}$

Payback period = $\frac{\text{Direct production costs} \times 365}{\text{Cost of Goods Sold}}$

Net property plant & Equipment (NPP&E) turnover:
NPP&E turnover = $\frac{\text{sales in \%}}{\text{NPP\&E}}$

Lifespan rates of fixed assets involved in the production process

Expected lifespan

= $\frac{\text{Historical cost of fixed assets involved in production (FAIP)}}{\text{Yearly debt depreciation}}$

Elapsed lifespan = $\frac{\text{Acumulated depreciation of FAIP}}{\text{Yearly debt depreciation}}$

We will divide the turnover stocks period into several rates: Stocking period of raw materials, Turnover period of ongoing production and Stocking period of finished products. The superiority of this individual analysis is obvious. At the same time, it can be computed an assessment of the added value of the three indicators.

Net Property Plant & Equipment = the book value of land and other property, plant, and equipment (PPE) used in the production process.

The three rates of the lifespan rates of fixed assets involved in the production process (expected lifespan, elapsed lifespan and remaining lifespan) are not found for the time being as part of credit risk analysis. However, their examination is considered useful as it points out to the efficiency of fixed assets involvement in the production process, respectively the technical

endowment ratio and the necessity of an update (as for an application to an investement financing).

NOA – Net operating assets are a businesses operating assets minus its operating liabilities. Nowadays, credit scoring does not analyze this index.

NOA formula includes also a new indicator, Accrued Expenses. Accrued expenses represent the opposite of prepaid expenses. Expenses such as wages, interest and taxes are classical examples of accrued expenses.

As it concerns the service industry, the production cycle does not exist or it is short. This is why the occupancy rates analysis (for restaurants, hotels and medical clinics) is directly pointed at; obviously the occupancy rate is added to cash turnover, respectively the ratio between customers' payments and payment period.

Liquidity measurement analysis will be made through usual ratios (general and existing liquidity), even if they are limited by the presumption that all liabilities are going to be cashed in and all stocks can be sold.

As it concerns the question of uncertain or delayed liabilities in the credit risk analysis we suggest:

- the adjustment of liabilities with the values considered to be backlogs. At the same time we suggest to cut the unsaleable stocks from the stock value considered when calculating the general liquidity. Eventually, the degree of cashing the liabilities or the possibility of selling the stocks and to redo the calculation in reality can be adjusted by some percents.;

- use of new ratio

$$\text{Cash ratio} = \frac{\text{Cash} + \text{Shares that can be sold}}{\text{Current liabilities}}$$

Current liabilities

The analysis of forecasted liquidity is also crucial, the cash-flowing being its strong basis. Practically, the calculation of these indicators on analyzed periods is going to be inserted into the cash-flow which is prepared for the credit analysis.

Taking into consideration that the analysis of liquidity conversion cycle is very important to credit analysis, it will be added also to this stage. This indicator measures the length of the time period when the company has funds invested into working capital.

Liquidity conversion cycle = Operational cycle – Payment cycle

Operational cycle = Stock conversion period + Liabilities conversion period

Liabilities conversion period = The period necessary to liabilities to turn into cash

Payment cycle = The period of delaying the payments

If the cash conversion cycle is positive, the company requires short-term financing. Size of this funding is being given by **the turnover reported at 365 days * cash conversion cycle**. One achieves the same results through the relationship

Working Capital = Current Assets - Current Liabilities.

According to the report Current assets - current liabilities, the company will fall into 3 categories:

- **Moderate Attitude Company:** establishes a match between debt maturity and the life of the financed assets. Credit risk is minimized.

- **Aggressive Attitude Company:** the company chooses to finance their investments, even in part of assets. Credit risk achieves maximum peaks because the company is vulnerable to interest growth risk and could not refinance its credits from another lender (in the event of a conflict with the main bank). Greater attention should be paid to firms that choose this approach of liquidity management because short term borrowing is cheaper than a long-term and perhaps simpler to obtain so some companies are willing to sacrifice their safety and stability for the sake of higher profits.

- **Conservative Attitude Company:** the company chooses to finance its current investment activity in long-term debt. Risks are the lowest in this case.

The Assessment of the Founding Structure

Trandafir Raluca Andreea
„Ovidius” University of Constanta
trandafirraluca@hotmail.com

Trucă Luiza Denisa
Academy of Economic Studies Bucharest
denitzsa@yahoo.com

Abstract

For the analysis of structure will take into account, the need The need for short-term financing but also for long-term financing. It will be identified the finding sources and recomend financial structure including in the analysis of grafics on the evolution of economic structure on a reference period for the purpose of the funding. In order to reduce credit risk, equity analysis is recommended togeter with any loans from shareholder equity firm as well as analysis, that come to give answer to the question:- Choosing a funding strategy-offensive or defensive based loans on cash flow?

Key words: equity capital solvency, liquidity, patrimonial analysis, performance.

J.E.L. classification: M40, M41.

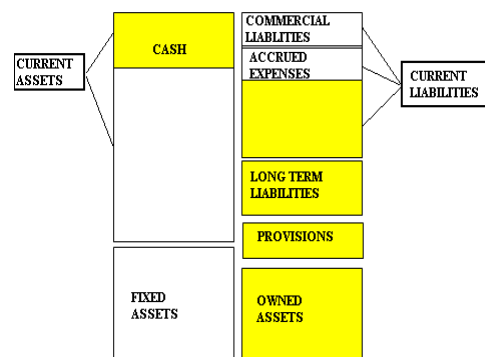

1. Introduction

In order to analyze assets the diagram below is going to show in the yellow spaces the values of areas affected by the company's decisions; here managers can act freely within the operational process and determine the size of non-operational funding necessary in order to achieve equality asset.

The need for short-term funding will be assessed through liquidity ratios.

The need for long-term funding will be assessed through solvency ratio.

Fig. no.1 - Company's balance sheet
(yellow areas are influenced by managers' decisions)

Sources of funding:

Given the founding needed, the company's management will choose the suitable type and proportion as: banking, capital or other (renegotiating contracts, shareholder loans, etc.) considering:
- not to pay for unnecessary financing (flexibility)

the achieved funding is always available(stability)

External sources of finance are debt and equity; domestic sources of financing are commercial loans, incurred but unpaid operating expenses and reported profit.

It is advisable to include in the analysis of the financing structure the graphs on the evolution of economic structure (separate graphs for the evolution of the assets structure, owned equity structure and evolution of liabilities structured as short and long-term). The assessment should be done over a reference period as it concerns the purpose of the funding analysis so that the differences from one period to another are relevant.

2. Analysis of solvency

The ability of an enterprise to generate enough cash to maintain its productive capacity and to settle with its due and long term liabilities.

Similarities and differences	Bank debts	Equity
Reimbursement obligation	X	
The source's payment	X contract Obligation	X at the right disposal of the shareholder's/company's decision
The value of the source's payment	Fixed	Variable, because of the uncertainty and risk taken, the payment can be highly significant. The cost paid by the company is higher than banking debts.
In case of dissolution	Prioritary	Only if all company's debts are covered
Short-term financing	X	
Long-term financing	X	X

3. Analysis of bank debt and equity

As it concerns doubtful or variable financial performances from one period to another, it is strongly advisable to lean more towards a funding through owner equity than through bank loans, because shareholders will be willing to take the risk (risk is proportional to their assumed reimbursement). Loan financing can be inaccessible from the beginning because of the risks that the bank already takes without a payment that compensates the risk (interest paid to the bank can not reward risks - considered to be high in these cases)

4. Analysis of debt and indebtedness

To mitigate credit risk, we recommend the equity analysis along with any loan offered by the company's shareholders. They are usually subordinated to the bank and can be incorporated in the calculation of indicators. However, if shareholders bring as funding the company only a small part of total sum needed, the risks that could affect the company will be borne mainly by the creditor. Furthermore, owners are those who control a company although they have invested less than the bank - the main financier.

Although there are a variety of ratios, based upon different assumptions or associations, the most representative calculations formulae of the solvency rates

The degree of leverage (Gearing) % = (Total Debt x100) /Equity

Where Total Debt represent all debts plus unused credits (loans approved and in use).

Lower rates of this value are preferable because, as this ratio is lower, so there is a higher protection against any losses suffered by the bank in case of bankruptcy. A high degree of indebtedness can encourage irresponsible behavior of the shareholders who bring small contributions of capital, meaning that they risk less and they can bear this loss, turning the business into a speculative one, financed by loans.

The choice that has been made can be backed up by the interdependence debt – equity ratio. The more cash generated is less certain, the more company depends on equity. Reduced values of this indicator ensure the long term survival. The company's gearing ratio should be compared to other companies' ratios or to other values in the area considered good for the industry where the credited company operates into.

It's recommended that a variation of this rate is more useful to consider:

Net gearing ratio% = $[\text{Total Debt} - (\text{cash} + \text{shares that can be sold}) \times 100] / \text{Equity}$

Where Total Debt represent all debts plus unused credits (loans approved and ready to use)

Also the degree of indebtedness (leverage) is going to be determined upon a modified formula of an in use one (Debt / Total Assets). Therefore here it is an adjusted indicator.

Tangible leverage = $\text{Total Debt} / \text{Own equity} - \text{intangible assets}$

We start from the fact that, when running a company, intangible assets such as formation expenses, trademarks, property rights, goodwill, etc. lose their market value and decrease the value of the amount of capital with the value they are currently registered in.

It's also important to consider the inclusion of off-balance sheet debt, respectively the contingent liabilities (the guarantees offered by the borrower as a guarantor, guarantees as corporate letters of guarantee, etc.. so-called "contingent liabilities." (IAS 37). Since not all contingent liabilities are achievable too and in order not to overestimate the degree of indebtedness, it should be considered a selection of contingent liabilities by:

- likelihood to influence the company under assessment during the grant period;
- the likelihood that the guaranteed company should not discount its own transactions and to act upon its guarantors.

Leverage –including contingent liabilities= $(\text{Total debt} + \text{contingent liabilities}) /$

Owned equity - Intangible assets

Total debt - total debt may include both the company's debts and the unused credit Another measure to assess capital structure is debt index from total assets, meaning how many of the assets of a company are financed by debts: **Debts / assets (leverage)**

5. Employed capital analysis

The purpose of this section is to verify the stability of a company in terms of available funding. Therefore Capital Employed ratio is defined as = Short-term bank debts + long-term bank debts+ Other long term liabilities + long-term provisions + social capital and we compute the debt ratio into the capital employed - information that shows the size of the risk faced by a firm = $\text{Total Debt} / \text{Capital employed}$.

It must be emphasized that the taking into consideration of the capital is taken at market value and not at the book value, as it concerns the possibilities for refining the calculation of rates. By comparing the market value of a company with its debt level, we can obtain a better solvency analysis of the analyzed company.

The proposed solvency ratios use new formulae for calculating the gearing ratio of the company and will indicate whether gearing level has equilibrium values despite the risks induced by the respective debt.

Financing a business by loan is cheaper than through capital, because:

1. Lenders require a much smaller share of profits than shareholders. Debt-financed investments have a lower risk than investment financed by shareholders because the latter want to cash dividends to be at least at the level of interest given by banks and depositors. On the other hand self-financing means lower risks on behalf of the company.
2. A profitable business generates a lower borrowing cost than the cost of owned equity, because operating profit is reduced along with income tax, which is a deductible expense in financial terms.
3. The costs of attracting new lenders are generally lower than those for the issuing of new shares

Also, because credits usually generate fixed costs regarding the interest, they limit the financing costs and create the required conditions so that the leverage effect could be used in the benefit of the company. The

Bank plays a major role in the economy, filtering the financings only to reliable, income-generating and responsible money-spender companies.

There are some positive aspects of financing a company by credit, although some companies decline risk-taking and tend to avoid high levels of external financing because the interest should be paid to financial creditors regardless the cash flow of the business. If the company has problems related to operational activity, consequently it should have problems concerning the payment of its non-financial creditors, shareholders, financial creditors, etc.. The basic idea of financial leverage is as follows: if the company earns a large profit, shareholders usually ask dividends out of the remaining profit after loan repayment. If the profit is small, creditors must be paid, and capital owners can not ask for dividends.

The inability of the company to pay the interest as it was established by the credit agreement, can generate its financial inability; the bank can block access to the accounts (even if only temporarily sometimes). This is the condition under which a firm can take decisions under time pressure to meet its legal obligations to creditors. These decisions may not meet the interests of business owners.

In practice, there is a trend for firms in certain industrial areas to use in a greater extent than debt financing rather than self-financing. The structural differences of the equity between different industries are the main factor that influences the type of financing:

Industries that rely more on research and development of new products and technologies (pharmaceutical companies) tend to have a lower degree of debt financing of their assets than companies that are not based on research and development.

Industries that require retrofitting (for example, firms producing footwear) tend to have lower levels of these indicators

It is also interesting to note the level of debt ratios in the industry. For example, the electricity industry has is a higher level of this index than in the beverage industry. There is variation even within this industry. The question is: why some industries tend to have a higher level of debt than others. A possible answer would be that they depend

on the role of financial leverage, on risk and level of taxation of profits.

At the end of the economic analysis of the assets, the study of the seasonal borrowing should be point at, too. Most of the times, the indebtedness level may be different during the analyzed periods. The calculation of the highest leverage can not be done without additional information given by the client (which could be hidden by himself). We propose in this situation the analysis of a new indicator that will prove the existence of seasonal fluctuations of leverage.

The rate of the banking system interest or from the audit report submitted by the customer is to be compared to the annual interest expenditures reported to the company's bank loans during the analyzed period

Rd versus annual expenses concerning the interest within year 1 * 100 weighted arithmetic average, depending on the actual use of credit during the reported year. The magnitude of reported differences will indicate the seasonality scale of a business gross financing.

In order to summarize, the ratios proposed for analyzing the structure of financing are:

The assessment of the financing scheme/Ratios suggested to be analyzed:
Net debt (leasing included)
Senior Debt/EBITDA
NFD/EBITDA
The degree of covering the interest liabilities EBIT/ Interest liabilities (LINE IS BEING REIMBURSED CURRENT ACTIVITY)
EBITDA cover
Gearing (Net Debt/Equity)
Gearing (Total Debts including the neutralized part of the line /Equity) - suggested indicator
Net gearing (Total debt-Cash Equity) % - suggested indicator
Leverage (Debts/Total Assets)
Tangible leverage (Total Debts /(Owner capital -Intangible assets) – suggested indicator
Leverage included contingent liabilities (Total Debt + Contingent liabilities) / (Owned Equity -Intangible Assets) suggested indicator
Equity in use ratio = Total Debt / Equity in use – suggested indicator

By analyzing the efficiency of operational and financing structure, a few basic and general directions related to reducing credit risk are emerging:

Increasing the rotation speed of the economic asset by increasing the rotation of all assets and by increasing the share of current assets, which can be restored more quickly by mean of turnover.

Increasing the volume of economic activity leading to a higher turnover and to achieve superior business returns.

Increasing the production's turning to account by promoting an active policy of marketing to achieve better market positioning.

Establishing an appropriate financial structure so that a higher leverage would trigger a higher level of profitability and economic growth in time.

The continuous tracking of the level of economic performance, whose dynamics should distance itself more and more of the cost of borrowed capital in order to decrease the possibility of financial risk and its consequences.

The choice of financing strategy (offensive based upon loans or defensive based on self-financing) is an economic challenge for all companies' accountants.

Options for financing strategies involving owned equity and by debt to maximize net profit per share (EPS indicator, earning per share) are supported by finding the critical point / the equilibrium point between the two strategies considered to have constant interest rates, as shown below:

Equilibrium point is at the intersection of straight lines which give the chosen financing strategies S1 or S2, where net earning per share is equal for both options, according to the formula:

$$\text{Eps} = (\text{Gp} - d) (1 - \tau) / N \text{ and}$$

$$\text{Cp} = (\text{N2} \cdot \text{D1} \cdot \text{INTr1} - \text{N1} \cdot \text{D2} \cdot \text{INTr2}) / (\text{N2} - \text{N1}), \text{ where:}$$

$$1,2 = \text{Strategy version;}$$

$$\text{Eps.} = \text{Net earnings per share;}$$

Gp = gross profit;

d = rate ($D \cdot \text{INTr}$ where: D = debt in the form of loans, credits and

INTr = interest rate);

τ = corporate revenue tax rate;

N = number of shares

As a conclusion, the variability of financial profitability depends on the economic risk expressed by the variability of economic profitability and leverage as an expression of financial risk.

When undertaking a justified high-risk activity, shareholders want a higher return on equity. Their attitude is boosted by the fact that as loans rise, profits are higher too, and the entity is more profitable with a return under the influence of increasing financial leverage ratio.

By promoting an optimal ratio between owned equity and credit, it is possible to use credit as a way to increase performance. The condition required to obtain a higher return on equity is that, through proper management of assets, to achieve a higher efficiency than the cost of borrowed sources, otherwise the emergence and the consequences of the financial risk will be imminent.

As it concerns credit risk analysis, experience, training and actions of managers to achieve and improve business functions are *sine qua non* in business lending. Moreover, the relations is a key factor between banks and customers, it can determine the quality of these relationships and their sustainability. Only by improving its quality, it can act as a shock absorber for various impacts but also to promote a sustainable economic development (2).

The impact of higher risks on revenues can be expressed as follows:

Revenue obtained from:	Risk categories			
	Interest rate risk	Credit risk	Liquidity risk	Equity risk
Interest rate	H	h	H	
Asset use (AU)		H	H	
Return of assets (ROA)	H	H	H	
Equity multiplier (EM)				H
Return on equity (ROE)	H	H	H	H

H = high probability that a high risk could raise the revenue rate

h= medium probability that a high risk could raise the revenue rate

Diagnosis of Tourist Activity on the Romanian Coast

Trașcă Elisabeta
Moldova State University
elyza_tr@yahoo.com

Abstract

Constanta County coast was an important tourist destination zonal market, promoting coastal tourism products and spa. Romanian tourism offer, has changed little over time (especially the southern coastal resorts), becoming uncompetitive in relation to the demands of tourism demand and related tourism products on international markets. The spas on the coast, requires, in turn, the modernization and refurbishment. Black Sea coast, will be competing offers and other new season: Montenegro, Serbia, Albania, Ukraine. After conducting a SWOT analysis of the Constanta County coast, it was found that the emergency is of great technical progress in the implementation of spa activities and operation of tourism both treatment factors, as well as spa treatment for the recovery of health.

Key words: spa, tourism product, the diagnosis

J.E.L. classification: M20

Romanian Black Sea coast stretches about 240 km, between Ukraine and Bulgaria, the Danube Delta in the north to the coastal city Vama Veche, located on the border with Bulgaria. In terms of capitalization of interest, except for areas of the Danube Delta, the Romanian seaside is arranged and exploited for tourist purposes only for a distance of about 82 km from Cape Midia (the North) and to the border with Bulgaria (South) , An area where there are 18 coastal localities of which 13 are tourist resorts of national interest Navodari, Mamaia, Eforie Nord, Eforie Sud, Techirghiol, Costinesti, Neptun - Olimp, Jupiter, Cap Aurora, Venus, Saturn, Mangalia, 2 Mai and Vama Veche. Most coastal tourist resorts in Romania have been developed, 4-5 decades ago to meet two important segments of the tourism market: segment passive type sunlust, whereby the

demand for sun and beach and spa tourism segment (balneotherapy).

Currently, both types of products offered on the European market are outdated and are in the Romanian seaside declin. Romanian seaside resorts faced in recent years, with a reduction in visitor traffic, the tourist offer fails to live up to expectations only partly tourists. Spas on the coast requires, in turn, shares of upgrading and refurbishment. On the Romanian coast, there are over 150,000 beds in hotels, villas and agro resort, representing 40% of accommodation capacity in Romania. Season itself takes about 3 months. Although, quantitatively, things are good, is not enough room for quality. Romanian seaside needs as many events as well as new investments.

In an analysis of the tourism season at the end of 2008 season consisted of: internal summer destination was the Romanian seaside. A measure to increase the number of tourists has been increasing tourist traffic to the end of the season: May, June and September. The hotels have started opening early, but unfortunately, many businesses (restaurants, terraces, shops, discos) have kept the gates closed until June. This while the first series of foreign tourists (Germans, French and Scandinavian) began to arrive around May 10 for the program "Coast for all" was underway. The trend of the season has been widening since 2007.

Black Sea coast will be competing by other coasts offers. It's about the Ukrainian Black Sea coast. Montenegro also start to steal from customers who could be the target of Romania, and also Albania, which promises that it will develop as a tourist destination litoral. A regional comparison shows that Bulgaria competitors, receiving almost four times as many tourists in accommodation establishments than Romania, also won an annual average increase of 11%. Ukraine and Turkey - as smaller competitors such as Serbia and

Montenegro - far exceed the growth rate of the Romanian tourism.

Increased tourism in Croatia - although more modest 8% per year - six times more attracted to foreign tourists in accommodation establishments compared to Romania.

There is an interesting variation of the structures of visiting the seaside resorts, and the mountain, with a greater duration of stay recorded in the Black Sea than in the seaside resorts that an average of over 7 nights from just over 2 nights, suggesting that foreigners are visiting this coast as part of their destination, while many visits to ski resorts are part of the circuit along with other locations. In 2009, the agency promotes the predominant category of accommodation packages with four, three and two stars, while the previous years promoted predominantly offers 4 and 5 stars. It also records a drop in business travel, conferences and congresses.

SWOT Analysis coast

Constanta County coast was an important tourist destination zonal market, promoting coastal tourism products and spa. Romanian tourism offer has changed little over time (especially the southern coastal resorts), becoming uncompetitive in relation to the demands of tourism demand and related tourism products on international markets. Tourist reception structures and especially leisure offer are outdated, uncompetitive (South Eforie, Saturn and Venus), tourism services and tourism programs are made stereotype and modest quality and value for money is inconclusive. After conducting a SWOT analysis Constanta county coast, were found the following:

Strengths

- natural environment conducive to development of tourism activities (Black Sea, fine and sunny beaches, sandy sea bottom and no rocks, low slope, no tides);
- accommodation capacity high, in full extension (about 1 / 3 of the total accommodation capacity nationwide, a place in the country);
- special tradition in tourist activities (over 100 years); Dobrogea-area practice has a

significant potential for many types of tourism (archaeological, historical, ecological, oenological, ethnographic, religious, etc..) strengths of the ecotourism opportunity.

- potential high health spa;
- special interest of local public authorities and the local tourism sector development;
- Mamaia is rated resorts of national interest;
- the emergence of new tourism products, new to this region (Aqua Magic Telegondola, water fountains, small squares where there are different manifestations of modern art, casinos and amusement parks);
- geographical position favorable to the development of new tourism products (itinerary tourism, cruise tourism, business, etc..)
- historical and cultural heritage value;

Weaknesses

- Techirghiol lake water quality degradation, depletion of lake mud Nuntasi
- anthropogenic pollution of the Black Sea water.
- overcrowding Mamaia, Eforie Nord, Costinesti, 2Mai, Vama Veche during the peak summer season and on weekends;
- insufficient parking places, in relation to the number of tourists during the summer;
- lack of permanent tourist products;
- some practical undertakings high prices that discourage foreign tourists, they have the possibility to choose the best tourist destinations in terms of quality / price ratio (Bulgarian coast);
- lack of adequate infrastructure development of cruise tourism (tourism and leisure ports);
- weak in terms of historical and cultural tourism potential of the area;
- the presence of the commercial and industrial sites in the vicinity of tourist areas creates some problems of image and comfort and is an important factor of environmental pollution;
- lack the legal and financial environment and stable tax incentive, which will attract domestic and foreign investments in the area.
- local authorities and have had no legislation to enable them to develop and promote tourism season, these "authorities" remain solely the task of central authorities
- blocking projects for marinas and artificial

islands, coastal construction of roads, facilities for open sea navigation in the Danube Delta to central government authority.

-lack of interest of governments in promoting foreign investment in air traffic and airport development Constanta, which has contributed greatly to the fall of the Romanian seaside image.

Opportunities

- the position at the confluence of three major geopolitical zones, sets the stage for higher recovery of the tourism potential available in the Constanta area and its proximity;
-vicinity of Delta, Macin mountains, monasteries in northern Dobrogea, the region's agricultural potential and valences of the folk villages, represents an important support for tourism development in general and in particular tourism itinerary;
- river Danube and the Danube - Black Sea tourist arteries may represent new spatial perspective of tourist ports in coastal recreation, contributing to the development of cruise tourism;
- economic development of coastal tourism generates a beneficial business.
-national-level decisions, regional / local on the reconstruction of lake Techirghiol solutions to the phenomenon of narrowing of beaches and water pollution in the Black Sea.

Threats

- competition exerted on regional tourism and local businesses a low capacity to adapt to a unique and competitive market;
-decrease in interest for Romanian tourists indigenous tourism products;
-erosion of beaches and cliffs can affect long-term development of tourist activities in this area;
-vicinity of industrial sites and commercial port is an important risk factor contributing to environmental degradation and generates continuous air pollution and water pollution, diminishing the area's tourism potential;
-allocating public funds for tourism development, on political grounds;
- lack of coherent development policies and strategies integrated coastal zone (infrastructure and engineering services, protection and rehabilitation of the natural

and built, etc..) discourage some foreign investors wishing to invest in tourism in this area.

- poverty, still has people in the area.

Conclusions

This analysis seeks to identify in what situation is currently tourism and to highlight weaknesses that need to be addressed and opportunities to be exploited. In the seaside resorts are necessary actions for modernization of equipment supported accommodation, catering, to the treatment, but also to diversify the recreational facilities that are still insufficient. For better organization and planning of resorts are recommended:
1.the systematization and definition of functional areas (bathing area), corroborating the data on the optimal exploitation of natural healing factors, the most favorable locations, measures to materialize the sanitary protection perimeters (Techirghiol, Eforie Nord);
2. sizing and other spa building volume and capacity factors and natural healing qualities (Techirghiol)
3. arrangement of spaces and their use for therapeutic purposes;
4. Judicious and economic use of natural healing factors by management, storage and transport rationally to avoid deterioration and loss (mud from the guests);
5. use of complex machinery and high-tech spa. Priority in terms of material development strategy specific health tourism, I would suggest setting up in all resorts with spa prevention programs, the base material for their application:
- outdoor trails for running and walking practice;
- the design of surface water in warm weather beaches for practicing procedures with contrasting thermal factors (heliotherapy with cold baths);
- furnished rooms for practicing gymnastics programs and group of sports such as: badminton, tennis, volleyball, etc.;;
-the design of dried or wet bath hyperthermia (sauna type);
- expanding sectors of massage therapy.

6. diversification in some climate stations with a single type of therapeutic substance use by natural factors:

- bringing the station, or preparation of sludge (eg Eforie Nord):

- heliotherapy-practicing and cold baths when the season permits;

7. The development of physical therapy, insufficiently equipped resorts quantitatively and qualitatively, by completing and upgrading training facilities allow for the practice of increasing exercise capacity and strength of muscles and accessories necessary for the practice of physical therapy recovery .

To emphasize the specific character of natural healing factors and / or experience in some centers are medical teams will study the possibilities of creating specialized units for prevention, treatment and recovery of patients belonging to certain groups of diseases (ex. rheumatism, lung affections , allergies, neurological disorders, etc.).

In perspective, it requires careful examination and research gaps and inconsistencies, while products among potential mineral spas and built areas (eg Techirghiol, Eforie Nord, Saturn, etc.). The implementation of technical progress in the spa business is a real emergency; special efforts are needed to upgrade facilities and medical devices in the treatment area. Given the scale of health tourism in our country, it is necessary to involve the wider Romanian industry in solving this problem, complex national interest, related to the material, it requires a scientific structure to a unitary concept, premise deployment quality of tourism activities and greater efficiency.

The Modernization and the Development of Romanian Tourism Present and Future

Trasca Elisabeta
Moldova State University
elyza_tr@yahoo.com

Abstract

Romania's integration into the EU has contributed positively to the development of tourism in the country because there are European money funds that will be directed to infrastructure, accommodations, food, recreation, treatment units and last but not least the promotion.

Romania can become a competitive player on the European market for business tourism, which marks important increasing and in this time, but must move from promoting tourism to implement an appropriate marketing policy by creating events and participation in international touristic fairs. Romania will receive up to 2013, the European funds of 150 million Euros for tourism promotion and information programs, the Regional Operational Programme. O.M.T. anticipates that in 2020 to an estimated 1.6 billion arrivals in international tourism.

Key – words: the consumer, the tourism development, recreation

J.E.L. Classification: M20

EU's regional policy is a policy whose stated goal is to remove the economic and social disparities between different regions of Europe, acting on significant areas for development, growth and SME sector, transport, agriculture, urban development, environmental protection, employment and vocational training, education, etc.. Conceived as a policy of European solidarity, regional policy is mainly based on financial solidarity, i.e. the redistribution of part of the Community budget contribution made by Member States to regions and poorer social groups, about one third of the EU budget is allocated to this segment.

For 2007-2013, EU cohesion policy

has been reformed to better meet the objectives set in Lisbon and Goteborg (competitive economy based on knowledge, research and technological development, sustainable development, employment). Following this reform, the policy will have three instruments: the European Regional Development, Cohesion Fund and European Social Fund.

Cohesion policy in its new form, has three objectives:

1. Convergence: supporting growth and job creation in the least developed countries and regions.

2. Regional Competitiveness and Employment (supporting regions, other than those left behind as development level, to achieve the Lisbon targets)..

3. European Territorial Collaboration (promoting a balanced development of the whole EU area, by encouraging cooperation and exchange of best practices among all EU regions). The last objective will have three axes of action, namely: cross-border cooperation, transnational and inter-regional cooperation.

Romania's integration into the EU has contributed positively to the development of tourism in the country because there are European money funds which will be directed to infrastructure, the restoration of historical and cultural heritage, to train the personnel in the hospitality industry, to improve the quality of accommodation and entertainment.

Thanks to a very tough competitive environment in many European markets, the Romanian tourism will have to adapt quickly to the human resources to create skilled manpower and necessary investments for its retention.

The main brands to be developed in future to represent Romania as a tourist destination both externally and internally as business as

tourism, health, cultural, as well as the adventure.

In the last years business travel is increasing by about 15-20% per year. This increase would have more clout, but lack large conference center that allows the organization of events with thousands of participants, transport infrastructure and lack of heavy promotion in the international profile of this growth is expected to leave.

Romania can become a competitive player on the European market for business tourism, which is registering important growths in this time, but must move from promoting tourism to implement an appropriate marketing policy by creating events and participation in international fairs of tourism. Thus, the priority markets for Romania are Germany, Austria, Italy, France, USA, Germany, Russia, Hungary, Great Britain and Ireland, while the Scandinavian countries, Benelux and the Iberian Peninsula are secondary targets.

Arrivals from Europe increased by 21.0% over the previous year, while the European Union grew at a rate of 20%. In the countries of origin, significant increases were recorded in Bulgaria (48%), Hungary (15%), Italy (14%), Germany (15%), United Kingdom (13%). There were important increases in arrivals from the Republic of Moldova (43%), Turkey (9%), while arrivals from Ukraine are at the same level as in the previous year

Source: INS

A decisive role in the marketing policy it has to identify the consumer. Our country would benefit if the consumer – the target would be the young European. Romania offers an appropriate range of outdoor activities both summer and winter, and has a growing program of musical events, sporting and other events in Bucharest and elsewhere in the country and offer relatively low cost. Carpathians and the Danube Delta are the main areas in which to develop ecotourism in the small to medium scale. The growing tourism segment will be

recorded on tourism events, due to accelerated market growth businesses in the country.

World Tourism Organization, together with Romanian specialists has developed the Romanian Tourism Master Plan, a program to identify shortcomings and propose solutions. The document focuses on the exploitation of tourism in areas such as Bucharest, Transylvania, Black Sea, Bucovina, Maramures and Danube Delta. Implementation of the Master Plan is scheduled for the next 20 years.

Objective of the Master Plan is to identify vulnerabilities of the tourism industry of Romania and to draw strategic directions on how it can be restructured and the resources can be provided, and how it can be regenerated in order to compete effectively on the world market

Table 1 Percentage of visitors from the main regions of origin in 2006 and 2026

Region of Origin	2006 %	2026 %
UE	47	56
Rest of Europe	47	34
Rest of the world	6	10

Source: Estimates based on the Master Plan arrivals

Master Plan includes several directions including market research, providing functional institutional structures, a marketing strategy that targets potential markets and professional training of employees.

Objective of the Master Plan is that by 2013 to transform Romania into a quality tourism destination based on its natural and cultural heritage that meets European Union standards regarding the provision of goods and services and achieve sustainable development, in terms of environmental, the tourism sector into a growth rate superior to other destinations in Europe.

The document says that the tourism development program should be directed in the following directions:
- weekend travel, culture, recreation, tourism circuit in Bucharest;
-cultural tourism, nature tourism, ecotourism,

ski and spa tourism in Transylvania
 - the beach, recreation, spa on the Black Sea;
 - cultural tourism, ecotourism, nature, ski in Bukovina;
 - cultural tourism, nature tourism, ecotourism in Maramures;
 - nature, ecotourism and recreational tourism in Danube Delta

The funds which can be made of the strategy for tourism plans are the 150 million revival for the brand in Romania, promoting tourist destinations, as well as funds to 700 million Euros for projects by the National Authority for Tourism.

Table 2 Estimates of domestic and international visitor expenditure

Year	Costs International visitors (mil Euro)	Costs Internal visitors	Total costs visitors
2005	877	1.878	2.755
2011	1.726	2.385	4.561
2016	2.947	4.058	7.005
2021	4.798	5.914	10.712
2026	7.740	8.329	16.069

Source: Estimates based on the Master Plan arrivals

Master Plan identifies five key areas which should receive attention. It is about research, institutional structures, training of employees in industry, tourism planning and marketing investments.

National strategy that will result will be established and priorities in general are known to specialists and are the cultural tours, business travel, the Danube Delta, cities like Sibiu and Brasov, spa tourism and agro-tourism.

Romania's tourist brand, the program that will be invested 20-30 million Euros, began in April 2008.

World Tourism Organization has criticized the current slogan of the Romanian tourism, because it does not communicate the essence of Romania for potential visitors. They were surprised by the fact that their expectations about the country have been greatly exceeded. The challenge faced by Romanian tourism is to show the whole world before they get into the country, how many beautiful

things and experiences can offer. Romania will receive up to 2013, the European funds of 150 million Euros for tourism promotion and information programs, the Regional Operational Program.

Climate change increases the hopes that tourism operators will be able extend the summer season, so it is expected that 160 million Euros will be obtained annually from the proceeds of the season. An approximate amount will be obtained and the spas in conditions where there is clear indication that shows that they have gained ground in the last year. According to NBR data, from January to May 2009, foreigners spent 308 million Euros in Romania, with two million Euros more than the same period last year, but 176 million less than the money left by tourists in Romanian abroad.

Adjacent to the accommodation services, namely the organization of conferences or entertainment, contribute to increased revenue from tourism. Basically, these services generate no less than 25% of total revenues from tourism. Increasingly, many hotels are turning to so-called segment, arranged the facilities for organizing seminars, conferences and business meetings. As a conference destination, the most requested areas are Bucharest, the Prahova Valley, and more recently, and the coastline. About three quarters of segment revenues are generated by the Bucharest conference, and hoteliers want to take advantage of rising demand for such events. It became obvious that hotels that have conference facilities to manage properly developed to insure a higher occupancy rate and grossed more consistent. According to tourism officials, the capital contribution this year will be less than 180 million Euros, one of the 'engines' main business is tourism, which predicts a 87% contribution. According to calculations NATA in Bucharest, the business tourism receipts contributing 60%, while the share is 15% Cluj, Timisoara - 10%, Constanta - 7%, Brasov - Iasi 5% - 3%.

Taking into account the actions taken by the countries competing in foreign markets, countries with annual budgets greater than the promotion of Romania (Bulgaria - 10 million, Poland - 11 million, Hungary - 28 million, Turkey - 76 million), it requires amplification of pan-European advertising and national television channels, installation

of street billboards (out-door type), the exposure of the Romanian tourism offer transportation.

Channels may be present for promoting our message with the video broadcast advertising "Romania - always surprising, " 30 seconds, which is the national mark of Romanian tourism are:

- Pan-European television channels like Euronews, Eurosport;
- national channels from countries considered in this critical period to promote Romanian tourism to Germany, Scandinavia, Czech Republic, Russia, Slovakia, Hungary, Poland.

The promotion of Romanian tourism product in the offer coast, are under consideration that are of interest for Romania, countries like Germany, Austria, Netherlands, Spain, Czech Republic.

Efficient management of Romanian tourism

Creating a competitive interest offerings on domestic and foreign tourism product development involves the following directions:

- Modernization and development of the national tourist product, so that Romania should be distinguished from other countries as tourist destinations;
- modernization and development of the national tourist product, so that Romania should be distinguished from other countries as tourist destinations;
- diversifying the tourism product specialization and deepening of religious and promote higher quality development offering new deals as market trends;
- creation of centers / areas / tourist areas and areas selected model, with financial support from central government and local investment as well as international capital markets;
- optimization to maximize the business and cultural component of the product to attract profitable customer structure changes;
- improve the quality of tourist facilities and development of tourist capacity in areas where tourism demand is greater than supply obligations;
- setting priorities in the overall infrastructure proposals to overcome existing difficulties for tourism;

- raising the standard of basic and complementary tourist services according to category of comfort and pricing;
- approval of the bid;
- stimulating the development of forms of tourism and tourism products complementary / parallel need to ensure a response to certain segments of domestic demand (tourism, youth, rural tourism, social tourism, health tourism, business travel, safari);

Development of tourism in the context of sustainability, even in all the objectives, programs and development actions:

- * environmental protection and improvement in tourist areas;

- * programs and plans to expand the built environment to comply with environmental legislation, relating to urban and regional planning and the tourism, which has the effect of harmonizing and improving the environment;

Tourism in 2020

World tourism in 2020 will be characterized by the use of equipment, more advanced technological equipment and extending computing, automating many travel services, exploitation of new tourist destinations, now considered less accessible, increasing desire for knowledge, adventure and travel .

O.M.T. anticipates that in 2020 to an estimated 1.6 billion in international tourism arrivals, these tourists will spend more than 1500 billion dollars.

Projections show that in 2020, Europe will continue to be the largest tourist area receivers, but it is anticipated that this position will be seriously threatened. If in 2006 the share of Europe in terms of arrivals is 57.7%, projections for 2020 indicate a rate of 45.9%.

Tourism is not only a school about others, but considering how we live with others, how will we behave. Our world, one created by the producers of tourism, is a global one ethnic group: the human race. Any mistake can lead to incurable trauma. And this on a mass of people called "tourists".

Cultural Values and Entrepreneurial Culture in the Romanian Space

Trofin Maria Irina

„Anghel Saligny” Technical College of Bacău, România
dromereschi_irina@yahoo.com

Abstract

Cultural dimensions play an important predictive role in generating specific combinations of organizational behavior, hence the special stake of knowing and their recovery. The process of formation and change of values is an adaptive process that does a few important factors which may cause differences in value systems at both individual and cultural level. Cultural values affect the supply of entrepreneurs, and the culture itself has its own rhythms of evolution. Entrepreneurship is an engine of economic and social development. Study the complex relationship between entrepreneurship and economic growth, measuring the level of entrepreneurial activity in international comparison is justified by identifying factors influence the level of entrepreneurial activity and policies that can boost the level of entrepreneurial activity.

Key words: cultural values, changing values, entrepreneurial culture.

J.E.L. classification: L26, M14.

1. Introduction

Beyond the partisan interpretations of economic policy, globalization must be seen as a mode of manifestation in the context of real market information asymmetries, increasing returns (when technological progress is hard), the effects of agglomeration (clusters), multiple equilibria in different cultural worlds. Perception must become the "opening"[1] under the impulse of mutual societies and technological change advanced search of economic progress without "flattening" of cultural values. Social cleavages fragile democratic political process and reveals the asymmetry between economic and political globalization, the

latter meaning and functioning of multilateral institutions [2]. The increase is necessary to assume its social responsibility by both public institutions and private organizations in the business or nonprofit. Enhances cultural values and become fertile ground for the manifestation of entrepreneurial culture, called to give specific solutions to regional and global issues.

Conceptualizing culture involves a subjective set of resources that includes what was functional and was sent to inter-generational experience. As the individual values are sources of motivation for individual action on a cultural level, they define the rules and goals that trigger and drive the behaviors of individuals in that culture [3]. Cultural values like "freedom", "welfare", "security", "fairness" implicit or explicit abstract ideas are shared by individuals belonging to the culture about what is right, good or desirable for society[4]. They are sent to members of a society by daily exposure to customs, laws, rules and organizational practices ([5], [6], [7], [8]). For this reason, adaptation to social reality and informal socialization are most important in transmitting cultural values than formal socialization. The principle is that of communicating vessels: sharing experiences, integrates and are integrated to various degrees in the social values of their communities.

In formulating intercultural differences have an important role language, perception of time and space [9]. Cultural values are externalized to the societal institutions such as family, education, economic institutions, political or religious systems by their goals and their modes of operation. The special attention in the investigations undertaken have enjoyed work-related values. This not only explains that gainful activity is the main source of income but also by the social status it offers. As Max Weber put in relation with the spirit of the Protestant ethic of capitalism,

studies have pursued the connection between work-related values (considered integrated general values of life) and overall economic performance as a desirable goal([10], [11], [12], [13]).

2. The change of values under the influence of socio-political changes brought into the Romanian

With the establishment of communism in Eastern Europe, socio-economic situation began to change in a way that was not anticipated. The new living conditions were introduced by the new political regime entailed a new way of relating to social reality embedded. Attitudes and behaviors valued once or were not prosecuted or were encouraged by the new socio-political. Schwartz, Bardi and Bianchi [14] have identified two mechanisms that have affected the fundamental values of the countries of Eastern Europe: a direct ideological indoctrination and the process of human adaptation to new living conditions created by the totalitarian system. The adaptation process is achieved by acclimation (people increase the importance of those values that are easily reached, being strengthened) and clearing (inhibited lessen the values that are being rejected). For example, restricting individual freedom has resulted in a diminution of the importance that people attach to the initiative or risk taking, personal achievements, creativity, and especially social responsibility.

Therefore, the formation and change of values is an adaptive process that does a few important factors which may cause differences in value systems at both individual and cultural level. Thus, religious differences or economic level the country can be so affected. Although communism had different organizational structures from one country to another impacts communist ideology was different. Roman Catholic countries of Central and Eastern Europe (Czech Republic, Slovakia, Hungary, Poland and Slovenia) were more easily adapted to a market economy but have shown more resistance to the communist ideology while Orthodox-majority countries (Bulgaria, Russia Serbia and Romania) had a prolonged transition to a market economy and yet

rhythmic breaks in updating the democratic and political values. However scores correlate values and average income per capita (in countries in eastern and western Europe) showed a low level of economic importance in the formation of values [15].

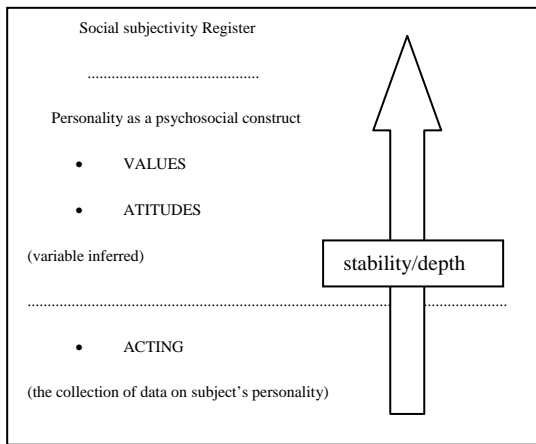

Some clarifications are needed to accompany the permanent judgments on cultural values: a) divalent material (functionary/structuraly) and spiritual (transcendent) value, b) social desirability, c) and axiological foundations of moral value (because of changes macro and trend of globalization, there is no consensus on what is "right" and what is "bad" [16]). Relative to realities of Romanian society we are older or that the concept of *locus of control* (LOC) [17] on the subject tend to think that maybe controllers facing events in life (internality) or the inclination to believe that this control is exercised by other external forces, independent personality (an externality). Inverted population pyramid linking Romania's population disruptive economic policies of recent years and accumulating a significant number of negative life experiences (unemployment, accidents, repeated failures) confirmed the relationship between LOC and the status of independent variable "age" reported by Rodin [18]. According to him, people tend to adopt a predominantly foreign, thus causing the control exercised faith in others rather than themselves.

After '2005 few relevant research on value profiles made in the Romanian context (Gavreliuc [19], Schwartz [20]) reveal important aspects of the Romanian mentality, that entity meets all ideas, conceptions of reality, attitudes, values and modes of behavior of individuals. The Romanians proved to be the most pessimistic about the future, bringing arguments that political chaos and fewer jobs. This approach is commendable by permanent confrontation with the forgotten past policy promoted at all levels of society post-revolutionary obsessive and not necessarily from the spirit of conservation.

The study of social values based on Schwartz model developed in three phases (between 2002 and 2010) revealed values and intergenerational transfers in post-communist Romania. The historic event "rupture" Revolution of 1989 was aiming at its impact

on social attitudes and values shared fundamental. Dimensions were assessed independence-interdependence, self esteem, instead of control, self-determination and the SVS value matrix. Research assumes that values are a consistent predictor of structure and behavior [21] . Hence the importance of studying social values, especially in the deep records (attitudes, values) which encodes the most significant interpersonal strategies to open default.

Figure 1. Value-attitude-behavior relationship

Source: Boehnke, 2008

The research was started in 2002-2003 and conducted on three age groups: "Generation 50" (socialized overwhelming communism), "Generation 35" (secondary socialized to internalize an experience of Communism, Revolution have acquired present positions of the decision nodes of social networks) and "Generation 20" (not part of 1989 Previous office in the world, which holds a fragile neutrality visiting a selective memory, but have begun to insert social strategies in a society profoundly changed against the communist).

Figure 2. Portraits of intergenerational value

Controlling Value Categories	G50	G35	G20
Conservative (status quo, group solidarity, traditional policing)	4,06*	4,68*	4,21
Hierarchy (emphasizing the legitimacy of hierarchical allocation of roles and social resources)	2,12*	2,97	2,29

Harmony (emphasizing the harmonious integration of the individual life in its environment)	4,19	4,17	4,08
Egalitarianism (encourage community engagement at the expense of the individual to promote the welfare of others)	4,62*	4,23	4,46
Intellectual Autonomy (promoting ideas and individual rights in order to achieve objectives)	4,78**	4,12	4,43
Emotional Autonomy (promoting individual independence in the acquisition of a positive emotional experiences)	3,56	3,21*	3,81
Seizure (subject to quality has increased and control natural and social environment)	3,96	3,77	3,82

The scores recorded, the generation that is less predictable G35- instability, ambivalence and vulnerability. It integrates a number of social-historical traumas [22], that encodes the identity profile (most pronounced conservatism, favoring the most intense hierarchy, egalitarianism, intellectual and emotional autonomy most modest).

In the long term, characteristics such as interdependence, self esteem high, externalism, low self-consciousness, seen as diminished choice, low self express pronounced disengagement of youth from the less young. How are structured fundamental values and attitudes show they are equally "old" as their parents, vulnerable, dependent and less willing to take their lives.

Without incriminating "generation of sacrifice" adaptive strategies have to reinvent a historical context, political, economic and social again, the Romanians remain open to positive change, analogous to the communist era dissidents as an engaging side of a trans configuration value (enhanced by Christian dogma) in dealing with global entropic social and political context.

3. Determinations cultural impact on economic development

The most relevant cultural dimensions impact on economic development proved to be individualism and collectivism. Individualistic societies it promotes the "homo economicus" (need for autonomy and independence, connections with other valued modestly) while collectivist societies, the "homo sociologicus" (reciprocity, loyalty, harmony and the need for social support). The challenge of economic development in a globalized world calls for reconciliation of cultural values.

Sensing complementarity, R. Ball [23], assumed a bilateral relationship: the nature of individualist / collectivist a society affect economic development and growth and induce changes in its structure individualism or collectivism.

In itself, the manifestation of individualism or collectivism is not good or bad but counter-productive or phases of the economic cycle. Here we can talk about the lag between economic cycles and culture, fostered by the perception of time and ripped the "burning" stages. For example, the emergence and development of capitalism is linked to the prevalence of "homo rationalis" and individual interests. In such societies, social rule became "invisible hand" guided by principles of economic exchange scale favors liberalizing economic development in its growth phase. In phases of consolidation, economic development is facilitated by collectivism. Reciprocity, trust and morality underlying the collective interests and are internalized, justifying any purpose other than personal. This explains the efficient functioning of economic enterprises in collectivist societies. On the other hand, corporate social rules, indispensable in a world of borders, is the expression of collectivism, because obedience to their individual interests unilaterally waived. Excess of collectivism (bureaucracy, corruption and preferential treatment) is harmful to economic development.

Might conclude that promotes economic development and inhibits individualism collectivism. Inglehart [24] and Inglehart and Norris [25] argue that people in rich countries decreases concern for material wealth "at any price" and increases the so-

called post-material values (non-materials). Beyond the classification guidance and tools you need to rethink the extent to which the alleged collectivist values such as: social justice, altruism and self-sacrifice, or the alleged individualistic such as freedom of expression and enhances economic development option. This assumption starts from the premise that trade and the market does not always determine the rules and pro-social behaviors, social dilemmas as an example [26].

4. Entrepreneurial culture in the Romanian space

Yale Richmond in his 1995 paper, From Da to Yes: Understanding East Europeans, said that Romania is "the culture confusing and unstable in Eastern Europe." Geography and history Latinism determines the diversity and particularities of the Romanian cultural orthodoxy. Being positioned at the crossroads of multiple national cultural influences, the Romanian culture in itself is difficult to describe.

However, S. Văduva[27] attempt an assessment of Romanian culture in terms of the framework provided by Hofstede.

Individualism / collectivism. From the communist era Romania was forced to thinking collectivism, Romanian culture today is moving towards individualism. There are several arguments in favor of individualism development in Romania: a reorientation towards Western culture, particularly noticeable trend among the new Romanian entrepreneurs to comply with the Western model both personally and professionally, the emergence of private property, which motivates and calls for courage and initiative economic, but more recently emerging orientation towards profit increased accumulation of wealth, power and high social position.

Power Distance. Distance to power in the social, economic and cultural Romanian has been and will likely remain high, because the Romanian society is still structured like a pyramid based on education, family environment and income. Pyramid Peak continues to be the dream of all Romanians. Second is almost nonexistent middle class. Her absence caused more power increasing distance between social classes. Most wealth

seems to be divided between members of a small percentage of the population. Thirdly, the majority of Romanian institutions is still characterized by a complex hierarchical structure and a large number of hierarchical levels.

Masculinity / Femininity. Romania has been and remains a country whose culture is oriented towards manhood. In Romanian culture, men have jobs and take important decisions with power and authority to a greater extent than women. Romania is the country of a patriarchal society where women, considered above all as mothers and wives, are less important positions outside the home. Typically, men in authority in the family and feel more strongly the responsibility of earning income.

Although the great diversity and complexity, however, one can identify two distinct types of organizational culture in Romania: bureaucratic culture and entrepreneurial culture, supporting the hypothesis that these two categories are the extremes of a continuum with a wide variety of expression. Bureaucratic culture is typical of state-owned companies, companies undergoing privatization, the former state companies during privatization, autonomous companies, educational institutions and state sponsored health, public institutions, military institutions. This can be characterized as still strong inertia, targeted to the inside system and highly involved in political life.

Entrepreneurial culture, ongoing training is typical for private companies set up after 1989. This is where the two forms of red tape bureaucracy and red tape mechanical training. Specific mechanical bureaucracy is a highly developed hierarchy, which dominates the regulations. It defines strict management of subordinates. Professional bureaucracy, much decision-making power is distributed to professionals and analysts. The structure is quite decentralized, but the high degree of bureaucratic standardization in methods of operation. Qualifications predetermine behavior more standardized categories of highly skilled experts, appointed professionals. They are specialists in the gathering, processing and use of data, are secretaries, economists, financial experts, lawyers, etc.

5. Analysis of the integration of entrepreneurial culture in Romanian organizations

Existence, the discovery of entrepreneurial opportunities and the decision to exploit them are considered to be the starting point of entrepreneurial activity [28]. Considering the above, I accepted definition of international research program Global Entrepreneurship Monitor (GEM) on the entrepreneur and the entrepreneurial phases. Database Global Entrepreneurship Monitor (GEM) survey contains adult population of Romania from 2007-2009. GEM reports demonstrate the link between a country's economic development level and rate of early-stage entrepreneurial activity ([29], [30], [31]). GEM results in 2009 confirm that institutional and demographic characteristics, entrepreneurial culture and economic wellbeing of a country emerging entrepreneurial characteristics [32].

Accepting the recommendations of Arenius and Minnie [33], the study focuses on population characteristics, such as demographic structure, individual skills and attitudes on entrepreneurship, taking into account the classification of these socio-demographic factors and perceptual factors. Several factors influence individuals' decision to start a business, such opportunities in their environment perception, knowledge and skills, knowledge of other persons involved in entrepreneurial activity, fear of failure. The factors studied are grouped into demographic variables (for example, age, gender, household income, education level and occupation) and perceptual variables (for example, fear of failure, finding opportunities, self-confidence).

In Romania, early-stage entrepreneurial activity rate in 2009 is 5.02%, higher than that measured in 2008 (3.98%). These rates are among the lowest in the economies based on efficiency.

Figure 3. Rates of entrepreneurial activity in Romania (%)

Rates of entrepreneurial activity	2007	2008	2009
Entrepreneurs in training	2,90	2,54	2,79
Owners of new firms	1,30	1,56	2,30
Established business owners	2,50	2,07	3,38

Early-stage entrepreneurs	4,02	3,98	5,02
---------------------------	------	------	------

Source: GEM adult population survey, Romania, 2007, 2008, 2009.

Individual perceptions of entrepreneurship describe changes in the analyzed period. During the global financial and economic crisis percentage of those who feel that fear of failure would prevent them starting a business has increased (from 28.3% in 2007 to 50.4% in 2009), while the rate of those who feel that in the next six months will be good opportunities for starting a business environment in which they live has declined (from 26.2% in 2007 to 13.8% in 2009).

In 2009, early-stage entrepreneurial activity rate was 5.02%, a rate higher than that measured in 2008 (3.98%). Even though the rate has increased, it remains one of the lowest among economies based on efficiency. The variables that significantly affect their desire to start a business are: household income, knowing other entrepreneurs, age, sex, fear of failure, confidence in knowledge and entrepreneurial skills, promoting the perception of entrepreneurial success in the media and occupation. In 2007-2008 the factors of influence or change, age, sex, fear of failure and factors of influence became occupation probability of becoming an entrepreneur at an early stage during the global financial and economic crisis.

6. Conclusions

Interaction between culture and economics related to material prosperity of the country concerned and the specific social and political institutions. If formal institutions are ineffective, social capital and trust to replace them to maintain social cohesion. Some components of individualism / collectivism facilitate economic development, others not, and the shortcomings are more noticeable when formal institutions are less developed / evolved. Currently in Romania, it crystallizes the culture of entrepreneurship especially in the private equity firm, founded after the creation of free market mechanisms in Romania. Institutional and demographic characteristics, entrepreneurial culture and

economic wellbeing of a country emerging entrepreneurial characteristics.

The Investment Development Path – Literature Review

Trufin Ovidiu Serafim

“Alexandru Ioan Cuza” University of Iasi

ovidiu_trufin@yahoo.com

Abstract

This article aims to identify the differences between the Narula's model regarding the five stages of investment development path and the economic reality. In other words, we try to determine if the model presented by Narula reflects what is happening on the economic environment of a country or not. Is the Narula's model of five stages of investment development path really capable of reflecting the level of development of a country or not?

In order to answer to these questions 10 relevant articles had been analyzed. These were published during 1996 – 2009 in the Transnational Corporations, Journal of International Business Studies and Working Papers Series.

We find out that even if the Narula's model of five stages of investment development path is very detailed and concret model the reality show us that some countries may be in different stages than the one specified by the Narula's traditional model.

Key words: foreign direct investment, investment development path, Multinational Corporation, host economy

J.E.L. classifications: F23, F43, O11

1. Introduction

The notions of country development and foreign direct investment (FDI) have always been at the forefront of international business research in the context of globalization [8]. The main reason for this situation is given by the fact that the economic development of a country depends on the net outward position which is the difference between inward and outward FDI.

On the other hand, the attention was usually focused on the multinational corporations (MNC) that responded to the

globalization phenomenon by adapting their strategies, way of organizing their activity and the modalities in which they interact with the host economic actors. This context influenced the opportunities and challenges that the governments that were following FDI – assisted development strategies had to face.

As a result to all this, the effects that the foreign direct investment of the MNC have it on the host economy represented a major subject of debate in the area of international business research [10]. It had already been demonstrated that the dynamic relationship between foreign direct investment and the level of development of a host country is reflected by the investment development path (IDP), the newest concept regarding FDI [5].

The concept of IDP was used for the first time, in 1981, by Dunning. In 1996, Dunning and Narula redefined the concept and in 2001, they extended it to incorporate trade.

Since then it had become the base of a wide range of theoretical and empirical studies which are analyzing the situation that exist in Austria, Spain, Portugal, Finland, Ireland, Central and Eastern European Countries, Korea and Taiwan.

2. Methodology

This article aims to identify the contradictions that exist between the Narula's model and new discoveries regarding the five stages of IDP.

In order to achieve this goal a content analysis of 10 relevant articles have been made. The analysis was focus on identifying a definition of the concept of IDP, determining the most important stages of the IDP and the way in which these stages may be identifying in the economic reality.

The selected articles were published during 1996 – 2009 in the *Transnational Corporations, Journal of International Business Studies* and *Working Papers Series*.

The results of this analysis will be showed in part three and four of this article. So, the third part will focus on the model developed by Narula in order to surprise the five stages of IDP while the fourth part concentrates on differences between Narula's model and aspects identified in the economic reality.

3. The Narula model of five stages of IDP

According to the concept's basic proposition, the inward and outward investment positions of a country are tied to the country's economic development. Changes in the volume and structure of FDI lead to different values in the country's net outward investment (NOI) position, defined as the difference between the gross outward direct investment stock and the gross inward direct investment stock. The changing NOI position passes through five stages intrinsically related to the country's economic development [5].

So, a country experiences five stages of economic development characterized as having different pattern of inward and outward investment. Outward FDI is expected to take place in later stages when a country has accumulated a certain amount of ownership advantages among firms.

According to the IDP theory, countries evolve through five stages of development (Figure 1) [4].

Figure 1: The Pattern of the Investment Development Path

Source: Dunning and Narula, 1998

Stage 1 is associated with preindustrialization. Inward and outward FDI flows are almost nonexistent because domestic markets are very small,

infrastructure is inadequate, the labor force is poorly educated and commercial and legal frameworks are undeveloped.

The development of some location specific advantages (for example, basic infrastructure, eventually as the result of government policies) will give rise to *stage 2*. This leads to more inward direct investment, mostly targeting the emerging domestic market in consumer goods and infrastructure, but too little outward investment, because domestic firms lack ownership advantages. Consequently, the net stocks of outward investment will become increasingly negative. In this stage, inward FDI stocks rise faster than GDP.

Stage 3 is associated with less spectacular growth rates of inward FDI. This is eventually overtaken by outward direct investment, and the net FDI stock will for the first time start to increase despite remaining negative for some time. Behind this change are the domestic firms' growing ownership advantages, which become also more firm-specific and less country-specific. Stronger domestic firms will be more competitive in the domestic market, while engaging in resources seeking investment in less developed countries and in market and strategic asset-seeking investment in more-developed countries.

The deepening of these trends will eventually turn countries into net outward investors (*stage 4*). Location advantages become almost entirely based on created assets, and the firms' ownership advantages that result from managing and coordinating geographically dispersed assets become far more important than those based on the host country's specific characteristics. Intra-industry production is a consequence of the growing similarity in the advantages of countries at this stage, and it generally follows prior growth in intra-industry trade. It results from an increasing propensity by TNC to internalize trade and production.

Finally, Dunning, Dunning and Narula postulate the existence of a *stage 5* in the IDP, corresponding to today's situation in the leading developed countries. With permanently high stocks of both inward and outward FDI, the net outward investment (NOI) position of stage 5, countries will revolve around zero, alternating between positive and negative balances, depending on

the short-term evolution of exchange rates and economic cycles.

4. Differences between Narula's model and the economic reality

Research on the IDP concept as applied to different countries encompasses many additional factors. Focusing on the case of the United Kingdom, Clegg (1996) frames his analysis in the context of country competitiveness. He draws attention to technological factors that influence competitiveness besides FDI and government policy, and extends the investigation of the U.K.'s IDP to bilateral components according to region and country as well as to the sectoral destination of FDI.

Graham (1996) explores the U.S. IDP using data beginning with 1950 and questions the original model's assumption that, in the fifth and final stage, the NOI position tends to fluctuate around the 0 level. Ozawa's (1996) analysis of the Japanese experience stresses the effects of restrictions placed on inward FDI and introduces the technology development path as a surrogate for the IDP concept [7].

The IDP in the Spanish economy is of special interest to the present study because the development trajectories of Spain and Poland resemble each other, albeit separated by a considerable time gap (eighteen years if access to the European Union is considered as the base). Campa and Guillen (1996) extensively present the Spanish case, concluding that Spain has difficulty moving out of Stage 2 of the IDP model, not because of a deficiency in ownership or internalization advantages of Spanish firms, but because of the continuing attractiveness of location advantages in the Spanish market.

Lall (1996) offers a synthetic evaluation of the IDP concept, as evidenced in developed as well as developing and newly industrialized countries. He maintains that structural changes in ownership and location factors influence trends in international capital flows, corporate behavior, and government policy. According to one of his suggestions, the IDP could be better measured by the international transfer of intangible assets instead of relying only on FDI. His main observation is that countries

exhibit long-term deviations from the IDP model, caused mainly by the nature and efficacy of government policy. This might necessitate extending and modifying the model to encompass all of the identified subpatterns. As for the role of government policy in the said model, Lall identifies three main types: a passive approach to FDI and technology upgrading; a proactive approach to attract and guide FDI to activities that most benefit local development and a selective approach to FDI, using it to acquire foreign-created assets and at the same time, developing the potential and especially the technological base for local firms [9].

Buckley and Castro (1998) look at the IDP of Portugal, pointing out some key weaknesses of the IDP concept. They question the IDP's predictive capacity, given the unpredictable character of economic and non-economic factors. Among the non-economic factors, they cite political events such as Portugal's entry into the European Free Trade Association (EFTA) and the European Economic Community (EEC), the 1974 revolution, and the transformation in Central and Eastern Europe [4].

Bellak (2001) analyzes the Austrian IDP, stressing the usefulness of distinguishing an IDP approach for small countries and focusing on bilateral and sectoral analysis similar to that of Clegg (1996). Bellak (2001) argues that, on the basis of collected empirical evidence and taking the level of development as the main criterion, Austria may be classified as being in Stage 4 or 5 of its IDP. If, however, its constantly deteriorating NOI position is considered, the country falls into the category of Stage 2.

Austria's inconsistency with the ideal IDP model may be explained by its extensive use of exporting as an alternative to outward FDI: Austrian firms' weak technological base led to their low capacity to generate firm-specific advantages and inward FDI increased after Austria entered the European Union in 1995. Much of the outward Austrian FDI is undertaken by foreign subsidiaries of MNCs resident in Austria, and therefore, any ownership advantages should be de facto attributable to the parent company from the relevant home country [4].

Barry et al. (2003) find support for the IDP model in their study of Ireland. The IDP concept is also positively verified in a

bilateral U.S-Irish framework, because the United States is the largest source of incoming FDI, as well as the principal destination of outward FDI from Ireland. Outward FDI is mainly oriented toward nontraded products, such as construction materials, paper, and packaging, and the ownership advantages of Irish MNCs tend to be based on management and experience [1].

A complex evaluation of the IDP concept and its shortcomings, and suggestions for modifying it, are found in Durán and Ubeda (2001). Calling for a new approach to the IDP, they draw attention to such methodological problems as the incompleteness of the concept of NOI position as an indicator for analyzing the effects of structural changes on inward and outward FDI, and the insufficiency of gross domestic product (GDP) per capita to indicate a country's level of economic development [9].

The first dilemma appears in countries in which hardly any inward and outward FDI is made and which are classified as being in Stage 1 of the IDP. Their NOI position will be close to zero, similar to developed countries in Stage 5 of their IDPs. To solve this paradox, Durán and Ubeda (2001) propose to look at inward and outward FDI in absolute and relative terms. Suggestions to deal with the second issue revolve around including structural variables that reflect not only the degree of economic development, but also each country's peculiarities and the nature of its international trade.

Another of Durán and Ubeda's (2001) significant contributions to the debate around the IDP concept concerns their redefinition of the fourth stage. Their amended version includes developed countries that have a structural gap due to fewer endowments of created assets; the same levels of inward FDI but lower levels of outward FDI compared to countries in Stage 5; and a positive or negative NOI position, but in all cases, lower than that of countries in Stage 5. All of the proposed modifications depend on the availability of additional or more detailed data and offer much wider analytical possibilities [6].

A growing amount of research on IDP relates to the transition economies of Central and Eastern Europe. Kubiela (1996) invokes the early version of the IDP in his analysis of

the role of technology transfer and FDI in restructuring the Polish economy during the first five years of transformation to a market-based system. The first stage of the IDP is driven by basic production factors, which are abundant and relatively inexpensive. The next two stages fall into the investment-driven category, in which inward FDI is focused on standardized products and then on export-oriented mass production of medium-technology products that generate economies of scale. Finally, there is the innovation-driven (fourth) stage, in which technology is not only imported, appropriated, and improved, but also generated domestically. Inward FDI is now of the strategic asset-seeking type.

A comprehensive and insightful analysis of outward and inward investment in selected Central and East European countries is conducted in a study edited by Svetlicic and Rojec (2003). One of its principal recurring themes states that the IDP concept is useful to understand and explain the outward internationalization process of transition economies. Within the same study, Rosati and Wilinski (2003) investigate how the IDP concept fits with FDI in Poland. They find that the limited extent of outward FDI from Poland is due to factors such as a large and growing domestic market, low savings rate, and a still-low degree of openness in the economy. The outward FDI is mostly market seeking, focused on the markets of Europe [7].

Boudier-Bensebaa (2004) undertakes a synthetic and comparative approach, applying the IDP concept to the entire region of Central and Eastern Europe, including Russia and the former republics of the Soviet Union, and to the fifteen members of the European Union. The Eastern countries concerned are classified into four distinct groups according to their per-capita level of GDP and NOI position. The NOI position of the Eastern countries places them in Stage 1 or 2 of the IDP, while the NOI position of the EU countries suggests Stage 4 or 5. The first and most advanced group of the Eastern countries consists of Czech Republic, Estonia, Slovenia, Hungary, Slovakia, Poland, Latvia, Lithuania, and Croatia. The group is identified as moving toward the end of Stage 2 of their IDP, or even toward the beginning of Stage 3. The NOI positions of

the Eastern country groups and subgroups reveal a tendency to converge. But as far as income levels are concerned, no convergence is found either inside the Eastern countries or between them and the European Union. Finally, the author posits that data on FDI stocks and GDP do not cover all of the factors affecting FDI and development. In the FDI sphere, nonequity forms of investment are left out. As for the effect on FDI, besides GDP, elements such as EU accession, globalization, and the transformation process per se should also be taken into account [3].

5. Conclusions

The IDP is an attempt to provide a framework for a series of concatenated dynamic processes associated with development and MNCs. But the stages of the IDP should be taken as indicative rather than categorical. The IDP framework needs to be used and interpreted in the broad sense, as it is first and foremost a tool which analyzes the interaction between FDI and economic development. The broad version of the IDP focuses on the heterogeneity of both FDI and territories; to interactions and turning points and to the role of policy orientations.

We have provide some suggestiones for a future research agenda to better understand the developmental implications of FDI in Romania. Our analysis of the case serve to illustrate how important is to place the IDP framework whithin the context of the countries institutions and policies. Is is essential to stress that overdependence on FDI to drive industrial upgrading has its risks.

In recent years, the global economic crisis has had a very negative effect on MNC's operations, questioning the formerly prevalent optimistic view of the seccess of FDI - assisted development.

Changes in the policy options available and the continuous restructuring of MNCs imply a growing pressure to develop the kind of sustainable competitive location advantages that enable upgrading throughout the IDP.

Agriculture - a Chance for the Economy in Crisis of Romania

Abstract

Agriculture is not a problem; it should be seen as a solution, alongside with other domains, for taking Romania out of recession. In order to achieve this goal, the attention should be shifted towards the increasing of efficiency and competitiveness in this regard, a strong infusion of foreign direct investment being necessary. The ecological agriculture may be a way to support the revival of the Romanian agriculture, and even a part of Romania's economic recovery.

The role of the Romanian agriculture is the following: development based on knowledge and innovation, conservation, biodiversity and maintenance of the rural heritage, promoting an economy with a high rate of employment, in order to ensure social and territorial cohesion.

Agriculture and the rural development must become ecological, fair, efficient and effective.

The Romanian ecological agriculture is a response to the revival of the agricultural life, if there will be found competitive and efficient solutions to the four characteristics of the agro systems: productivity, stability, fairness and development.

Key words: sustainable eco-agriculture; the smart growth of the agriculture, social inclusion, transparency in food processing, agricultural price volatility.

J.E.L. classification: Q13, Q17, Q57, Q58

The emergence of agriculture is considered the first great economic revolution in human history. By inventing the agriculture, the man went to the creation of the food he needed, greatly increasing the

efficiency of his effort and reducing the hazard [1].

Between the years 2008-2009, the Romanian agriculture had to face the global financial crisis and also to be a domain which had to support the Romanian economy. The Romanian agriculture between 2008-2009 is characterized by the following coordinates: GDP (Gross Domestic Product) per capita - 47% of the one of the European Union in 2008, the agriculture in GDP - 6.4% (1.8% in EU-2007), employed population in agriculture - 29.8% of total employed population (5.6% in the European Union - 2007); in the year 2009, 19% (2.1million) of the 11.2 million “full time” jobs in EU agriculture were in Romania (2.2 million people in Poland and 1.2 million in Italy), the rural population accounts for 45% of the population, 14.7 million ha of agricultural land, 9.8 million ha have been supported by Community Fund Policy - (2,000 commercial farms apply intensive agriculture - 5.1 million ha of farms developed extensive subsistence agriculture - 3 million ha; in Romania the average holding is of 3.3 hectares, 64% of farms produce for their own consumption; net importer of food products); 1.532 million Euros deficit in 2009 (of which 1.301 million Euros represent Intra-community trade and 231 million Euros represent extra trades.) [2].

In 2010, the Romanian agriculture model is as follows: the agro-industrial agriculture, consisting of hundreds, even thousands of hectares, is adapted to the market and relative advanced from the technical point of view; the middle agriculture is underdeveloped compared to the European model of agriculture which is represented by the middle family farms; the subsistence agriculture consists of many micro farms which are not on the market but for the own

consumption; the farmers are mostly elderly people who own the majority of the lands; an important part of the agricultural economy is carried out on lands owned by individuals.

The contribution of agriculture, forestry, fisheries in the calculation of the gross domestic product is of about 6% of GDP, and of about 1.7% of GDP in the Member States of the European Union [7].

Table 1
The percentage of the agriculture, forestry and fisheries in the GDP

Agriculture is not a problem; it should be seen as a solution, alongside with other domains, for taking Romania out of recession. Under these conditions, although 7.5 billion Euros have been allocated in Romania, for the years 2007-2013, by means of the Common Agricultural Policy, only fewer than 10% of these funds have been absorbed. If those 3.5 billion Euros would not have been spent on imports but directly on agriculture and if there would have been a government program of support, in five years Romania would have become the third agricultural power in Europe, after France and Germany. Massive investment is needed to defeat the meteo-dependence. Few from the great investors come to invest in agriculture. The land price has increased 5 times - but it still holds itself 3-7 times lower than the European average - so a solution would be to accelerate access to EU funds. The absorption of EU funds increased in 2010 more than twice from the year 2009, but not enough [6]. To this lack of European investment there are added the infusion and the low levels of foreign direct investment, especially in tangibles and intangibles. The foreign direct investment is of a low value of 286 million Euros, representing only 0.6% of the total FDI in Romania [5]. This situation reflects the "transience" of the Romanian agriculture and the need to grant a special consideration, in order to support this vital industry for the recovery of the Romanian

economy, in terms of competitive and economic, social, environmental efficiency on the EU and world market.

Romania is on the 6th place in Europe as an agricultural area used (after France, Spain, Germany, Britain and Poland) and on the 5th as arable land (after France, Spain, Germany and Poland). The distribution of the land fund according to its use shows that the arable land is about 64% of the farmland and one third of the total area, 4.8 million ha, is occupied by pastures and meadows, orchards and vineyards and it is about 3% [7].

The evolution of the agricultural production (the prices of the producers, plus the subsidies on products and less the taxes on products) reflects a reduced crop production, meaning a production from 61, 9% in 2006 to 59.6% in 2009, in the benefit of the production resulting from livestock, which has experienced a significant increase of 8.5% compared to 2008, but only 0.7% compared to 2007 [3].

The evolution of the field crops shows significant increases compared with 2007, despite a reduction in the values recorded in 2009 with 21% overall grain crop. In terms

of sunflower (266% in 2010 compared to 2007), rape (255%), soybeans (106%), the production recorded an ascending trend in 2010 compared to 2007. It is worth noting that steps are to be seen in practicing an intensive agriculture for this kind of crops because of the slight declines of the cultivated land while conditions for the growth of the production are recorded. The position and the role of the field crops in agriculture would be even greater if the efficiency and productivity should be mandatory in their management.

Romania, as a vineyard country, occupies the 5th place for its vineyard area and the 6th place for its grapes and wine production in the European Union.

The area planted with vines occupies 1.5% of all farmland in the country. The three major vineyard areas of Romania are the Carpathian area, the Carpathian hills area and the Danube area. Within these areas there are eight wine growing regions and a total of 38 vineyards were over 100 varieties of grapes are planted. The four wine complexes which are dominant on the market are: Murfatlar (29.9%), Jidvei (19%), Cotnari (13.8%) and Vrancea Vincon (7.9%). In 2009, the grape production has exceeded the average recorded between 2007-2008, and the fruit production increased by 143.000 tonnes compared to 2008 [3].

Table 4

In the vine-wine field, the focus is on the Support Programme, which runs the Community funds with an annual financial allocation of 42.1 million Euros between 2009-2013 for the following measures: the restructuring and conversion of vineyards, the vineyard harvest insurance, the use of the concentrated must in order to raise the alcoholic strength of the wines, the wine promotion on the markets of the other countries.

A goal of the Romanian agriculture is represented by the finding of the balance between the fields of plants and animals. It aims to increase and improve the livestock

breeds for meat and milk. It also aims to increase the areas occupied by the protein forage for the improvement of the livestock production aimed, in turn, to encourage the development of agro-processing units.

Livestock is an important part of the Romanian agriculture and is one of the main activities in the rural sector (see table 5).

Between 2007-2009 there were awarded grants to improve the quality of genetic material used for the first calving heifers, gilts, produced calves, sheep, ewes and rams, silkworms depending on the production of merchandise sold and also on the development of certain criteria of breeding and breeding productive performance.

Table 5

Despite the measures taken, the results are to be long expected because, except for the sheep and goats where there have been recorded increases in livestock, in all the other livestock sectors there have been registered decreases. The milk production is in decline, and the one of eggs and wool has recorded a slight increase. There are farms holding a very small area in point of the number of milk cows. Fragmentation means reduced bargaining power. Concerning the small farms, you can not achieve high costs comparable with the ones of the great producers. This sector holds the record for the number of farms in Europe, but not in terms of efficiency. On the milk market, only 22% of the produced milk in farms go to trial and finally in stores, the rest being used either for the own consumption or for "at the gate" marketing [8].

The ecological agriculture experienced a dynamic evolution. At the beginning of the financial crisis in Romania, the total area under cultivation was of 240,000 hectares, an area that grew by 68% compared to the one in the year 2006. For the year 2010, the ecological production area increased 1.82 times compared to 2006, meaning an increase of 8% compared to the year 2009. This development is based on the growth of the

arable area and of the one related with the collection of the spontaneous flora [4].

Table 6

Period / Indicator	2006	2007	2008	2008/2007	2008/2006
Cultivated areas, based on the ecological production method (ha)	143.194	190.129	221.411	1,16	1,55
Certified ecological areas (ha)	78.083	143.179	152.881	1,07	1,96
Areas during the conversion (ha)	65.111	46.949	68.530	1,46	1,05
The share of the agricultural areas by the model of the ecological production, total agricultural area of Romania (%)	1,00	1,40	1,60	0,20	0,60

Source: Ministry of Agriculture and Rural Development, Ecological Agriculture in Romania. Present and prospects of development, Ecological Agriculture Conference, Arad Chamber of Commerce and Industry, 25 November 2009

At the beginning of the financial crisis in Romania (2008) the characteristics of the market for the ecological products show the following: an emerging domestic market estimated to 20 million Euros, with a steady growth; the distribution channels are represented by wholesale shops, sales at the gate of the farms by means of specialized stores, on-line sales or seasonal markets; the consumption is targeted to customers aged between 30-50 years and with an above-average income; the most requested items are milk, cheese, vegetables and fruit, eggs, cereals, bread, honey and products for children [4].

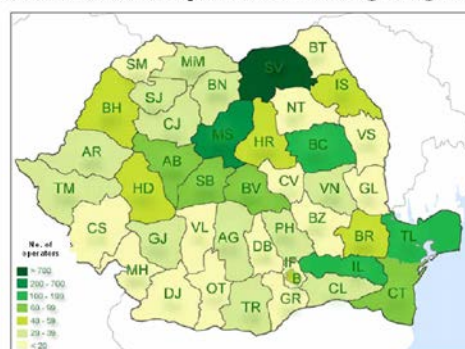

In the year 2009, on the domestic market there were sold fresh vegetables and fruits, herbal teas, bread, pasta, pastries and confectionery, flour and cereal flakes, sunflower and soybean oils, wine made from ecological grapes, honey and bee products, eggs and processed products: cow and sheep milk (swaitzer, cheese, butter, and cream cheese), rice, soy, hemp seed (spreads, tofu, pate, and hemp oil); pork, beef and snails (sausages, bacon, and pate), fruit and vegetables (juices, jams).

It means that, of the total number of the registered processors in 2009, 18% of manufacturers deal with fresh fruits and vegetables segment, 16% with milling, bakery and confectionery, 17% with honey products, 10% with milk products, 6% with other products, 2% with wine, oil and margarine and 1% with heliculture (see figure 2) [3].

Figure 2

The distribution of the operators in the ecological agriculture

Source: www.madr.ro, Ministry of Agriculture and Rural Development, Agriculture of Romania in figures, November 2010

There were used 136,600 tonnes of ecological products worthing 103 million Euros, for the intra-community trade in the year 2009, up 20% compared to the year 2007.

The main products on the Community market were oil and protein, grain, berries and mushrooms, processed milk, honey and derived products, sunflower oil. Romanian products were marketed in Germany, Italy, Greece, Switzerland, Holland and France. In the future of the ecological agriculture, Romania should take into consideration the new perspectives of the European Union. By "The Common Agricultural Policy up to 2020 - How to respond to the future challenges in nutrition, natural resources and territories", in mid 2011, the European Commission will present formal legislative proposals and it will also propose: a new vision of direct payments, which must integrate the "green" component, a distribution in a fairer and a more transparent way, the intensifying of efforts towards combating the climate changes and the innovation in the rural development programs; the transparency of the food chain in order to provide the Member States new tools to combat the excessive volatility of the commodity prices in agriculture [8].

The future implementation and the accomplishment of the objectives of the development strategy in ecological

agriculture should be in line with the new approaches of the European Union. Thus, the quality objective of placing the ecological agriculture in the center of the Romanian agriculture as an engine of sustainable development should be linked to quantitative targets - the increasing of the cultivated areas (by the year 2013 to 5.08% of the agricultural area), the diversifying of the range of ecological products, the expansion of the internal market for ecological food products, the increasing of the "per capita" consumption [4].

The Romanian agriculture is a sector that fails to provide Romania the needed currency resources. The increase of the value of exports has not yet been able to offset the deficit created by imports, although their value was reduced by 476.3 million Euros, amid the economic crisis. There is an upward trend of exports. In the year 2008, compared to 2007, the export value has doubled, and in 2009 compared to 2008, the exports grew by 61 million. The trade deficit recorded in 2009 was of 1.5324 billion Euros, down by 537.3 million Euros, compared to 2008, and of 622 million Euros compared to 2007. The European Union is the main partner in Romania's agricultural trade; in 2009, shipments of agricultural products to this destination had a share value of 77% and the acquisitions of the European Union Member States have held a share of 80% [3].

To strengthen the role of the Romanian agriculture in the revival of the Romanian economy, there should be considered the following priorities: smart growth - the developing of an economy based on knowledge and innovation (research and technological development combined with efficient use of existing resources lead to increased productivity), sustainable growth - the promoting of a more efficient economy in terms of the use of some greener and more competitive resources leads, on the one hand, to providing "public goods" for the society (such as conservation, biodiversity and maintaining the rural heritage) which, on the other hand, might lead to creating new jobs by means of the expansion of agriculture and local markets supply; social inclusive growth - the promoting of an economy with a high rate of employment, to ensure social and territorial cohesion (about 13.6 million people are directly engaged in agriculture,

forestry and fishing, and another 5 million in agro-food sector, this meaning 8.6% of the total employment in the EU and 4% of EU GDP [2].

Agriculture and the rural development must become ecological, fair, efficient and effective and also must have the following objectives: reliable food production - to ensure safe and sufficient food supplies, according to the permanent rising demand, the global economic crisis and the larger volatility of the market, in order to contribute to the food security; sustainable management of natural resources and climate policies (farmers have to be more aware of the environmental issues than the economic ones although these costs are offset by the market); maintenance of the territorial balance and the diversity of the rural areas (agriculture remains a major social and economic engine in the rural areas and an important factor for maintaining of the countryside area).

The market for the ecological agricultural products (bio) is estimated to 40 billion dollars worldwide, representing 2.5% of the overall food and beverage market. Romania could benefit from this trend. The existing and potential agro ecologists could develop a strong ecological agriculture sector, by making use of the arable and forest land and by taking advantages from the low level of the fertilizers and the pesticides used in the Romanian agriculture, which could be transformed from a competitive disadvantage into an advantage.

The Romanian ecological agriculture is a response to the revival of the agricultural life, if there will be found competitive and efficient solutions to the four features of the agro systems: productivity, stability, fairness and development. The agro ecologists of the agro system must best manage the agro system's elements such as soil features and the interactions between plants and insects, and also the use of the social sciences in order to understand the effects of the soil cultivation practice in the rural communities, economic constraints of developing new methods of production or cultural factors indicating soil cultivation practices, and the presence of the "bio" allows striking [8].

In conclusion, agriculture is an important sector in the real economy having an important social role but a modest competitiveness

though. The Romanian agriculture has divergent objectives, interests and even solutions of development and therefore there are need different intervention measures.

mihaela_turof@yahoo.com

Abstract

Altered climate and increased global instability, are problems that can not be ignored at all, they must be located in the master plan of concern to people could prevent general environmental disasters.

Both climate change and global instability can be eliminated primarily by switching to energy production based on hydrocarbons to one based on alternative energy.

The process of altering the Earth's existence can be slowed or even eliminated if they pass the economic processes based on the eco tehnological processes for immediate financial profit, meaning it will move from the present industrialized and computerized society to a society based on sustainable development.

The XXI century will build eco tehnological civilization cross that supports care for the environment, protect existing habitat and regeneration of the destroyed.

*Thus it appeared that a new discipline - **Ecotehnology** - which is a harmonious blend of technology and environmental protection.*

Key words: ecology, ecotehnology, environmentale damage, automobile industry
J.E.L. classification: Q56

1. Introduction

Since his appearance on earth, man has influenced the natural environment in the sense he wanted to ensure their protection, food, heating, so for survival and development.

If at first the impact was negligible because of the small number of individuals gradually adjust to the environment, while the effects were amplified. In ancient times, agriculture has seen a rapid expansion over

large areas, affecting more strongly the ecosystem.

From the eighteenth century industrialization increasingly intervened heavily in the natural environment, damaging natural resources and exploiting it by working through various techniques, through increased traffic and population growth.

Human impact on nature has been accomplished by:

- Radically changing the work geographic landscape through large scale as: ponds, lakes, dams, drainage, etc.
- Operation of strong energy and material resources of soil and subsoil
- Climate change negative transformations in the structure of the vegetal cover in particular by deforestation
- Change the structure of ecosystems beyond their recovery
- The destruction of many species of plants and animals, deterioration, change or destruction of ecosystems that had been adapted
- Changing the composition of the atmosphere, water and soil through spills of various products
- Altering the natural gene pool of living beings downward adjustment capacity, restoration and reproduction [5].

2. The emergence and development of ecology

The term ecology was first introduced by German biologist Ernst Haeckel in 1866, which practically joined two Greek words, namely:

- **Oikos** = house, home
- **Logos** = science, speech

So basically ecology as a science can be considered habitat (living space).

The appearance of this field of science has enabled significant accumulation of knowledge about the nature of the naturalists of great value over time.

Development of ecology but has been slow to start, compared with other scientific developments, due to lack of data on interactions between these organisms and the environment, and the purpose of this science, so the practical applications.

After 1930, the ecology has experienced spectacular growth, due to the abundance of accumulated knowledge and awareness of humanity to the environmental causes of errors [3].

Today ecology is defined as the science that studies the conditions of the existing interactions between living things and living beings on the one hand and between living things and environment, on the other side.

The main problems of ecology are:

- study of matter and energy flow in the biosphere;
- principles of biological productivity;
- dynamics of animal populations;
- natural resources conservation principles and reproduction.

3. Eco tehnology – 3rd millennium since

We can say with certainty that there is no area of our existence which have not appeared and technology words, technical progress, new technologies, pollution and sustainable development, special and different-sounding words at a time for hope each of us.

Technology, a term with different meanings, was born, developed and initially consisted of the production materials (all methods of work and technical resources necessary to develop materials production processes), has gradually expanded the benefits of services (transport, municipal services, repairs, household appliances etc.), then to cover production and spiritual sphere (works of art, sport, tourism, leisure, etc.). Therefore, understanding, perception and proper application of technology and other concepts that are directly related to it - technical progress, upgrading and environmental pollution - is a civic duty not only for specialists but for all the protagonists of the third millennium.

Eco technology, this new science has emerged as a necessity of manifesting prominent trends in human development, especially due to the trends of environmental pollution from uncontrolled desire economic development based solely on profit. [7]

Eco technology is the science of applying all the sciences, in order to achieve the goods of a certain social utility in terms of sustainable development and a minimum pollution.

The scientists studied all the transformations that the substance is subject, cross eco technological processes driving these changes work and how to obtain the necessary products company, in terms of sustainable development and optimum efficiency.

Today, the main way of developing high level of wastage due to specific "consumer society" is the technology and eco technology is called now to find an alternative for preserving the environment and solve the general crisis in which humanity is (the crisis of energy, materials raw material resources, protection, reliable and not least economic) [1].

Eco engine technology is an *eco-economy* development, the end result of it being a cross product obtained from one or more material behind an *eco production process* [7].

Eco technology differs from other sciences through the following:

- is a science because it follows the applicative technique with a practical purpose;
- is dependent on time and space, because any discovery of laws of nature is made useful by a specific technology company, and its use is perfected in time for an eco technology;
- does not solve the problem of making a single product, it solved the problems of obtaining an eco industrial production, diversified series of the same social utility, thus becoming an essential condition of human society development;
- based on the concept of sustainable development - of future generations to conditions of life and development at least as good as our generation, as provided by our generation's obligation to preserve and restore, as appropriate, environmental

conditions conducive an existing optimal [2].

Eco technology differs in that the technology must offer solutions for assuming implementation of sustainable development:

- Limit the amount of materials used in their economy through recycling and circulation
- Possible elimination of waste from industrial processes
- Energy conservation and development of new clean energy
- Replacement of toxic materials and biodegradable materials difficult recycleble
- Preservation of environmental factors
- Biodiversity Conservation
- Reduce operating costs
- Improving working conditions [4].

4. The main beneficiary of the development of environmental technologies - automobile industry

Most of us know the huge effort that make for healthy planet, humans and animals through various ecological approaches to nature. Stranger to these moves is neither the international automotive industry, and rightly so, because hundreds of millions of vehicles worldwide spread on the roads have a huge potential for air pollution, global warming accelerate the process and eventually choking the planet. Naturally, the importance of cars is too high to give up their service, but a transformation of cars more environmentally friendly direction was already taken into account. In recent decades, transit trains, heavy but necessary, from cars run on fossil fuels to those which employ alternative energy resources, clean and renewable.

Turnover is difficult and slow to change because the world fleet is, by definition, a war of attrition, but we can already speak about green cars and even about its history.

In the aftermath of World War II, following the example of Germany, Japan would launch project to develop affordable car man. Year 1958 will mark the launch of small car market by a large number of Japanese automakers, the 480,000 cars sold in Japan in 1960 turns into 5.3 million sold by 1970. From there he remained until just a step in the Land of Rising Sun, the negative

impact on the environment began to be felt, especially the air pollution. Emissions caused a sensible increase of cases of asthma, which culminated in an incident in 1970, when many high school students in Tokyo accused of dizziness and headaches as a result of breathing in car exhaust gases emissions. The event boosted awareness about air pollution both in the capital of Japan, and other major cities "inhabited" cars.

A similar problem already had the time most industrialized countries, among them the U.S.. Thus in 1970, was issued "**Clean Air Act**", under the name "Muskie Act", which stipulated a 90% reduction of hydrocarbons, carbon dioxide and nitrogen oxide exhaust gas component, within 5 - 6 years. Stepping on the same tracks, the Japanese government enacted the 1972 "**Act to prevent pollution**". Criteria related to acceptable rates of contaminant removed cars became more severe after subsequent regulations, leading to a recognized threshold of 0.25 g / km exhaust emissions.

Environmental problem has led industrialists worldwide motorists to be aware of the practical implementation of new standards. Were used as the latest technological breakthroughs, such as thermal reactors, electronic fuel injection pump, new engine design elements and catalytic converters to minimize the quantity of toxic substances emitted by motor vehicles by removing gas.

Following the 1973 oil embargo, gas prices increased, a phenomenon that gave birth to a major interest for electric vehicles.

If we think of car environmental history from its beginning until today, the first reminder is worth even the first model with four-wheel electric vehicle, namely electric carriage, made between 1832 and 1839, the Scotsman Robert Anderson . Also, a small-scale electric car was designed by Professor Strating from Groningen, Holland, and built by his assistant Christopher Becker in 1835. Plant Gaston Frenchman invented its own model with the same principle of operation in 1865 and Camille Faure improved partner storage capacity of the battery used vehicle in 1881. Also, the first purely electric car with fuel was invented in 1902 and named Buick Phaeton, a model that later became, in 1916, hybrid, operating both an electric motor and internal combustion.

All these marks of industry pioneering experimental environmentally "friendly car".

These inventions have appeared in practice due to their ambitions and to do otherwise, to show that it can be a different approach to automotive issues, but he had no intention of starting a fashion sparing nature. If we go on this thread, I would say that green cars were born, because the first car, designed in 1769, worked on the principle of energy produced by steam.

In reality, the draft environmental machines began shy of the 1973 Honda Civic, but it actually started after the United Nations Kyoto Protocol, Japan, in 1997, when an amendment appeared on the international treaty on climate change.

The 40 developed countries and the European Community, which ratified the Protocol, have agreed to reduce their collective emissions of carbon dioxide by at least 5%. This objective would be achieved until the period 2008-2012. By the middle of 2007, and 149 other countries, less developed protocol rallied, even having no emission reduction obligations. In 2006, the Protocol covers more than 55% of global emissions of greenhouse gases. The Kyoto Protocol was replaced by a resolution of the summit on global warming that took place in Copenhagen resolution that calls into question much tougher standards with polluting industries and at the same time, more environmentally friendly.

International automotive market transformation strategy, took place on several fronts, all having the same destination, a means of personal transport, efficient and autonomous, environmentally friendly and affordable at prices similar to those of conventional cars.

Global auto industry has not rested in their attempts to find, enhance and promote environmental alternatives and conventional vehicles already mapped directions for environmentally friendly cars plan were followed closely, and developed streamlined.

He started the development of automobile industry on several tracks:

- pneumatically powered machine uses a piston engine that uses compressed air to zero emissions as an energy source;
- battery electric vehicles derive their power from chemical energy of different types of batteries: lead acid and nickel-

metal lithium-ion, lithium-polimner, zinc-air and others;

- solar car which is achieved using solar photovoltaic panels installed on the vehicle surface;
- using hydrogen cars, hydrogen as the main or even sole source of power. Hydrogen vehicles can be used in combustion processes (hydrogen burned in the engine) or fuel conversion processes (hydrogen is converted into electricity to drive the electric motor);
- hybrid cars that combine an internal combustion engine fueled by gasoline and an electric motor powered by a battery.

Delay and slow progress in eco car industry have a lesser or greater tangent to those who rule the empire of oil. Sea oilmen, those who have enriched conventional cars, have exploded and continues to sabotage the initiative by the actions of different natures green. Renunciation, the globe, for the fossil fuels in cars move would seriously harm the interests of those who have created financial empires in the exploitation and marketing of these fields. [6]

5. Conclusions

Given the serious environmental problems and climate change exacerbated in recent years, if the group really want industrialized nations to reduce pollution at least one of the methods of alternative energy for cars will be adopted for mass production of motor "green" vehicles.

Abstract

The European Union has developed a strategy for inland water transport that will be implemented through programs financed by the Regional Development Fund.

The priority areas will focus on improving: transport connections, energy connections, the environment, socio-economic development and security.

This paper will analyze how this strategy is implemented in Romania, through programs concerning the development of inland transport on the Danube. As road infrastructure is insufficiently developed in our country, traffic congestion is an important problem for transportation of goods. Diversifying the means of transport could offer an alternative to road transport, but it must be viable and safe. A main concern is the cost, and we will explore the possibilities to enhance competitiveness of inland water transport. An important factor in this matter is intermodality and related logistics services.

Key words: development strategy, inland water transport, Danube, intermodality, logistics

J.E.L. classification: R48, L91, O18

1. Introduction

In order to increase competitiveness of the European Community economy, new sources of competitive advantage must be identified. The huge economic potential of inland water transport could be one of them.

The European network of inland waters has a total length of 3500 km. It connects hundreds of cities and industrial regions and plays a major part in transportation of goods throughout the continent. A part of this network is the river corridor formed by Rhin, Main and Danube rivers, which connect The Black Sea and the North Sea.

The Danube region covers parts of 8 EU countries (Germany, Austria, Hungary, Czech Republic, Slovak Republic, Slovenia, Bulgaria and Romania) and 6 non-EU countries (Croatia, Serbia, Bosnia and Herzegovina, Montenegro, Ukraine and Moldova). [2]

The region is facing several challenges:

- environmental threats (water pollution, floods, climate change)
- untapped shipping potential and lack of road and rail transport connections
- insufficient energy connections
- uneven socio-economic development
- uncoordinated education, research and innovation systems
- shortcomings in safety and security

Better coordination and cooperation between the countries and regions is needed to address these challenges.

For the period 2007 - 2013, 100 billion Euro funding have been allocated from the cohesion policy (European Regional Development Fund, Cohesion Fund, and European Social Fund). The main objective is to increase the fluvial traffic for goods by decreasing the negative externalities of water transport, as navigation incidents.

2. The European inland water transport strategy

The opening of the markets is traditionally related to competition. An important factor for increasing the competitiveness of the EU industry is the development of the Trans-European network infrastructure.

The European Transport Policy has the role to improve the funding support for developing the inland water transportation, including the Danube.

By diversifying the means of transportation and intensive using of inland waterways, the aim of reducing traffic congestion may be achieved.

In the EU consensus has been achieved on the need for adopting the principle and practice of cost-based charges. As a consequence research has been oriented towards the estimation of social external costs because these are a fundamental input to the price setting process. Extensive research has been carried out on this topic both at European and national level. [3]

A fundamental issue for developing competitive alternatives to road transport is intermodality, as door-to-door delivery is preferred by most customers.

According to The Freight Transport Report (European Commission for Energy and Transport, 2010) there have been few tangible achievements apart from a few major ports with good rail or canal links. Action is therefore advocated to ensure fuller integration of the modes offering considerable potential transport capacity as links in an efficiently managed transport chain joining up all the individual services. The priorities must be technical harmonization and interoperability between systems, particularly for containers.

3. Enhancing the competitiveness of inland navigation

The recommendations for increasing the competitiveness of the waterborne mode are:

- support an extensive use of ICT-solutions to simplify and improve administrative and logistical processes;
- stimulate the application of IWT based door-to-door supply chains as long as it reaches a good level of commercial

competitiveness;

- support the development of container liner services on inland waterways;
- Implementation of River Information Services (RIS);
- create harmonized regulations for the implementation and use of RIS;
- provide funding for innovative inland waterway development projects;
- use synergy effects between information technology (logistics, telematics) and the upgrading of waterways. [4]

The European Transport Policy is oriented towards the rationalization of intra-European procedures. The streamlined dangerous cargo reporting tool, whose use has resulted in substantial savings for companies and organizations, demonstrates how ICT (Information and Communication Technologies) can significantly help to facilitate the implementation of directives that are, otherwise, very difficult to enforce.

The pricing of logistics supply chains is generally recognized as a key driver of modal choice, but not the only one nor the principal factor. In practice in modal choice selection processes it is necessary to take into account a number of variables. This does not mean that policies to influence modal shift by increasing the price of road transport may not be effective at all, but it must be considered that there are limits to the impact of such measures on modal shift. [5]

The development of the CESAR tool (Coordination Action for the European Strategic Agenda of Research on intermodalism and logistics) is an example of how European collaboration may be organized in order to develop common and harmonized tools. [6]

4. Intermodal transport and logistics services

“Intermodal Transport: The movement of goods in one and the same loading unit or road vehicle, which uses successively two or more modes of transport without handling the goods themselves in changing modes. *By extension, the term **intermodality** has been used to describe a system of transport whereby two or more modes of transport are used to transport the same loading unit or truck in a integrated manner, without loading*

or unloading, in a [door to door] transport chain" [7]

Technical improvements of intermodal transport had concerned the development of pallet and suitable wagons for travelling at high speed, an innovative solution for transferring semi-trailers, and conceptual terminal designs with fully automated loading and unloading systems, as well as a system to trace container within the terminal yard in real time, reducing the intervention of human operators.

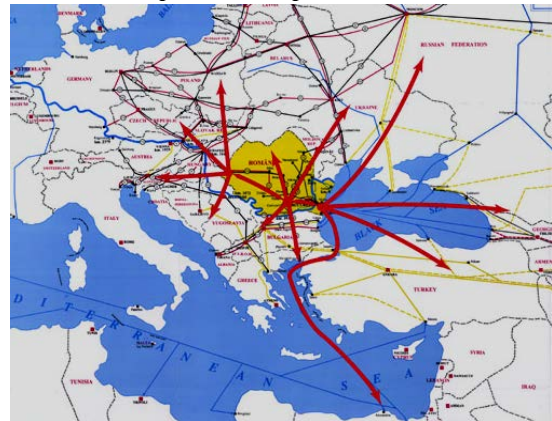

For what concerns the intermodal network efficiency, research has particularly focused on investigating existing technologies and their applications to enhance the efficiency of intermodal and maritime operations and increase their volume by improving and facilitating cargo flows between inland and sea. An innovative waterborne transport concept for inland/short-sea operations was developed, which can replace the currently fragmented and traffic jams sensitive road, rail and waterborne transport. Furthermore, tools for improving the efficiency of door-to-door transport of goods in urban areas were developed, as well as a Freight Transport Monitoring System (FTMS) for intermodal transport chains, which can monitor the status of the delivery and provide real-time information. Research has also provided an overview of the potential and limits concerning the use of semi

5. Case study: The development strategy for the fluvial traffic on the Danube – implementation in Romania

Romania is on the European transport corridors:

- IV (Berlin/Nurenberg-Prague-Budapest-Arad-Bucharest-Constanta-Istanbul-Salonic),
- VII (Danube, the river corridor Sulina and Channel Danube-Black Sea) and
- IX (Helsinki-St.Petersburg-Moscow-Pskov-Kiev-Ljubasevka-Chisinau-Bucharest-Dimitrovgrad-Alexandroupolis).

Figure 1: Position of Romania in The European Transport Network

Source: Arhicom, Foundation European Gateways Platform, 2010

The transportation of goods in Romania benefits from the possibility of choosing between 4 means of transportation: road, air, maritime and fluvial. It is well acknowledged that the road infrastructure in our country is considered to be insufficient developed, especially concerning commercial transportation of goods using large dimensions trucks. As air transportation costs are high and suitable for increased value products, transportation by water is the alternative that has the advantage of low cost.

Table 1: The evolution of modal split of inland transport of goods

Type of transport	2000	2008
Roads	42,9%	70,2%
Railways	49,2%	19,0%
Inland waterways	7,9%	10,8%

Source: Eurostat

The Danube crosses 15 countries and has a total length of 3500 km, still, freight volumes on this river have reached only 10% of its potential capacity [1].

From the total volume of transports, the biggest part is represented by national transports (74.7%) and the transit volume is insignificant.

Figure 2: The inland waterways transport at ports in 2008:

Source: The National Institut of Statistics, Statistic Yearbook 2009

The Directive EC/2005/44 demanded the implementation of River Information Services along the navigable international waterway network. The GIS forum was founded in 1997 by the waterway administrations of Germany, Austria and Slovakia. Since 1999, the group joined the working group of the Danube Commission, followed afterwards by Croatia, Romania and the Ukraine. The GIS Forum aims at more intensive exchanges of geographical data and closer cooperation in terms of the waterway management for the Danube River. In this respect, D4D (Data warehouse for Danube Waterway, Priority Axis 2 – Efficient and sustainable transport systems and access to the information society) was set within the work carried out by the GIS Forum Danube. The D4D project's primary objective was to provide a common and harmonized implementation of European and international standards on the Danube waterway, and recommendations for inland navigation. In particular, it sought to create digital navigation charts for the Danube river in compliance with the European inland ECDIS standard¹⁶ and set up an infrastructure to improve the accuracy of satellite based positioning systems, according to current international standards. In accordance with the regional orientation of the project, D4D also aimed to network national geographic information systems around the Danube and to ensure an efficient exchange of electronic data between responsible waterway authorities. [8]

The network of harbors on the Danube is in the south part of the country and has both fluvial, maritime and fluvial-maritime ports.

As part of the European strategy for development of inland water transport, Romania has developed a program for traffic management, which has been financed through the Authority of Management in Sectoral Operational Programme – Transport (SOPT) by The European fund PHARE 2002/00 – 586.04.09. The project is compatible with the Priority Axis 3 (TEN-T), intervention domain 3.2 “Modernization of fluvial transport and improvement of safety”. The scope of the program is to ensure that European standards regarding safety and real time communication are respected.

The total value of the project is 49.989.094 lei, and eligible value for funding 42.007.642 lei. The non-refundable financing from the EU is of 71.12% (29.875.835 lei) of the eligible value and the difference of 28.88% (12.131.807 lei) must be co-financed by Romanian Government.

The main scope of this project is to create a harmonized inland water transport at European level by interconnecting national RIS centers.

The first stage of the project implemented VTMISS (Vessel Traffic Management Information System), a form of Integrated Maritime Surveillance System that can incorporate various information systems developed for traffic management. It offers real-time information about ships and navigation routes.

As the first stage has been completed, the second stage (named RoRIS II) is in course of implementation since May 2009. The technical aim is to implement a RIS system (Radiology Information System) compatible with EU Directive 2005/44/EC (Directive RIS) on the part of Danube crossing Romania and also interconnecting it to similar systems from Austria, Hungary, Slovakia, Bulgaria and Serbia.

This is the most complex project implemented in Romania as it covers all 23 Romanian fluvial ports (see table 1) and offers an intelligent system of naval transport with the purpose of enhancing the safety and effectiveness of inland waterways of The Danube River. The organizational structure of the system will have three levels, with the following attributions:

Table 2: Organizational structure of RoRIS

Level	Office	Attributions
central	Constanta - Romanian Naval Authority Terminals at Transport Ministry and Interns Ministry	Management of informational flow between all regional and local levels
		Coordination of the system
		Creating interfaces for external communication
regional	Drobeta Turnu Severin, Giurgiu, Galati Tulcea	Centralizing information about fluvial transport on the Danube
local	All fluvial ports on Danube in Romania (see table 1)	Current navigation operations
		Communication with other ports by VHF system
		Collection of initial data from sensors

Source: The Romanian Naval Authority, www.rna.ro

The main objectives of the project are:

- efficient use of ports and terminals
- the reduction of naval incidents, pollution and environmental risks
- efficiency of inland water transport
- maximization of ship capacity and of navigable routes
- the reduction of transport time, costs and administrative work volume
- to ensure an easy connection with other means of transport
- increase of safety

The RIS system offers strategic and tactical information about the fluvial traffic, about the routes, the management of intermodal platforms, statistics and legal regulations.

In order to obtain improvement of safety and efficient management of inland water transport it is necessary to connect the national RIS centers by interchange of:

AIS information

Electronic reports (ERI)

Information about ship identification

The technical project has been developed by ASESOFIT (the company has won the public auction for the implementation of the project) and the results until now are:

- Equipments for the communication, monitoring and IT subsystems have been purchased

- the following software was developed: desktop application type ECDIS for naval traffic management, soft for defection management, application CCTV and security application PKI.

6. Conclusions

For many technical, economic and social reasons, the road is today the dominant transport mode for inland expedition services. However, as a high-capacity mode, inland waterways also have considerable advantages over the road:

- Inland waterway transport has high fixed costs and low variable costs so costs per kilometer and per TEU become lower the higher the transport capacity and the container capacity utilization ratio. Water transport is more energy efficient and has lower costs per tone-kilometer than either road or rail. Up to 500 TEUs at a time can be transported by barge, compared with only 90 by train and only 2 by truck;
- It facilitates the repositioning of large numbers of empty containers at low cost;
- It provides an alternative mode to the road, whose negative externalities are becoming increasingly unacceptable, in response to environmental and societal pressures. [9]

Fluvial transport is not the dominant mode of transport because it has a number of disadvantages. Unlike the road, which possesses a very large interconnected network, inland waterway services can only carry goods to a limited number of destinations which are entirely dependent on the infrastructure. To gain market share, combined waterway-road transport must be more competitive than road transport, both

with regard to the price of door-to-door services and the quality of the service provided (Vellenga et al., 1999). This leads us to the concept of intermodality (which has been presented in the fourth section of this paper) and logistics services offered by port operators and shippers. In order to increase the quality of services that can be provided, we need to have a safe and reliable infrastructure doubled by a communicational system that can output real-time information regarding the position and status of the goods transported. This is exactly what the RoRIS project aims to implement on the part of Danube that crosses Romania. It is important that the project continues and reach all its goals (see the fifth section of the paper).

There are still areas for further research in the field of enhancing competitiveness of inland transport that can be financed, such as intermodal terminals development.

Abstract

It should be understood that we should first of all "join" ourselves by the reconstruction and reshaping of our own system of values and only after that wish to join the united Europe. Is useful to point out that the present day Europe is not that of the Treaty of Rome, but that of the Maastricht Treaty of 1992. There is a big difference between what we understand now in Romania by integration and how it is defined in Western Europe. Thus, in Romania, nowadays by integration we understand rather an attempt to remedy the disintegration. For the western European countries, which had long ago solved their after war problems, integration is defined as a process of "coupling" the economies and institutions, starting with the juridical ones, passing to the educational and finishing with the cultural ones. So the European Community functions as a whole under as many aspects as possible. Integration is thus the expression of a high economic, political, social and institutional consciousness of the integrating countries. Integration is to achieved, and not decided upon.

Key words: integration, economic transition, globalization

J.E.L. classification: P2

The perspective of Romania's integration in the European Union imposed a clear definition and understanding of the concept of "integration" and the term of "transition".

As it was used during the last half of the century, the notion of integration defines phenomena, processes and actions, which take place in the economic, social, political, cultural, philosophical spheres. These spheres are difficult to dissociate. One can discuss and

analyse the "economic integration", the "political", "military", "cultural integration" etc.

The basic principles of the economic integration concern the creation of a shared economic space, the free movement of the production factors, setting up a customs union as well as a shared policy in the economic, monetary, financial and social fields.

The integration of the communist countries in the Comecom was a process imposed from both outside, by the political belonging to an international group and from inside, by the dominant and undemocratic action of a one-party system. Unless other economic alliances, Comecom gravitated round a dominant power and its decisions had a mandatory character. To Romania, history brings many examples of regional bodies, which have mainly promoted national security through defensive alliances, but also the economic security, by concrete elements in the contents of these agreements or through economic projects, which accompanied the regional political initiatives.

Most of the states of the world are now involved in one form or another of international economic co-operation, especially free commercial zones and customs unions, with specific features according to the region where they operate but with the observance of the general conditions. It is more obvious than ever that an economic autarchy cannot function and is doomed to fail with enormous suffering for the population. Perhaps with only one exception – North Korea – the other economic autarchies are not self-imposed, but induced by an international embargo. These situations are characteristic of the states where the national interest is not formulated in a democratic way and is false, perverted interest. It represents, in fact, the interest of a power group, which has and exerts the power in a discretionary way, a group interest imposed by force, a

undemocratic interest promoted to the status of a national interest.

Without claiming to make a detailed presentation of the "economic integration concept", we think it most appropriate to specify that – in relation to a specific geographic area, this is called "regional economic integration". The "total economic integration" supposes the unification of the monetary, fiscal, social policies and requires the setting up of a super-national authority where compulsory decisions are to be taken for all the member states.

The regional economic integration in the conditions of the contemporary globalized world economy consists in the unification of several national economies in coherent economic structures. Of all the regional structures, the European Union is the main economic model of the world of the future from both the perspective of the size of the agreed economic activity and the willingness to adhere expressed by more and more developed European countries. After the collapse of the European totalitarianism the new European democracies expressed their desire to join the European Union.

It should be understood that we should first of all "join" ourselves by the reconstruction and reshaping of our own system of values and only after that wish to join the united Europe. It is useful to point out that the present day Europe is not that of the Treaty of Rome, but that of the Maastricht Treaty of 1992. There is a big difference between what we understand now in Romania by integration and how it is defined in Western Europe. Thus, in Romania, nowadays by integration we understand rather an attempt to remedy the disintegration. In other words, this concept is very close to that of the economic and politician W. Ropke concerning the after war European integration. For the western European countries, which had long ago solved their after war problems, integration is defined as a process of "coupling" the economies and institutions, starting with the juridical ones, passing to the educational and finishing with the cultural ones. So the European Community functions as a whole under as many aspects as possible. Integration is thus the expression of a high economic, political, social and institutional consciousness of the integrating countries. Integration is to be achieved, and not decided upon! After the end of the "cold war" not only

did the European Union not witness the disintegration phenomenon, but due to the Maastricht Treaty it heads to an increased degree of integration.

In the context of the European integration process the term "transition" should be given a new significance. The notion of "transition to the market economy", even if of Marxist origin, includes the deep movements of systemic transformation occurred after 1989 in the Central and East-European space. It defines all the mutations occurred in the totalitarian and discretionary regimes, in the economic and social and political life, towards systems based on freedom, democracy, market economy and the values of the modern civilisation.

The transition period designates a particular phase in the evolution of a society. As our previous experience shows "the transition" from a political, economic and social system, whose viability had become impossible is a long lasting, difficult and unequal process, both in its own dynamics and in the countries where it is enforced. These difficulties are generated on one hand by the global and complex character of the transformations, and on the other hand by the peculiarities and specificity of each society, as well as by the lack of a coherent theory to be applied in the matter.

At present, when globalisation is the major trend of the beginning of the 21st century, we are witnessing, in fact, two great global transitions, which are simultaneous world transitions, namely:

- for the countries in the former soviet space, this is the "new transition to the market economy" – called like that because the countries in Central and eastern Europe, among which Romania have already had a transition to the market economy in the 18th – 19th centuries. This first transition divided Europe in two: the Western Europe, which built up modern industrial structures and Eastern Europe, which opted for a kind of merchandise economy with big gaps of productivity, which now proves to be impossible to recuperate.
- the transition to the intensive cultural informational economy, which is characteristic of the developed countries. This is a transition toward a knowledge-based society.

We can certainly say that the East-European countries, Romania included, are in the "new transition to the market economy" but no one can say where we shall reach at the end of these unprecedented transformations. It is not known, whether these countries will succeed in aligning themselves to the developed countries. These countries are know in the middle of another simultaneous transition, one which is wider and focused on another kind of economy, based on a high cultural and informational economy and to another kind of society, the informational society.

Immediately after 1989 in our country the changes occurred mainly in the political area, so that the pluralist dictatorship replaced rapidly the communist dictatorship. Already than the priority of the political, democratic transformations, the pluralist democracy, which absorbed most of the energies, generated different opinions on the most appropriate solutions for the Romanian economic realities in transition.

Looking back at the Romanian economy in 1989 we see with its huge problems, but in no way at the "0 level". This was an economy, which could have been successfully guided to a new path, integrating it into the world economy. Moreover, the total lack of external debts and the existence of an available amount of almost 2 billion offered the possibility to start introducing new technologies in economy and raising the real living standard of the population provided there was the necessary willingness and responsibility to do so. A coherent reform programme was needed, to carry out in an orderly and efficient way the changes in the system. But in the case of our country, as well as in other European countries, the start was not where it should have been and the beginning of this process had a decisive importance to its subsequent evolution. This was what made several western economists to state the possibility of the "wild capitalism" coming back to these transition countries, as it existed approximately two centuries ago.

The risk of the return to a wild capitalism is fed by several circumstances: the lack of protection of the population against the oppression by the new owners, the very low level of the labour productivity, which makes it impossible to build very soon a more civilised market economy. As no foundation was laid so far to an economic growth, which could occur "tomorrow", the economic situation will

continue to worsen and the conflict between the two poles of society is a proof that we are in the phase of a modern form of wild capitalism. It might happen that this model is the main particularity of the transition economy. The population will also have an important say as far as the transition duration, character and results are concerned. After so many years since its beginning, the population is deeply disappointed by the results reached.

In order to integrate the European structures, Romania makes at present big efforts to solve the serious problems the economy is confronted with. Romania should have permanently in view that the process of making decision in view to join the European Union is supposed to consider, on one hand, the specific Community interests and, on the other hand, the adaptability of the country to the dynamic requirements of the European Union, a system undergoing a permanent transformation.

The two transitions Romania has to perform concomitantly in the present historical stage, the post-socialist transition and the transition from the status of an associate country to that of a Union member state should be carried out in full coherence with the national interests.

In this period of profound structural changes in the Romanian economy and society, knowing the advantages and difficulties of joining the European Union, as well as the membership of other countries, sooner or later integrated, is a priority requirement both in economic and socio-political field. Ant this is so because in integration the human being and his dignity and freedom are at stake. They are expressed on wide democratic, integrated, economically reliable a socially just spaces.

Implementation of International Standards on Auditing in the EU- Objective Necessity

Țugui Valentina

"Valahia" University of Târgoviște

valentina.tugui@yahoo.com

Abstract

The purpose of this article is to highlight the need to implement the Inter-Audit standards in Europe along with their international adoption. Thus we start from the necessity of adopting these tools at European level normalization as their main purposes strengthening the accounting profession and professional standards aimed at stimulating the basis of the auditors. We believe that conducting an audit in accordance with International Auditing Standards involves compliance by auditors to audit all relevant standards, understanding their correct and full text of the application. ISA adoption should be considered as one of the priority measures to restore confidence in the underlying economic recovery.

Then continue and show that although there are assumptions that the introduction of international auditing standards will bring great benefits to the European audit market there are still impediments to their convergence.

Key words: implementation, convergence, financial statements, users, financial audit

J.E.L. classification: G01, M42, P41

1. Introduction

International standardization are the main instruments of international audit standards - ISA and international declarations on audits, insurance, review related. They provide uniform international audit practices, applying the audit of financial statements and the provision of related services. They contain the principles, basic procedures, explanations, additional indications, which are exclusively applicable to all significant issues and how to apply them, except when a

paragraph of which mentions a standard limiting the scope of the standard. If national audit standards conflict with international auditing standards, professional organizations in this country should endeavor to assimilate international standards-obligation assumed by member states by signing the instrument of incorporation IFAC.

As prepared at present, international auditing standards presume the existence of implicit legal requirements, institutional and political ("preconditions") that, in many countries, often are developed or absent. The structure of national economies and the role of external financial reporting of high quality "preconditions" the extent to which these existing efforts to promote implementation of international standards should be regarded as specific issues. Mechanisms for public oversight of the audit function, including the establishment of auditing, quality assurance and control are almost entirely absent in some countries. Models recently introduced in more developed jurisdictions may not always be applicable in situations where the relative importance of different stakeholder groups is different, and national regulatory bodies do not always have easy access to best practices and the emerging international consensus time. There are inherent limitations to the extent that they can make based on international networks of audit firms and individual members at the national level to compensate for weaknesses in the regulatory regimes.

Given the governance arrangements and management of networks and that networks themselves are not regulated (only their member companies are regulated at national level), the main determinant for power quality audit is relevant domestic regulatory regimes, rather than the quality of member of a network.

2. The necessity of adopting ISA at European level

To strengthen the regulatory arrangements essential for the successful implementation of international standards, we believe that countries should pay greater attention to the regulatory preconditions. Relevant international organizations must work together to develop a consensus on a comprehensive framework of principles for the regulation of accounting and auditing and to support such a general framework adopted by the competent national authorities.

Challenges in auditing are largely centered around International Standards on Auditing clarified, as their main purposes strengthening the accounting profession and fostering professional standards, the objective of the statutory auditors. The final set of standards clarified, revised and redrafted ISA includes 17, 19 ISA only reformulated and standard quality control ISQC 1[1]. Given the need for a global language, FEE has always supported the adoption of ISAs at EU level, and clarify the translation of international standards using the experience of various professional bodies in adopting and implementing international standards. This point was on the work of the European Commission, which is why it was necessary to clarify the translation of ISAs in all 23 official EU languages.[2]. Thus, many voices could be said that the international audit standards were adjusted to current needs of a wide range of entities. EEF has urged the International Council for Auditing and Assurance Standards Board (IAASB) of IFAC that would be required to publish guidance to facilitate their adoption by small and medium-sized entities. The positive response received from the IAASB in this regard, FEE has shown, once again, as interest in the needs of its members are successful, in the form of concrete actions. We suppose that its mission is to serve the public interest, to strengthen the accounting profession worldwide and contribute to the development of strong international economies by promoting high professional standards of quality, increasing international convergence of such standards and debate issues of public interest that professional expertise is particularly relevant. The role of international standards is to promote

knowledge and use by auditors, the trainees in the financial audit and, in general, all professional accountants in Romania.

In June 2009, the Directorate General for Internal Market and Services launched a campaign [3] which was aimed at consulting the Member States the European Union in connection with the implementation of International Standards on Auditing. Certainly international standards are put on auditors performing an audit in accordance with the requirements of the law. Article 26 (2) of Directive lays down specific conditions for the European Commission audit. It may adopt auditing standards only if they are conducive to the European public good, have been developed with procedures, public oversight and transparency and are generally accepted international. Another condition is related to their contribution to ensuring a high level of credibility and quality of annual accounts and consolidated. In truth, the adoption of international standards clarified questions asked:

International Auditing Standards meet the requirements above?

Their european adoption benefits enough?

For the purposes of demonstration of the conditions for adoption of international auditing standards at European level, the European Commission refers to the IAASB, current government, which has reached a certain stage, that could justify the adoption of ISAs in the EU. Regarding the acceptance of international standards of auditing in Europe, there are far many of the documents which they can draw conclusions that are internationally accepted and it would be best and at European level. The question is whether these standards should be accepted directly, immediately, or they can be expected to be fully accepted and then taken to Europe International. The argument so far as members of IFAC (professional bodies, networks and audit firms) have played an important role in ensuring the widespread use of international auditing standards. More than 100 countries are using international standards or those that derive from these national. In addition, more than 20 major networks of audit firms were included in their audit methodologies to clarify these standards and develop an appropriate quality control policy ISQC 1 standard, since December

2009. We believe that the adoption of quality control standard across the EU ISQC1 encourage fundamental principles of governance in audit firms. Quality assurance is the primary way to show users of the auditors that the auditors are operating at a level consistent auditing standards and ethical rules. We go ahead and mention that a growing number of independent audit regulatory authorities were established in the world with the responsibility of performing quality inspections on work performed by audit firms. This is true both for the EU and countries such as USA and Japan. Moreover, many public authorities, including audit regulators in Australia, Canada, China, South Africa, Netherlands and United Kingdom and Ireland, have adopted the ISA or made public their decision to converge their standards to ISAs. Until now, some countries have announced clarified ISA convergence or adoption, but others have either done this convergence but have not submitted implementation or do not recognize the ISA (USA). Other countries such as Japan, have accepted the ISA standards, but without requiring the audits in the country.

Article 26(2) of Directive 43/2006 provides the option on the applicability of international auditing standards within the community, but does not contain any obligation to make the international standards set by a standardization body. Therefore, modify the standards already adopted if they fail to meet expectations regarding the proper procedures for international acceptance or general European interest. However, the Commission currently does not see what factors might justify a modification of the clarified ISAs. In the same vein, the role of the EU member states is essential . If international standards should be adopted in EU countries would suffer a series of changes in this respect .

I took the example of a number of states and present the main implications for the implementation of ISA [4].

Table1. Implications by implementing International Standards on Auditing

Country	Implication
Austria	The introduction of four new standards: ISA 540,610 620, 720

France	The introduction of new standards : ISA 220 260, 402, 550 and a ISQC 1
Germany	The adoption of ISA in the EU would not make any fundamental change to the required standards IDW
Italy	Possible extension of the use of ISA developed by the national securities regulator - CONSOB Introduction of quality control standard ISQC 1
Netherlands	No fundamental change in how audits are now conducted in accordance with national standards Introducing a standard ISQC 1
Spain	The introduction of three new standards ISA 260, 540 and 550 ISA 250 would limit the choice of auditor report if a company fails to comply with laws and regulations The auditor would be more flexibility to use an expert
Sweden	The adoption of ISA in the EU would not make any fundamental change
Poland	Professional standards are based on the same principles as the ISA, for matters not included in these standards, the auditors use ISA Introduction of quality control standard ISQC 1
UK and Ireland	Elimination of differences that exist between national standards and ISA 200, 210, 580, 600 and 620 Making amendments on quality auditing standards that apply to ISA 450, ISA 510, ISA 570 and ISA 720

Source: http://ec.europa.eu/internal_market/auditing/directive/index_en.htm

In accepting the international audit standards in Europe, also important in terms of investors, they can have the audit reports indicate that the audit was conducted in

accordance with applicable national standards or international standards.

In this situation we believe that reliance on audit reports could be improved if investors know that the EU uses a single set of international standards.

Regarding the implementation of international standards of auditing in the EU, a significant majority of organizations in different countries, support the application of ISA for all statutory audits of companies and small businesses that require an audit. Below ISA adoption, based on data submitted by them: professional auditors, users, public authorities, preparers and other categories[5].

Figure1. Graphic representation of the categories of users adopting ISA

Source: http://ec.europa.eu/internal_market/auditing/index_en.htm

It is found that 100% of public authorities, 96% of professional auditors, 80% of users, 50% and 33% of the junior category „Others” are in favor of adopting international standards on auditing.

Representatives of BDO, a large international network of audit, said they support greater convergence in a number of areas that would facilitate the provision of audit services across the EU, such as supervision of audit firms, the independence rules, schemes responsibility, saying that more than 40% of total turnover worldwide is made from EU member states companies. Next, they showed that adoption of international standards in Europe will

enhance audit quality throughout the EU and abroad and facilitate the practical difficulties encountered in audit. BDO has agreed to include in financial statements audit procedures, and clarified ISA standard ISQC1 quality control, because they reflect the idea of “reasonableness” and “soundness”, to eliminate gaps created between expectations and reality and to strengthen audits in pertinent current business environment. “It is difficult to approve the adoption of international auditing standards in the EU, without adopting the standard and quality control ISQC1”, stated representatives.

BDO audit network backs European Commission, showing that indeed the international audit standards meet the requirements of article 26(2) of Directive 43/2006.

The representatives of the ICAEW, the Institute of Chartered Accountants in England and Wales and supports its adoption of clarified ISAs at EU level for all EU statutory audits, which I believe they were developed in the public interest in a rigorous and transparent process. As we all know the financial crisis has highlighted the responsibility to ensure that market participants may rely on a high quality audit. Thus ISA adoption should be considered as one of the priority measures to restore confidence in the underlying economic recovery.

When asked for the audits should be implemented ISA: for auditing the consolidated accounts of listed companies (IFRS accounts); for the statutory audit for all companies except small business audits, where member states would be free to choose which standard should be applied to audit, for the statutory audit of all companies, including small businesses that require an audit? both institutions have opted for no.3 version, showing that this is the right action to serve the public interest and provide benefits ISA internal market.

Examples may continue, the conclusion being that many countries, both EU and non EU encourages convergence to International Standards on Auditing clarified.

European and international demands for integration, EU member states will require statutory auditors and audit firms to carry out statutory audits in accordance with

international auditing standards adopted by the Commission. An audit conducted in accordance with international auditing standards and ethics, under conditions of independence, integrity and professional competence, can bring many benefits to institutions, companies, financial systems and supervisory bodies. The Commission advocates a broad debate on the approaches to be made to ensure that both audits the financial statements and audit reports for purpose they were created.

AICPA and FASB have developed several useful recommendations for the auditors and those responsible for financial reporting and "Considerations about the entity ability to continue working with the principle of continuity", "The economic crisis: financial reporting and auditing considerations".[6]

In turn IFAC and the IAASB has issued several drafts guidelines for interpreting and amending the existing auditing standards : Audit Considerations in Respect of Going Concern in the Current Economic Environment; Challenges in Auditing Fair Value Accounting Estimates in the Current Market Environment si Report on the Financial Crisis [7].

Regarding the integration of international financial audit requirements of Romania, CAFR as a full member of the International Federation of Accountants and the professional body that organizes, coordinates and authorizes financial audit work is carried out in Romania, aimed primarily and the responsibility to coordinate the translation into Romanian of the International Standards on Auditing and Code of Ethics, to promote both knowledge and use by auditors and by trainees in financial audit, and other regulations as authority issued by the IAASB in continuing to engage in Compliance Program IFAC member bodies.

3. Impediments convergence ISA

What would change in the EU Member States if there was a single set of international auditing standards?

Would be a question I could answer in that the introduction of international auditing standards should be clarified to eliminate, to a large extent, issues related to :

- Misunderstanding of what this standard, we ask them and what adoption means
- False understanding of the actual gaps in the standards implementation and real challenges facing
- Disputes that arise between national auditing standards in different states and national law and the requirements of ISA
- Differences with a negative impact on efforts to monitor compliance and enforcement and legal framework
- Lack of adequate mechanisms to guarantee the national authority for the international audit standards
- Scope of inadequate international audit standards

There are inherent limitations on the ability to perform a proper audit of many smaller entities because of the ability of managers to circumvent controls, and because many countries have only limited capacity in terms of audit. Application of ISA to excessive numbers of firms always leads to problems in terms of general compliance.

- Failure users of financial statements, not the special negotiating leverage, you can determine if those who have prepared financial statements complied with appropriate standards, be able to understand the actual levels of compliance or to exert pressure for improvement, thereby reducing the motivation to comply with standards for those who prepare financial statements and auditors
- Inefficient use of resources, setting standards nationwide and worldwide, and subsequent inefficiencies caused by the fact that audit firms and their customers must adhere to several sets of standards
- Closing compromise when setting the standards, because of undesirable political influence and lobbying, the lack of detailed rules and areas not yet covered by international standards
- Robust application of international standards, which may not be perceived by certain influential stakeholders as being in their interests
- The distortion of public policy decisions that will not be for the benefit of the wider economy
- Failure mechanisms for cost allocation because of the problems of ISA implementation of inequity that are often

associated with the financing of public money

- Public financing, which may not constitute a viable alternative because of demands on resources confluctuale modest

4. Conclusions

It turns increasingly need to implement, both European and international, continue development of International Standards on Auditing, professional ethics, accounting education and public sector accounting, all of which relate directly to the public interest. We believe that conducting an audit in accordance with International Auditing Standards involves compliance by auditors to audit all relevant standards, understanding their correct and full text of the application. The importance of successful implementation can not be overestimated, and the implementation effort required should not be underestimated. Therefore, efforts are needed both at the level of regulators and members of IFAC, and the auditors.

As regulators and supervisors must complete statements and regulatory policies and enforcement of standards, to develop or update national training programs. Auditors and audit firms need to overhaul the system of quality control, audit methodology, manuals or software used by the company, to develop or update their trading programs and update programs and audit procedures.

To implement the clarified ISAs, requiring a period of stability in terms of standards. Thus, in the coming years IAASB not need to issue other auditing standards.

Continued progress in audit policy will require commitment and cooperation of all stakeholders at national, european and global. All market participants at national, European and global level must think hard lessons of the past two years and be ready to take the necessary measures to ensure the consolidation of economic stability and long-term sustainability.

Adoption of standard quality control ISQC1-part of the international audit standards could provide public oversight systems of EU Member States a common standard, to be assessed against the quality control systems of audit firms. It is necessary that control should be standard part of the adoption proceeding because ISQC1 and ISA are interlinked. Currently in Europe the situation is analyzed exceeded the state to accept the International Standards on Auditing, as was the case of IFRS, but I think we should consider adopting such an impact for all stakeholders. Commission reflects on the timing and manner of introduction of ISAs in the EU. Entering can be done through legal instruments binding or binding.

Most organizations from various countries have desirable convergence with international standards on auditing starting with the 2009-2010. However, they said they need time to prepare such an implementation and that at that time, 2009, and currently this is not possible. The term might be suitable in the opinion of some, the years 2011-2012, in the opinion of others, would be much later period.

Emphasizing the Role of Financial Audit by World Financial Crisis

Țugui Valentina
"Valahia" University of Târgoviște
valentina.tugui@yahoo.com

Abstract

It is appropriate that the role and scope of audit to be made and investigated in the general context of reform of financial market regulation. The audit, along with corporate oversight and governance, should contribute heavily to financial stability, because its role is to provide a guarantee as to the truthfulness of all corporate financial health.

Auditors have been and will remain promoters of transparency, the reality of information, of ethics and of professionalism.

It is therefore important to understand, learn from the current economic environment and build a stronger profession. Auditor role is extremely important because it can contribute substantially to improving the quality of management decision process, by providing a dynamic balance of information, including those of financial and accounting can have a special significance.

Key words: financial audit, independent auditors, fraud, corporate governance, crisis of credibility

J.E.L. classification: G01, F36, M42

1. Introduction

The objective of financial statements is to provide information on the activities of an enterprise, useful to a wide range of users to make decisions. If we make a correlation between that goal and that of a company (for profit), we can say that financial statements should be formalized information to answer an efficient allocation of resources in their activity.

Currently, international policies on the definition, recognition and evaluation structures in the financial statements required by the general framework for drafting and presenting financial statements are detailed

and complete for each component of financial statements by IAS 1- Presentation of financial statements. Standard mainly to clarifying the elements to be presented in financial statements, the degree of detail or restriction of such information or component must provide certain information by which a company must consider when preparing financial statements.

We can summarize by saying that financial reporting normalized by IAS/IFRS is circumscribed by the minimum of formalized information and try to pull the financial reporting of a universal pattern used. By detailing all of the mandatory information in the financial statements, European directives are written down in the opposite side, the maximum intelligence, with strict observance of a typical financial reporting for unification in the EU [1].

The overall financial audit shows why the audit is considered a discipline that comes from practice, which seeks solutions to practical problems relevant, based upon theories, postulates, concepts that provides explanations in order to achieve concrete objectives.

Hence the role of the financial audit to certify financial statements through their professional accountants recognized by the public as giving credibility to these information. Since it does not provide accounting information at a time only one representation of reality, it is important that professionals have the endorsement of confirming that, at that moment and the restrictions imposed, this representation is much closer to the real situation. For auditors, the information system is the main source of information, but also one of its objectives. In fact between the message sender is interposed accounting and business users of financial auditor. The purpose of the auditor work is to restore trust between producers and consumers reasonable accounting information. Trust is in our

opinion one of the most important resources available to an economic entity, with capital and management. Thus, auditors can help protect the interests of different categories of beneficiaries of accounting information, when they take economic decisions.

The importance of auditing is to enhance the credibility of financial accounting information in financial statements for the future decisions of users of information [2]. Verification of financial statements that are made by an independent auditor, a professional, with great moral qualities to the completion of one of the qualities of accounting information, namely her credibility. For a company, and an audit is critical to the overall financial situation to evaluate a specific accounting. Critical assessment of the financial statements is made by an independent professional who must fulfill their mission without regard for possible conflicts of interest existing between external users of information and the audited units.

The financial audit is a complex activity that can not be regulated in detail, can not be established universal recipe that can be applied. For the situations faced by an auditor are very different, it :

- audit to consider the rules and fundamental principles that focuses its activities
- audit procedures appropriate to use their trial on a case by case basis, determining that the financial auditor reasoning to be raised to the rank of professional norms
- understand the economic, social and institutional environment in which business is conducted audited
- to comply with the requirements of institutional and business environment in which it operates

Auditing profession has developed due to needs imposed by business, occupying an important role in business environments. Auditor can not therefore be regarded as a mere clerk, hamper his work around professional reasoning involving complex professional training, ability, sense of responsibility, independence, professionalism, etc. The power of decision must be coupled with an exceptional personality, so it can resist any external pressure might change the opinion of the detriment of truth.

The auditor role is also to bring in extra security that accounting information was obtained, treated and presented in accordance with the standards, national and international accounting principles.

2. Understanding the role of financial audit

Financial and accounting audit role emerges from responses to the question :

For those who are in demand auditing?

The existence of an audit request may be explained by audit purposes, namely:

- audits provide assurance that the product is audited in accordance with the conceptual framework of accounting (principles, norms, rules, criteria)
- audit check how much internal control is adapted to specific enterprise, and operates effectively
- audit establish regular monitoring of the enterprise control procedures to ensure that it covers all activities

Public opinion believes that the role of an auditor is to detect fraud and error in the financial statements to have primary responsibility for issuing financial statements and to warn in advance about a possible business failure.

In reality, however, an audit is no guarantee of solvency or financial performance. Management, as one who draws up financial statements, is responsible for their content and, although auditors plan and carry out an audit by adopting an attitude of professional skepticism, an audit process does not guarantee that fraud will be detected.

What the audit is to instill discipline requisite financial, corporate governance can best and minimize the risk of fraud [3].

Auditor give reasonable assurance that such statements are not tainted by fraud, error, so that information in financial statements can be used in making decisions. This result and the International Standards on Auditing where he mentions that many users rely on financial statements as their main source of information because they are unable to obtain additional information to satisfy specific information needs. Because the information contained in the annual

financial information to meet the needs of all categories of users, they must be understandable, credible, relevant and comparable to what is fair reflection of economic reality image.

If the financial audit quality, then it will have positive effects on the economy, namely: give a true image of romanian companies; financial situations, help to combat tax evasion, increase credibility romanian economy to investors, business partners and system romanian banking. The audit is a key element in providing information on financial market risks. It requires becoming more of a close relationship between audit and functioning of financial markets.

Unable to reach financial stability without strong professional organization, professional accountants are competent, appropriate and effective regulatory framework, transparency and proper oversight of accounting, auditing and financial reporting, improved governance, high quality financial information, financial and economic management sustainability of public resources and a strong capital market thriving small and medium-sized entities [4]. Regarding small and medium-sized entities must take into account their needs and issues when formulating and implementing policies and financial reforms.

It is appropriate that the role and scope of audit to be made and investigated in the general context of reform of financial market regulation. The audit, along with corporate oversight and governance, should contribute heavily to financial stability, because its role is to provide a guarantee as to the truthfulness of all corporate financial health. This guarantee is designed to reduce risks of distortion and, as such, generate cost savings in bankruptcy, which would be supported in parallel by the company shareholders and society in general. The robustness of the audit is essential to restoring security and confidence in the market, helping to protect investors and reduce the cost of capital of companies. It is noted that an audit profession better designed and better market and organized the audit would lead to more effective audits, to reduce the bankruptcy cost and capital cost and increase confidence and protect investors. Audit market has a direct impact on how to practice the profession of auditor. Auditors have been and

will remain promoters of transparency, the reality of information, of ethics and of professionalism. It is therefore important to understand, learn from the current economic environment and build a stronger profession. Auditor role is extremely important because it can contribute substantially to improving the quality of management decision process, by providing a dynamic balance of information, including those of financial and accounting can have a special significance.

In the current economic context, both investors and regulators are interested in detailing the information presented in financial statements. Before including them in the current financial statements, companies must review the above information to determine if they are relevant and not misleading.

Another aspect that can be presented in financial statements is the strategy of a company response to changing economic climate and the effects felt in the past and future activity.

As the financial auditor profession has a key role in determining the proper course of economic activity entities, both supervisor and auditor to express a common interest in the application by credit institutions and non-bank financial institutions accounting policies are appropriate. Therefore, a continuous dialogue between supervisors and auditors could include important aspects of the audit and accounting issues off.

The audit is part of the operational mechanisms of the economy and capital markets success depends on it if there is a stable and competitive market for audit.

In any case, there is plenty of evidence showing that the public and other users of financial statements do not understand the role of an audit.

A "therapeutic" understanding of the role of the auditor may be a major element to represent the "compass" to guide management. Governance entity and the auditors communication with other users of information from audit reports can help the effort to overcome the current economic situation. And persevering dialogue with business is likely to provide a better understanding of the meaning of audit, specific activity competitive economy, the businessmen, entrepreneurs can find qualified support, relevant and objective [5].

3. Consolidation the role of financial audit

An issue that needs to be reviewed is the "discrepancy in terms of expectations" between what the public and users of financial statements believe that is what the role of an auditor and the audit profession to understand the role of the auditor.

It is certainly in the interest of both the audit profession and the public to make sure the gap in terms of expectations is reduced as much as possible. Possible ways to act include :

- 1) Establish clear role, methodology, scope and limitations of audit extend the role and responsibility
- 2) Extend the role and responsibility of auditors in the areas of fraud detection
- 3) Continue strengthening the independence of auditors that audit committees

It is unclear whether auditors are truly detached and watching with a critical eye of a company financial statements when the same client company is a current or potential, without regard to the audit staff that performs auditing firm that. Business climate should allow independent auditors. However, some doubts about the possibility of independence in the current climate and stresses that although certification of company accounts show their strength, in reality they were financially unstable.

Threats to this independence should be minimized. If such threats can not be minimized to an acceptable level, then the auditor should consider their ability, in order to continue the activity.

Threats to independence may arise in these circumstances [6] :

- the auditor is personally interested in – eg. can lose is afraid that the audit fee
 - intimidation - the auditor may be intimidated by the dominant or aggressive management
 - long association, if the auditor had a long association with the client, it may become more sympathetic to the customer
 - carrying out non-audit work and audit later - threat autorevizuire
- 4) Confidence that stakeholders have in the audited financial statements

This is why we try to understand why there are discordant between expectations and reality in terms of interested parties regarding the subject and audit methodology.

- 5) Remove the possibility of a systemic risk because of high concentration of the audit

There may be significant consequences for the financial system in general, if one of the major audit firm has a monopoly on the world market audit, would close.

It is recommended to avoid any interruption in services offered by the major audit firms to prevent their collapse. At the same time it must increase the size of smaller audit firms, tackling barriers to market entry and increase fluidity by creating a European market.

- 6) Risk-based approaches (eg. risks of material misstatement in the financial statements) which are much more efficient
- 7) Strengthening the role of audit committee oversight of risk management, understanding and reporting processes, risk management, and improve its communication with management
- 8) Understanding and enhancing the role of internal audit in risk management process and its contribution to improving processes and internal control environment of business
- 9) Process improvement tools needed to improve risk management and corporate governance
- 10) Role played by supervisors and the effectiveness of national surveillance
- 11) A real market potential for internal audit and eliminate barriers that currently make a market in the predominantly national audit. In this context, the concept of the european passport for auditors to be explored in more depth.
- 12) Specific needs of SMEs, to ensure proportionate application of audit standards
- 13) Global context. The audit is a global market in which companies operate as global networks, it is important to coordinate efforts by states worldwide.
- 14) Provide more information on the risks, judgments and estimates
- 15) Consolidation professional skepticism

Professional skepticism [7] is of major importance in the audit process, auditors should be aware of:

- Audit evidence that contradicts other evidence
 - Information that question the reliability of audit evidence
 - Conditions that may indicate a possible fraud
 - Circumstances that suggest the need for additional audit procedures required by the ISAs
- 16) Request by the auditors, users, information useful for them
 - 17) Provide educational services in an audit regarding the education of the public and users of financial statements on the limitations of audit
 - 18) A better communication between auditors, audit committees and stakeholders inside and outside that the audit report
 - 19) Align the auditor role more public expectations
 - 20) Provide assurance on financial statements based on historical data

Communication between auditors and users could be improved either by extending the potential scope of the audit (according to include information about risk management, internal control, corporate governance) the audit was to consider and comment on the financial assumptions underlying the business information.

The auditor should not issue opinions on financial statements, which only refers to information in the past but to look at those financial projections and are indicative of the future viability of the company.

Another way to improve communication might be possible modification of the audit report or by widening it, or by including information that is currently in a letter to management or the audit committee, to which investors have no access.

Consolidation the independence of auditors and audit firms that can be done by the elements [8]:

- compulsory rotation of audit firms and partners
- extending the prohibition of rendering of services unrelated to audit
- whether remuneration, remuneration of the auditor, during the engagement to be made by a third party

- limiting the proportion of fees that an audit firm may receive from one client to audit firm total revenue
- consolidation corporate governance and organizational requirements
- consolidation the role of auditor of a group

Financial auditor can positively influence corporate governance?

The answer is that the applicable professional standards, financial auditor has an important role in implementing the principles of corporate governance in the entities audited by:

- understanding by corporate officers charged with governance of their responsibility for: preparation of financial statements in accordance with the applicable financial reporting, internal control so that financial reports are free of material misstatement
- understanding by those charged with governance of the corporate auditor responsibility to express an opinion on the audited financial statements
- communication to officers charged with the significant corporate governance issues: policies, procedures and inadequate accounting practices applicable reporting framework, internal control unorganized or poorly functioning
- highlighting the risks arising from accounting estimates and disclosures on the value of assets, liabilities and equity inappropriate
- consideration by the financial auditor of the audited entity and integrity management of its employees [9]

Also to clarify some aspects of the relationship between financial auditor and internal auditor, the report of the internal auditor, the audit committee and auditor.

The crisis revealed deficiencies in the audit sector. They should be well analyzed found ways to remove the deficiencies and improving the audit sector activity.

Following the financial crisis in particular, has emerged the question of whether the role of auditors can be strengthened to reduce future any new financial risk.

4. Conclusion

The audit function has become a universal feature that is gained through organized and must execute all entities and all levels.

Financial auditing profession has a key role in modern economy, the quality, accuracy and reliability of the information and findings contained in audit reports depends decisively to adopt decisions on the purchase of shares or making important investments.

The content and status of their work, auditors may have an essential contribution in revitalizing the economy, business confidence. Thus we can say that we need strong and fully independent audit. Expense that the government make an audit companies for a contract he can have a full justification, businesses can add value to the extent that auditors do their job with competence, independence and objectivity, audit report so that it develops to provide credible assurance, both corporate governance, entity-investors and partners, creditors, financiers, customers, on the quality of management of that company, the seriousness, fairness and viability of the business .

The audit is relevant and important, as such, it is possible that the role of professional auditors to be necessary to evolve with the changes that will occur while. The role of audit is not static - it should evolve evolve as accounting, organizations and society. It must be sufficiently studied [10].

Increasing importance of auditors; work tends to increase in future due to the contribution that they should bring it along with the entities in Romania implementing International Financial Reporting Standards for financial statements.

If the initial purpose of financial audit was the detection of fraud, it has evolved over time, so that now serves to certify the accuracy of the information presented in financial statements and compliance with IAS/IFRS. Truthfulness of financial statements is essential for all financial actors, who must rely on data.

Although the auditor role is not to predict the future, but to ensure that the financial statements of companies provides a clear and accurate picture of the performance of a year,

it is possible that auditors ought to be skeptical of estimates made by management financial statements, however this would have seemed difficult [10].

The fact that current events in Romania, Europe and the world questioning the credibility of dedicated auditors and results of social work and create more and more doubt on the credibility of financial reports of companies.

Thus, we believe that auditors may be part of a new identity crisis of the entities, the corporate governance of companies, which is why we question :

How can auditors, to overcome the crisis of credibility, so do not be undermined public authority?

I think a possible answer to this question could be a unified and coherent approach to the activities managed by the profession, auditors working for the results to remove them from the scope of the blame for the current crisis and other shortcomings of the Romanian and European public life that participate.

Abstract

Currently, on international level, operates a variety of companies. From all of these, the transnational corporation represent particular interest, being designated as an "entity-key of global economic activity, a creative net worth to devote a large proportion of global resources needed to sustain economic growth processes. The new trend in the STN sites emphasize efforts to promote corporate social responsibility that contributes to change the attitude of many corporations and individuals working for them. Company efforts are visible in contributions to community development and environmental impact. Corporations want to impose their own standards of development which reflects some positive attitude towards regulations that support behavioral codes which they argue. Globalization has opened the way for limited progress, offered alternatives to local development, has generated deep changes, n dimensional complex with sometimes unpredictable consequences on economic development and socio-institutional

Key words: globalization, transnational companies, social responsibilities, development

J.E.L. classifications: F23

1. Overview of contemporary reality

We all know and live a more difficult period of economic history, that of a global crisis. If until now almost all economists analyzing the phenomenon of rising global economic boom in globalization today, the same economists studying the phenomenon of global economic crisis, încearcând roots to find them, analyze them and to carve another route the great globalization. Liviu Voinea after witnessing the greatest economic crisis after 1929 and the systemic failure of capitalism, the profession of academic economics and the economy as understood and taught her all over the world. [Voinea, 2009].[1] Few were those who foresaw the crisis, but to no avail, because there was no time to be listening, indeed have been sidelined until reality gave them justice. The crisis has actually gone from securitization, sub-standard loans, but its scope of coverage was much higher. In other words, the crisis in the U.S. went out there with roots as determined by excessive investment in innovative financial derivatives, the chase after reporting profit while being driven by the phenomenon of deregulation and corruption. The next step of the crisis was made in Europe, where penetration and expansion mechanism was different in the West against East. Western Europe was transmitted mainly through toxic assets of financial institutions in East and was transmitted by reducing abrupt current account deficit financing. Romania, in this view can be joined Eastern economies as Hungary, Bulgaria and the Baltic countries.

2. Challenges in corporate governance

Currently, many businesses and massively expanded marketing, supply and production in the global market, managing to create global structures which allow them to quickly transmit information and ideas from other corners of the world. Businesses face a competitive environment than larger and more complex than in the past. Some believe that the world is run by giant companies, megacorporații those who are not only interested to sell as many goods on international markets but also to purchase, to produce various components and materials from or abroad. Therefore, transnational firms have to coordinate the functional operations across state borders by a rapid transfer of knowledge, helping them to increase efficiency. [Pandelica, 2007][2]. To meet the challenges of business globalization, many companies form strategic alliances and other business funcționează even competing. Mergers, acquisitions and strategic alliances are logical and inevitable consequence of competition in a global economy without barriers, and becoming more integrated. We are witnessing a globalized economy combined with information technology, which enables TNCs sites to strengthen the control on a scale that has not been possible until now.

Corporations today are open to everything new, able to respond rapidly to new information and changes in international markets, as these corporations adopt strategies based on the implementation of learning behavior. Equally important for TNCs sites is the ability to keep pace with the markets, they can adapt and respond to competition, may produce goods in conditions of efficiency, but also understand the phenomenon and to protect local companies, which is important to strengthen local communities both economically and as socially. Many transnational corporations have not done all it would be best to improve working conditions in developing countries. These companies have gradually come to understand one thing that home to them, I understood much more difficult. Providing better working conditions may actually

contribute to increased labor productivity and lower overall costs - or at least limiting their growth. [Stiglitz, 2005][3] Globalization of economy globalization require thought and work, which means the ability understand the world as a single market, the conditions and laws are very different. Manager with a true global mindset is one that has the capacity to adapt to national and regional particularities and which does not distinguish between inland and abroad.

Currently, globalization is contested by everyone. There are complaints about it, but not missing any praise. Globalization can be a force for spreading the good: the globalization of ideas about democracy and civil society has changed people's way of thinking, while political movements leading products worldwide to ease the debt burden. Globalization has led to hundreds of millions of people to achieve higher living standards, also, economic globalization has brought benefits to countries that have profited from it by identifying new export markets and attracting foreign investment. Stiglitz said that countries had benefited most were those who took their own fate and have realized the role the state can play in the development, abandoning the idea is also based on a market capable to solve their own problems. [Stiglitz, 2005][4] Globalization has had beneficial effects on democracy, national elites trying to replace dictatorship with the dictatorship of international finance. Some countries were obliged to markets and international financial institutions to give up their sovereignty, which allowed the capital markets, including speculators whose concerns were short-term economic growth, and long term growth of a country with living standards, to "bring order", telling them what to do and what not to do. For millions of people say that globalization has not brought anything, or even a negative impact because of their moral situation worsened, their jobs were abolished, people become powerless before the force of globalization that could not control, while attending to undermine democracy and the erosion of their own cultures. Growth - including that induced by globalization - will lead to urbanization, undermining traditional rural societies. Retailers that operate internationally and have a great shopping devastate small businesses and communities in which business is carried on those.

Developing countries that have been most successful, most of East Asia, opened to the world, but they did it slowly and following certain steps. Countries have benefited from globalization to boost exports, and therefore to develop a faster pace. They are abandoning the protectionist measures carefully and consistently, when they have created new jobs. These countries have ensured that there is sufficient capital to create new businesses and jobs or even have themselves contributed to this effort. China has eliminated trade barriers not a very long time but at a distance from when already begun to travel the road to market economy, during which has grown extremely fast. However, globalization is just one of many forces that affect our societies and economies. Technological changes have increased the importance of skills in certain markets, so that those who benefit the Synthesis today are those who have or can obtain those skills. Changes in technology may ultimately prove a more important factor than globalization, even in declining wages of unskilled sector. [Stiglitz, 2008][5]

3. Corporate social responsibilities and benefits versus private incentives

Everyone knows the key role of transnational corporations in the globalization process, which is manifested by: bringing the same level of markets, technology and capital to developing countries with production capacity of developing countries. Corporate social responsibility is the obligation of a corporation holding beyond those legal obligations or restrictions imposed by economic, to conduct business so as not to endanger the welfare of local community and to pursue long term goals are to benefit society . A company that falls only within the limits defined by law and imposed by the market to fulfill his obligation strictly social (Social Obligation), while a corporation trying to adapt to changing social conditions is characterized by social response (social responsiveness). Only if the company seeks to assess what is right and what is bad for the company long term

and acting accordingly can say that it shall conduct social responsibility (social responsibility).

From the perspective of socio - economic development of corporate social responsibility, multinational company would have to make the following objectives: to maximize long term profit, not short term, to consider the local community as an interested party, giving back to society through various activities a share in the profits of his operations, to recognize the importance of protecting the environment, to behave proactively to protect, and to encourage employees to behave, and the protection of existing and prospective customers. Corporate engagement in actions of socially desirable long-term without improving market position by increasing recognition and appreciation from consumers. Corporate social responsibility is manifested in four levels of influence. The first level is the work related to standards, quality procedures, as well as harmful emissions and waste management. The second level is the market related to the standards of distribution, marketing and consumption, vendors, business relationships. The third level is the community, influenced by the manufacturing and distribution. The fourth level is public policy that can be influenced by public institutions and social infrastructure. Corporate social responsibility manifests a shift from stage at the option of necessity. So some corporations have specialized departments of social responsibility and 90% of the world's top 500 corporations have ethical codes of conduct. The corporate social responsibility is considered to be more and more corporations as a characteristic of a good business (and some studies show that firms socially responsible record better results in stock, compared to others), for many firms, in terms of management and employees, social responsibility is more moral than the economic. Such a company is regarded as a small community working together to achieve a common goal, ie the big part, cares for others, avoid negative publicity and can receive high-quality workforce that attracts and with good conduct: thus their anjajații simpt better if working for a company is socially responsible. [Stiglitz, 2008]

Unfortunately in this world where ruthless competition manifests itself, the motivations of companies is acting sometimes at the expense of those who have the best intentions. The

reality is otherwise very well thought out and very carefully organized, as all companies, even those that pollute a lot and practicing bad policies to employees, hires public relations firms to their corporate responsibility and their concern elegeze the environment and to the rights of their employees. Thus, corporations are beginning to adopt through image manipulation and learned to support social responsibility even when not practică. Mișcarea for corporate social responsibility is important but it must be accompanied by stronger regulation. Corporations that want to impose higher standards must develop a positive attitude towards supporting regulations that support the behavioral codes and these regulations would protect them from competition without fair play from those who do not comply with these standards regulations would help to prevent market monopolization. [Stiglitz, 2008][6]

Advantages:

If companies are part of the community, the country of origin assume "sometimes" a moral responsibility for actions of their own, without being compelled by law or regulation, this recording some public scurt. Interesele term profits are low the responsibility of government, embodied by adopting protectionist laws.

Disadvantages:

- enormous accumulation of capital,
- moral responsibility is reduced to transnational corporations that operate in other countries (not treat employees and the environment of the host country as it is a home tn).
- serious consequences on society. Developing countries need jobs that create corporations, even if the environment or the workers suffer.
- ability to hide across borders
- move values from one country to another can be done fairly quickly if TNC's, and if a company is bound to pay a certain sum in a country, that amount is sometimes impossible to obtain.
- countries with more lenient / lax provisions in labor law and the environment are most sought by investors in this race to cut costs.

-made strong lobbying by corporations against environmental standards which reduces profits.

-creating favorable legal environment in poor countries.

-influence exerted by TNCs in developing links with international agreements, which led to distortion and greater social hierarchy and private motives.

The conclusion is that incentives are important, and governments and the international community must work harder to ensure that corporate motivations are closer to those of people they influence their actions, especially the least powerful in developing countries development.

If you look to the future, we can see everyone differently, or we can imagine him as we would like to be. The fact is that we make predictions about the future economic situation in light of current socio-political. An overview of the global space shows that Asia could produce strong waves in terms of savings, foreign exchange reserves, growth rates, expansion of exports and the accumulation of new technologies. Corporations in China and India increasingly acquiring more control stakes in other regions of the world, crave global players' roles, and especially the control of exhaustible resources: oil and gas. Thereby Asia by increasing its economic power could alter competitive hierarchies of power would reduce the influence exercised in the West overall space. So, would change the trajectory influences regional alliances would end any other color, international organizations could also be influenced decisions. Another consequence could be linked to control strategic resources that will give a great battle with more or less noise. Besides depleting resource competition was launched worldwide by travel and alternative energy sources, because consumption is increasing due to economic growth especially in Asia and food prices suffer major fluctuations.

To inspire optimism for the future, there should be cooperation, regulation, communication, change among international bodies, eliminating conflicts of interest and prevent future instability. All they can define a different globalization in which we live or where we live, that globalization seen as an open concept that defines the behavior of companies and corporations as an openness to

technological, economic and social progress of the search

Future of transatlantic relations will clearly be indispensable in many point of view of corporate structures, which have the objective of industrial policy, protectionism and not only selectively. If you look inside a corporation, the future would see this: In addition to the essential relations at regional or global, I can say that a corporation and changed priorities, not chasing the market because they have already won, no running even after accumulation, because they had doubts, but rather think how to exploit what they have gathered so far. Next step will be to corporations from my point of view that innovation, recreation and reinvention of the business, continuous improvement and progressive transparency, all started on the long term. To support such projects, corporations need ideas, people able, encouraging processes, principles and courage. Corporations will put greater emphasis on innovation, but the mere process of innovation but on value innovation. This process is based on the stock, which possesses the capability to operate from the inside out, all to create new applications and with it the creation of new businesses. Corporations will have to realize that the price of their assets consist largely of what is in the minds of people they employ.

4. Conclusions

In conclusion, I think of three possible scenarios on the future of corporations. A first scenario would be one in which a not too distant future corporations would come to rule the world, dividing it between them. Thus we live in a world that large corporations would go where it holds a monopoly position. In this context they should have the ability to control and manipulate the market. A possible form of monopoly position manifestare for example control global production levels, limiting its growth amid a trend of consumption clearly leading to a price spike. A second scenario would be to limit the power of multinational corporations in the future.

This could be achieved through legislative measures For instance local or regional trends and anticompetitive practices to limit or restrict the emergence and development of monopoly. A third possible scenario would counterbalance corporate power through incentives and support SME development. Moreover in some particular situations may even proceed to grind or large corporate reorganization in smaller companies, possibly narrower specialized competence in areas that can perform.

Cluster – A Motor of Competitiveness and Innovation in Regional Development

Ungureanu Carmen Doina
Ecological University of Bucharest
carmenungureanu@yahoo.com

Bilevsky Gabriela
Institute of Economic Forecasting, Romanian Academy
gbilevsky@yahoo.com

Abstract

The cluster policies have become an efficient instrument and experience in the field has proved it.

The various approaches to this concept have led to innovative clusters. In Romania, this concept has been approached within the industrial policy since 2008, cluster supporting and implementing through the co-ordination of various instruments being one of the objectives of European Union.

Clustering has already reached more than 50% of the of major countries economies; it serves as a new vector of the world system capitalism development. A. Toffler, citing the example of Italy, called clustering the «new wave» of the capitalism development.

Key words: industrial policy, cluster, regional competitiveness.

J.E.L. classification: O25, C38

1. Introduction

Against the background of global competition, regions and regional companies face the challenges provided by the global market. The competitiveness of a region is not determined by single companies, but more and more by the innovative activities of entire industries and branches. For the economic and technology policy of the European Union and its member states, the regional competitiveness has become the central topic. The main objectives of promoting to these policies are: innovation, co-operation and internalisation. An appropriate way to achieve these objectives is the development of cluster initiatives.

2. The Concept of Clusters

The inventor of the "cluster" term, Professor Michael PORTER [1], defined cluster as "a geographical concentration of interlinked companies and institutions from a certain economical field". From Porter's point of view [2], clusters have the following components:

- Interlinked industries and other entities, such as specialized suppliers and the according infrastructure;
- Distribution channels and customers, complementary product and service providers and companies affiliated as competencies, technologies etc are concerned;
- Linked institutions, such as research institutions, universities, benchmarking organisations, training entities and others.

The New Diamond of Innovation

In today's economic context, one does not only speak about clusters. Often the discussion goes about innovative clusters. Innovation can be seen as a result of interactions between different actors from the innovative systems. The systemic view of innovation was first promoted by LUNDEVALL (1992) and NELSON (1993), and more recently by GUTH (2004). Considering these new ideas, the traditional linear model of innovation becomes less relevant. Learning, trust and social capital turn into foundation piles of this model. The "New Diamond of Innovation" Model was developed by GUTH, M. (2004), taking into consideration the competitive advantage theory of PORTER and the individual and institutional learning concepts (Research activity was financed by Hans Böckler Foundation, Germany, www.boeckler.de)

The Triple Helix Model

All theoretical and historical considerations revealed so far, concluded into today's paradigm of the "triple helix" as a model for successful cluster initiatives. According to this model a cluster developed, must consist of following categories of actors:

Figura 1. The Triple Helix

Adapted from the „ Triple Helix Model”, Etykowitz, H., 2002

- Universities, research institutes – as suppliers of innovative products, technologies, processes and services;
- Industry, especially SMEs – which represent the innovation demand and in an ideal case they should determine and absorb the offer mentioned above;
- Authorities responsible for the process facilitation (ministries, regional authorities, etc).

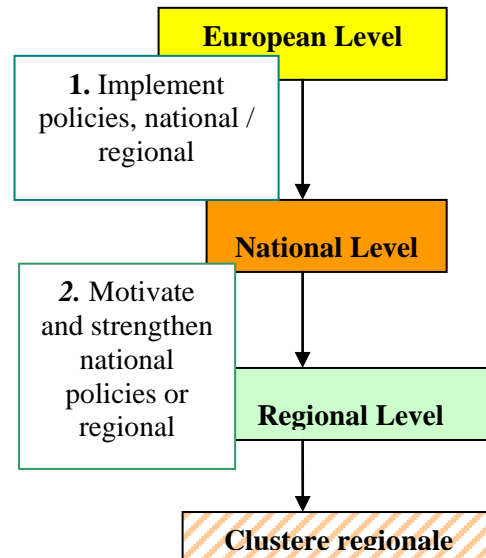

From a different view, **regional clusters** are a concentration of business firms, independent service firms, including their suppliers, the knowledge, technology and knowhow creators (universities, research institutes, engineering centres), the coupling of market institutions (brokers, consultants), financial institutions, industrial and social infrastructure, as well as consumers who interact with each other in a single chain of value creation, while closely being related to a specific region (in this case, an administrative unit is not a clear region boundary).

3. Cluster Policy

Some cluster initiatives emanate bottom-up, whereas others are inspired and mainly financed through a national or regional cluster program. The organization of cluster construction at

national, regional and local levels differs widely across nations.

Figura 2. Level Actors Involved in Cluster Construction

Adapted from the „Clusters – Balancing Evolutionary and Constructive Forces”, Örjan Sölvell, 2008

Types and contents of cluster policy vary considerably from country to country. As a rule, three types can be distinguished:

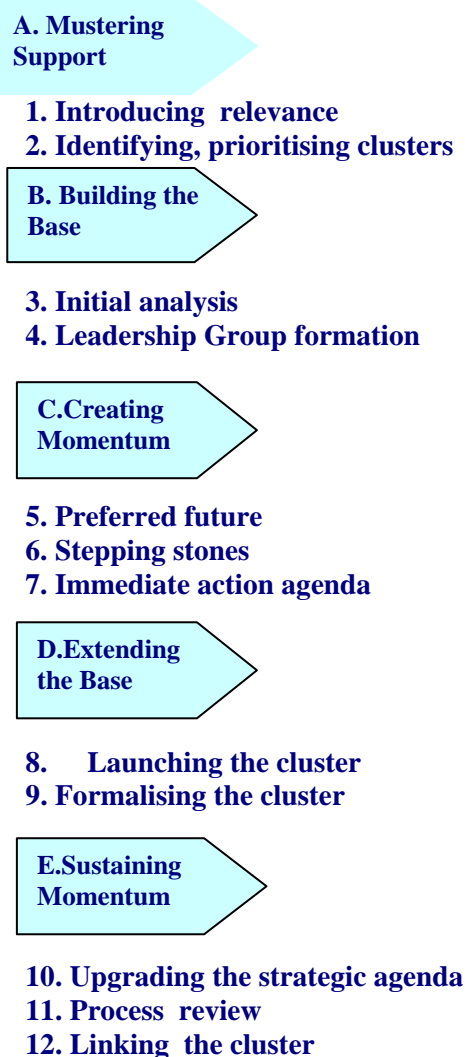

➤ A first type deals with the strengthening of `triple helix` relationships, particularly between industry, research and government agencies, such as regional development agencies or science and technology agencies.

➤ A second type focuses rather on R&D co-operation between companies and between companies and research organisation.

➤ A third type concentrates on encouraging co-operation among companies, regardless whether these collaborations take place with R&D-institutions or are carried out either horizontally between competitors, or vertically along the value chain.

The cluster development process can be broken down into five broad phases, containing 12 steps

*Figura 3. Cluster Development :
Five Phases, Twelve Steps*

Adapted from © Cluster Navigators Ltd 2004

While cluster development must be private-sector driven, government agencies have a core partnership role to play in the process of cluster development.

4. Benefits of Cluster Initiatives

The prospect of potential benefits from cluster initiatives for companies and regions encourages governments and other public actors to launch cluster promotion policies. In general, a well-developed concentration of related business promotes three important activities:

- Increased productivity (through specialised inputs, access to information, synergies, and access to public goods),

- Faster innovation (through cooperative research and more intense competition),
- New business formation (filling in niches and expanding the boundaries of the cluster map).

Cluster initiatives help regions govern their economic development and recruiting efforts. It also encourages communities to refocus their efforts on existing industries.

Strong domestic cluster initiatives also assist the regions in attracting foreign investments. As leading platforms for their industries, clusters are able to attract national and international key players. In fact, foreign-owned companies can enhance the leadership of the cluster and contribute to its upgrading.

Clusters are strongly project-oriented, their activities being often implemented within these projects.

Promoting innovation, which is crucial to the success of regions in general and industry in particular. Today, the enhancement of economic globalisation and the increasing use of information technologies put massive pressure on the acceleration of innovation processes.

Promoting co-operation, means fostering collaboration between industry, with a special focus on small and medium-sized enterprises (SME's), research institutions and academia. Supporting cooperation projects increases the rate of innovation processes and the technology transfer from R&D-institutions and academia to industry.

Fostering internationalisation, especially for small and medium sized companies do not possess enough resources and know-how to enter new markets. Therefore, internationalisation has become an essential factor for companies and regions to succeed in the global competition.

The Aho report gives as well a perspective of how clustering efforts can help regional development:

“Clusters and, more generally, regional agglomerations are often at the core of innovative development. It is widely recognised that new firms thrive in the proximity with other companies, investors, educational institutions and research centres afforded by clusters particularly in the presence of world class academic institutions. Mobility can be maximised when there is a local labour market that allows regular flows

of people from one situation to another, with accompanying diffusion of knowledge. As well as the greater opportunity range it is clear that barriers such as the need to move house or schooling for families are removed. However, it also emphasizes that minimising such barriers more generally will create a more functional society.

It is important to ensure that clusters are defined in terms of the new market and knowledge relationships needed for emerging sectors to thrive. It is even counter-productive to reinforce traditional sectoral clusters as these may inhibit the necessary mobility. Firms in traditional sectors are far more likely to find innovative growth by forming new linkages and applying new technology to their existing products and services. This can be facilitated by opening the clusters to cooperation with and learning from other clusters in the same or other sectors.

In order to improve human, financial and knowledge mobility in terms of human mobility, it is important to observe if the clustering efforts have resulted in the attraction of professionals from other areas of Europe and the world, creating a concentration of excellence in the field, or rather has given a label of "excellence" to the already existing pool of talent.

In terms of financial mobility, the cases look at whether the clustering efforts have been effective in attracting new financial resources to the area, willing to invest in the more innovative strategies and projects, or are just obtaining subsidies to already committed traditional investments.

In terms of knowledge mobility, have the clustering efforts lifted barriers to facilitate cross-fertilization among clusters, or are they just reinforcing the institutionalisation of traditional pools of knowledge (for example: through the creation of inappropriately defined research institutions).

The companies within the clusters are more innovative than those outside it, protect their brands and industrial copyright better than those outside it, provide more jobs, pay higher taxes and pay their employees higher wages.

Of the total European labour force, 38% is employed in entities within clusters.

The objective of the Europe 2020 Strategy is to promote smart, sustainable and inclusive

growth in Europe, and clusters are an important element of this strategy.

At the European Cluster Conference (September 2010, Brussels) was the presentation and further discussion of the final report of the European Cluster Policy Group (ECPG). This report calls for an improved coordination between the different EU initiatives in support of clusters and proposes that the "focus of cluster programmes needs to be shifted from capacity building and compensation for poor performance towards a clear orientation on excellence, focusing on clusters with the ability and the willingness to upgrade in the face of global competition and ensuring the consistent provision of public knowledge infrastructure to support them."

The European Cluster Conference has been the scene of launching three new support services for cluster stakeholders in Europe:

- Club of Cluster Managers'
<http://www.cluster-excellence.eu/club.html>
- European Cluster Collaboration Platform
<http://www.clustercollaboration.eu>
- European Cluster Observatory
<http://www.clusterobservatory.eu/index.html>

5. Conceptual Consequences for Romania in Innovative Clusters

For the Romanian reality the triple helix way of thinking needs to be modified to a "Four clover" model, where the fourth actor is being represented by catalyst institutions: service providers in the field of innovation and technological transfer, centres for technological transfers, chambers of commerce etc. Amongst these we can further differentiate between specialised service providers (experts in the industrial field of the clusters) and generalist consultants dealing with management, communication, project generation etc. It is obvious that the actors within this model have different contributions and interests, which have to be harmonised (Mapping Report GTZ, 2010).

Clusters are in compliance with the modern approach on « open innovation » which depends on the interaction between a strong academic research (universities),

dynamic entrepreneurship and the risk capital availability (private environment), as well as a supporting political framework (public administration).

6. Cluster Policy in Romania

-Industrial Policy document and the related Action Plan (2010-2013) with a specific chapter on cluster policies (www.minind.ro)

-National Program for increasing the competitiveness of industrial products (activities dedicated to clusters)

-Regional Development Strategies focused on clusters and networking

-Project INOVCLUSTER launched by the Ministry of Economy Trade and Business(2008-2010)

-Collaboration with GTZ from Germany for the « Romanian Cluster Mapping »

-Clustinova project and trans-borders cooperation projects

-Exchange of best practices with Hungary, Croatia, Poland, Turkey, Sweden, France, Germany, Slovenia, Italy-Ministry of Economic Development and IPI-Institute for Industrial promotion, Serbia, Macedonia etc

-Situation in Romania (Regional SWOT analyses, regional potential for clusters, initiatives, Interministerial Working Group, INCLUD Project-Industrial Cluster Development, INOV Cluster project, Romanian Cluster Mapping).

-Possibilities of financing (private and public funds, European funds, bilateral cooperation etc)

-Main stages in setting up a cluster and registering in the European Cluster Observatory.

In Romania there are 17 innovative clusters (bottom-up) in different areas, in 2010:

- Automotive, a regional cluster in Timisoara and Pitesti;

- ICT, in Timisoara and Craiova;

- Tourism, in Suceava, Drobeta Turnu Severin and Mamaia;

- Agro-food, in Arad, Iasi and Bucharest;

- Electro-technics in Brasov;

- Renewable energy in Sfantu-Gheorghe;

- Silviculture and Wood industry, furniture in Sfantu-Gheorghe and Targu Mures;

- Textile in Savinesti and Bucharest [8]

7. Conclusions

Cluster structures do exist in RO: regional concentration of firms, specialised R&D units and relatively sufficient labour force, but there are problems [6].

Problem 1: Hardly any cooperation amongst the partners

Problem 2: Lack of specialised innovation service providers and at the same time reluctance of RO firms to use external innovation services.

The Agrotourism - a Vivid Chance for the Rural Life

Ungureanu Carmen Doina
Ecological University of Bucharest
carmenungureanu99@yahoo.com

Brăgaru Constantin
„Nicolae Titulescu” University
costinbragaru@yahoo.com

Abstract

The people's desire and need to leave the polluted, crowded and noisy urban areas made them to move to places where they can be closer to nature, in a relaxing atmosphere and without pollution. There has been developed a different kind of tourism that allows tourists to integrate themselves in the rural society.

This is also beneficial to the rural areas where these activities are carried on, allowing them to develop, especially to small localities which have a valuable tourist potential.

Key words: rural development, agrotourism, agrotourism sustainable development

J.E.L. classification: O13, Q01, Q26

1. Introduction

The economic crisis that marked the world in the recent years has also affected, as expected, the tourism sector in Europe. In 2008-2009, the housing component of the tourist activity crossed a difficult period, so that in 2009, the number of nights spent by tourists in hotels and similar lodging facilities fell below the level reached in 2006 (Graphic 1).

Good news, however. In 2010, after two years of negative growth (during which only residents were the most important guests), there has been a tourism revival, so that the number of nights spent by non-residents this year compared to 2009 was higher (5.1%) than the number of nights spent by residents (+1.1%). [1]

Graphic 1. Total nights spent by tourists in hotels and similar lodging facilities

Source: Eurostat, Statistic in focus, 6/2011

In Romania, however, the change of the percentage of the number of nights spent in hotels and other similar accommodation facilities, for the same period of comparison, in 2010 compared to 2009, expressed an increase by + 3.2% for non-residents and a decrease by -10.9% for residents.

In the 27 European Union countries, in 2010 compared to 2009, the domestic market recorded the largest contraction on tours (-1.1%) compared with the number of trips abroad (-0.7%).

In terms of journey times, the longest ones (four or more nights) have decreased by 1.7% compared with the short ones (maximum 3 nights), where there was a decrease of 0.3%.

2. Agrotourism in Romania. Concept and evolution

The agrotourism (or the "Tourist adventure", as it was called, at the beginning, round the year 1840) first appeared in the

European alpine countries, namely in Switzerland, in the Château d'Oex area.

In this area, the English discovered wonderful mountain scenery, mountain waters, rich meadows with herds of cattle, welcoming people.

In *Romania*, the foundations of the agrotourism have been institutionalized in 1972, when the Ministry of Tourism selected 118 representative rural settlements, which were to become part of the national and international tourism (OMT 297/1972).

The *agrotourism* involves the stay at a peasant lodge - hostel, farm etc. -, the consumption of household agricultural products obtained in the respective lodge, that participation, in a greater or lesser extent, in specific agricultural activities [2].

The agrotourism includes two large components:

- the tourism industry itself, reflected in the accommodation, meal services, entertainment, other current services, and
- the economic activity (agriculture) carried on by the owner of the agritourist guest-house, reflected in the production and primary processing of food in household products and their marketing directly to tourists or through other commercial networks.

The adjacent practicing of agrotourism by peasants in rural areas leads to the development of agricultural products, primarily through the capitalization of their own agricultural products and also through the revenues from accommodation, part of which is used for investments and modernization.

Therefore, the agrotourism directly contributes to the support of the farmers and to the development of the respective area itself.

Moreover, as pointed out at the meeting of the European leaders of the European Associations of Rural Tourism, held in Abtwil, Switzerland, on June 1, 2009, even the crisis in the recent years has negatively affected only the business tourism (city tourism) and generated benefits for the tourism and agrotourism guest-houses in Europe.

Thus, in Austria, Farm Holidays (holidays on the farm) have even more reservations than before the onset of the economic crisis. In France, the situation is similar, a feature

being the fact that people are no longer going very far from home. In England, there was an increase in the stays duration, but with a slightly lower frequency, and in Switzerland, although the stays became shorter, holidays on the farm are more and more required [3].

In Romania, in the recent years, the evolution of the agrotourism development is positive, as shown by the further analysis of this phenomenon, carried on based upon the 2004-2009 timeframe.

The evolution of the agrotourism during the period 2004-2009 will be analyzed based on indicators reflecting the tourist accommodation capacity (*the number of tourists reception structures with functions of tourist accommodation, the capacity of the existing accommodation in operation, the index of the net capacity in operation*) and indicators concerning the tourist activity (*number of arrivals, overnight stays at reception structures with tourist accommodation functions*), emphasized per tourist destinations, per types of facilities and per comfort categories.

Graphic 2. The number of agrotouristic guest-houses

Source: Statistical Yearbook 2010, National Statistics Institute

In the period under review, *the number of agrotouristic guest-houses* increased by almost 60% (Graphic 2) at the end of 2009, they represented 27.7% of the level of tourist reception structures with functions of tourist accommodation, compared to only 22.9% of total, during the year 2004.

The existing tourist accommodation capacity of the agritourist guest-houses is characterized by an upward trend different between 2004 -2009, the percentage increase from year to year being shown in Table 1.

Table 1. Increase percentage of existing tourist accommodation capacity agrotouristic

Anul	2005/ 2004	2006/ 2005	2007 /2006	2008/ 2007	2009/ 2008
%	19,0	30,5	6,2	9,4	17,0

Source: Own calculations based on the data from the Statistical Yearbook 2010, National Statistics Institute

Between 2004 and 2009, the tourist accommodation capacity in operation of the agrotourist guest-houses had an upward trend from 2.132 thousand accommodations-days (3.95% of the total) to 4.735 thousand accommodations-days in 2009 (7.75% of the total tourist accommodation capacity in operation of the tourist reception structures). The accommodation capacity in operation of the agrotourist guest-houses during 2009, per categories of comfort, is shown in Figure 1.

Figure 1. The accommodation capacity in operation of the agrotourist guest-houses, on the category of comfort 2009

Source: Statistical Yearbook 2010, National Statistics Institute

Regarding the index of net use of the tourist accommodation capacity in operation, variations have been noted from year to year,

during the period under review, both for the total of the the reception structures and for the accommodations in the agrotourist guest-houses, the highest values being recorded during the years 2007 and 2008 (Table 2).

Table 2. The index of net use of the tourist accommodation capacity in operation

Year	Total (%)	Agrotourist guest-houses (%)
2004	34,3	15,0
2005	33,4	14,5
2006	33,6	14,4
2007	36,0	16,3
2008	35,0	18,4
2009	28,4	14,2

Source: Statistical Yearbook 2010, National Statistics Institute

The Romanian tourist arrivals recorded in agrotourist guest-houses during the period 2004-2009 showed, until the year 2008, a significant increase, but, during the year 2009, the number of arrivals fell by 9.2 percentage points compared to the year 2008. The same trend was noticed in the case of foreign tourists (growth during the first four years of the analysis), their share within the total arrivals arrivals being, however, much lower than that of the Romanian tourists (Graphic 3).

Graphic 3. Arrivals of tourists in the agro-touristic boarding houses

Source: Statistical Yearbook 2010, National Statistics Institute

The overnight stays registered in tourist reception structures had an upward trend during 2004-2008, the total increase reaching +12.3 percentage points.

That changed in 2009, when the overnight stays registered in tourist reception structures decreased by 16.4% compared to those during the year 2008. In 2009, the Romanian tourists' overnight stays in tourist reception structures with accommodation functions accounted for 84.6% of the total overnight stays, while the overnight stays of foreign tourists accounted for 15.4%.

Concerning the agrotourist guest-houses, the growth trend of the overnight stays was more pronounced in the period under review, so that the total was + 109.7% during the year 2008 compared to the year 2004 (Graphic 4).

Graphic 4 Over night stays in the agro-touristic boarding houses

Source: Statistical Yearbook 2010, National Statistics Institute

The Romanian tourists' overnight stays at agritourist guest-houses recorded during the year 2008, compared to the year 2004, saw an increase of + 148.2 percentage points, compared to only + 25.6 percentage points for the foreign tourists who still showed their preference for high comfort hotels.

3. The role of the agrotourism in the rural development

The two European Conferences of Rural Development, which took place in Cork (1996) [4] and, respectively, in Salzburg (2003) [5], marked the need for a new beginning for policy on the rural development through which the rural areas should become more attractive living and working spaces and should to promote sustainable development worldwide.

The basic principles of the rural development policies aim at: the preservation of a viable rural environment; the protection of the diversity of the European rural environment; the increase the agricultural farms competitiveness (a *key objective*); the rural development policies should apply in all rural areas in the extended EU; the rural development policies are designed to meet the needs of the whole rural society; the rural development policy should be promoted through the partnership between the public, private organizations and the civil society, in accordance with the principles of subsidiarity; greater responsibility for partnership programs and a significant simplification of the EU policy on rural development [6].

For, in the rural areas, only the agriculture itself cannot ensure their proper development, the agrotourism becomes an effective means of achieving that objective.

The agrotourism makes a significant contribution to the development of the rural areas (Hall et al., 2003), for:

- it generates income and jobs;
- it increases the awariness of the value of an area, such as its landscape, nature and culture, as well as their economic potential;
- it increases the diversity of the economic activities;
- it enables exchanges between rural and urban areas;
- improving infrastructure may also provide opportunities for other economic developments.

4. Conclusions

The rural areas account for more than 80% of the territory of the European Union where the fourth of its population live.

Hence, the involvement of the decision makers at community, regional and local levels in the development of these areas.

The agrotourism is a regenerating factor for the rural economies and an element of preservation of the rural environment.

People's need to escape from the urban space toward rural areas which increasingly satisfy the tourists' interest in health, safety, recreation issues, on the one hand, and the haste with which some entrepreneurs wish immediate gains as large as possible, on the other hand, lead to imbalances in rural areas.

However, the agrotourism, which is a chance for the rural life, must use today natural resources, and not only natural resources, without prejudicing to the options of the future generations. And for that we should always remember the words of Lester Brown: **"we have not inherited the earth from our parents, we borrow it from our children"**.

Influence Factors on the Value of Reliability Estimators in Marketing Research

Ursachi George Marian
Ursachi (Horodnic) Ioana Alexandra
"Alexandru Ioan Cuza" University of Iași
ursachi83@yahoo.com
ursachi_ioana_alexandra@yahoo.com

Abstract

This paper is a literature review, with a conclusion that leaves open many doors for future research. In the first part are reviewed a series of qualitative and quantitative research characteristics. The second part explains briefly the reliability and validity of instruments used in qualitative and quantitative marketing research. The third part of the paper review a series of articles on the estimators of reliability, on their power, on their strengths and weaknesses.

The conclusions of the research paper urges to research on the factors that influence the values of reliability estimators to facilitate researchers' access to more powerful and more accurate instruments. A good control over the instruments will allow researchers to overcome cultural barriers or other barriers and to achieve wider and richer results.

Key words: reliability, validity, reliability estimators, Cronbach's Alpha.

J.E.L. classification: M310, C130.

1. Why influence factors?

Analysis of factors influencing the values of reliability estimators is not new, but, with few exceptions, research so far have focused primarily on internal factors, on the construction of the instrument, seeking to determine the cause between the levels of certain factors and the reliability coefficients value. If he master and know these factors that influence reliability, a researcher can choose, depending on the environmental characteristics that he investigates, the instrument that fits best in that environment,

having reliability estimators values located at the highest level.

2. Quantitative research vs. qualitative research

To understand better the differences and possible contraposition of the two types of research is useful and even necessary a characteristics description of the main elements of each and how reliability and validity are assured in these types of research. Before the reliability and validity analysis in quantitative and qualitative research is needed at least a brief description of the two concepts.

The *reliability* of an instrument is given by the consistency to measure a phenomenon. More precisely, the reliability requires that for more measurements of the same phenomenon the instrument to show the same results. This does not imply, however, that the result is correct.

Validity on the other hand involves the measurement accuracy, that an instrument is really measuring what it says it is measuring. For example, a scale that will show each time the value of 9 kg for an object weighing 10 kg is reliable, but is not valid. If the value indicated is 10 kg this instrument will be valid.

An valid instrument is also reliable but a reliable one is not necessarily valid. Validity is more difficult to obtain and to prove than reliability.

2.1. Quantitative research

Quantitative research involves the use of numerical methods, statistical and mathematical relationships, which to explain the existence, frequency, power or other

characteristics of the phenomena. Typically, quantitative researchers, backed by the scientific paradigm, lead us to a world view as it consists of observable and measurable facts, but working with issues of the assumption that social facts have an objective reality and the relationships between these variables may be identified and measured [1]. Measurement involves assigning numbers to material objects, in accord with a set of rules.

A quantitative researcher attempts to fragment and to define the measurable phenomena in common categories that can be extended to all subjects in similar situations. In this attempt the researcher is using standardized measures so that people's varied experiences and perspectives to fit a limited number of predetermined response categories [1].

Quantitative methods are used in research since the early nineteenth century. Florence Nightingale was among the pioneers of this type of research. Concerned by how much the results of such research may lead to a correct conclusion, statisticians have developed, with mathematical foundations, methods for estimating the accuracy and rigor of quantitative research measurements [2].

2.1.1. Reliability in quantitative research

Normally any research instrument should provide the same information if used by different individuals or at different time intervals. Internal consistency is the relationship between all the results obtained from a single test or investigation [2].

Kirk and Miller have identified three types of reliability for quantitative research. The first type refers to the degree to which a measurement repeatedly made, reveals the same result. The second one is related to the stability of measurement over time, and the third one is related to the similarity of measurement within a period of time.

One of the statistical methods for measuring reliability is the split-half test, which involves randomly dividing all responses to a question in two equal sets, aggregation of scores in the two sets and calculating the correlation between the two sets. A more sophisticated and complex method is Cronbach's alpha test, which involves the creation of all possible equal

sets and calculating the average correlation between all. For most research is recommended reliability between 0.8 and 0.9 [3].

Reliability estimation methods for measuring instruments also have some limitations. For example calculating the reliability with test-retest method may be subject to error because the respondents had been tested previously. Moreover, events that have occurred between the two times of administration can influence the development of different responses and contribute to an incorrect external validity [2].

2.1.2. Validity in quantitative research

Validity describes whether an instrument truly measures what it proposes to measure. There are two main types of validity: internal and external.

External validity refers to the ability of applying the study results with confidence on other people and situations and it ensures that the conditions under which the study was conducted are representative for the situation and time to which the results apply [2]. Extracted sample must be representative for the population and the variables must be relevant for study.

Internal validity is examined from three approaches: content validity, criteria validity and construct validity.

Content validity is the lowest level of validity and addresses to the relevance and representativeness of items. It is very important to measure this type of validity if the study is designed to determine knowledge of respondents in a particular area or to measure personal attributes such as attitudes. This type of validity may be acquired through a pilot study with a similar sample (from certain points of view) at what it meant to be studied. Where available, such validity can be supported by documentation and literature.

Criterion validity is the most powerful form of the three validity approaches and is determined when the instrument can be compared with other validated measurements of the same phenomenon. Where they do not exist, this type of validity is not achievable.

Construct validity involves demonstrating the relationship between the studied concept and the construct or the relevant theory.

There are several ways to demonstrate the validity of a construct, among which factor analysis. The factor analysis uses a number of statistical methods to determine the characteristics that share a link. The factor analysis is particularly useful for studying the relationship between a large number of variables, identifying clusters of variables that are closely related [2].

2.2. Qualitative research

Qualitative research uses exploratory methods to produce data and not to measure or quantify them [2]. Qualitative research uses naturalistic methods which seek to understand phenomena in specific contexts that they occur, and are defined, broadly, as any type of research that produces new information from the real world, where they naturally happens, without the involvement of quantitative or statistical methods. Unlike quantitative researchers, which seek causal determination, prediction and generalization of results, qualitative researchers seek illumination, understanding, and extrapolation to similar situations [1].

Just as with quantitative research, questions arise here about the rigor, accuracy and usefulness of results. In an attempt to use methods similar to those used by quantitative researchers, qualitative researchers have faced, as expected, a number of obstacles, which led them to develop a number of techniques and methods specific to qualitative research, with which to determine accuracy, accuracy and usefulness of results.

2.2.1. Reliability in qualitative research

Reliability in qualitative research can be regarded as a trust in the procedure used and in data generated. It deals with the extent to which a measurement results of a study are repeatable in different situations [4]. You must confirm the results by testing or resumption of them in different situations. Detailed notes during the study and other data necessary or useful in decisions helps assessment of research and its confidence.

Other methods for increasing reliability include ensuring the accuracy of the transcript and record. But not only audio registration and the transcripts are important, but non-verbal aspects of communication that

can be omitted in the transcript. For example, even when looking at verbal communication, are very important not only words but also the length or frequency of breaks.

Strong commitment in analyzing data, creating strong links between data and researcher's interpretations, using textual expressions of participants, may increase the reliability of a qualitative study. But it must be ensured that such processes should be used in proportion to their occurrence in the study, not to create errors.

2.2.2. Validity in qualitative research

Validity is understood in terms of how well the research instrument succeed to measure the phenomenon analyzed. A possible and likely difficulty in gaining validity in qualitative research is given by the bias caused by the researcher, bias that may arise from selection and recording of data or their interpretation, interpretation based on personal experiences and perspectives.

Where researchers are involved in or familiar with the subject studied, they may try to be non-reactive and to have a distancing from the subject to allow an objective analysis. Although it is difficult, researchers must suspend experience, judgments and beliefs and provide reliable and valid result [5].

Another method may include validation by respondents. This procedure involves sharing interpretations with respondents who will validate or not these interpretations and provide valuable feedback. But it is risky because some respondents may incorrectly validate the interpretations in response to support the study or the researcher.

A widely used and very robust method of validation is the triangulation. This involves applying two or more methods, theories, sources, converging eventually (and ideally) to the same results. There are used comparison, cross analysis and cross checks for research validation.

2.3. Quantitative vs. qualitative

As can be seen in the table above, both methods of research are needed in a broader research project, each with advantages and disadvantages and each matching a particular

stage of an investigation. The problem that remains to be analyzed refers to the ways of testing or estimating reliability (internal consistency) and validity of research in question. These issues are what we deal with below.

Carefully analyzing the two research methods, qualitative and quantitative we can see that in the center should not sit a "vs." but rather a "+" because they complement rather than contradict. It is true that differs much and that the followers of any of them will always find arguments to prove the supremacy of anyone of them, but be aware that they can only exist together. If a researcher knows exactly what is to quantitatively analyze, he knows that because these factors have been found in previous qualitative research. On the other hand a qualitative research results will be truly validated only by means of quantitative studies to strengthen its findings.

True is that it is very difficult to provide a high degree of reliability and especially of validity in qualitative research, but the fact remains that without this research, quantitative research would not have a starting point and would have nothing to test.

I believe that for a better description of reality it takes a succession of research such as qualitative-quantitative-qualitative-quantitative ..., each one improving and refining previous findings.

3. The current state of knowledge in the field

Research of any type is performed using instruments. For these tools to provide useful information they need to simultaneously fulfill two conditions: must be reliable and valid. Reliability is the instrument quality to measure the same readings for repeating measurements. Validity is the property of the instrument to measure what is really meant to be measured with its aid. Over the time they developed several methods of measuring or estimating the level of reliability and validity of various instruments used in research to ensure a greater fidelity and resemblance of the results collected to the reality.

Providing a high level on the value of reliability and validity estimators is one of the most important aspects in implementation

and use of a research tool. From this perspective, the discovery of the factors that may affect the value of reliability estimators and may influence the direction and intensity of these estimators is very useful to any researcher. Depending on the environment in which he need to conduct the research, the researcher can use the tool which gives the highest level of trust, or he can use certain factors to increase the reliability of the tool (as in the case of internal influence factors they use more items to increase the reliability estimator for that instrument).

3.1. Types of reliability

Reliability is linked to the quality of measurements and has the usual meaning of consistency or repeatability of measurements. Reliability can not be accurately calculated but only estimated. For this reason, over the years, they have emerged several types of reliability, each with a variety of estimating the confidence level of this type. There are four major types of reliability estimators, each estimating confidence in different ways.

- Inter-Rater or Inter-Observer reliability
- Used to describe the extent to which different observers give similar estimates of the same phenomenon;
- Test-retest reliability
- Used to show consistency of measurement in two different moments of time;
- Parallel test reliability
- Used to show consistency of the results of two tests constructed in the same manner and in the same area;
- Internal consistency
- Used to show consistency of results across items that build a test.

4. Evolution and directions

Introduced for the first time in 1937 by Kuder and Richardson, for dichotomous scale and generalized in 1951 by Cronbach, estimator Cronbach's Alpha was and is one of the most used estimators. Lately, however, researchers become increasingly skeptical about the estimation power of this indicator. This skepticism is mostly based on a growing number of studies that prove their relevance and correspondence with reality, but get a

low enough value on reliability estimators for the instruments they use.

As can be seen in the literature, Cronbach's Alpha is questioned by many years, how to interpret the results and its extensive use to estimate the reliability of a research tool are the issue of long and controversial debates.

If at the beginning there were considered reliable tools that score a minimum of 0.70, a number of authors like Bernard in 1994 come to validate studies with the value of Alpha below 0.70. Others such as Iacobucci and Duhachek (2001) [6] are more cautious in interpreting the results and suggest us to take into account the probability of estimator alpha and to consider his value as part of its range of confidence, not as a fixed value.

Thus, if the range falls too low, the tool may not have a high degree of reliability, even if, for example, its estimator value is above 0.70. In the opposite case, even if Alpha's value is below 0.70, its confidence interval can pass this border, so Alpha might be in that area and instrument might be valid, case that would explain demonstrations like the one made by Bernardi (1994) [7].

A number of other authors such as Christmann and Van Aelst (2005) [8] attempts to improve the power of Cronbach's Alpha estimator by eliminating some sensitivity toward the disturbance (outlier in this case). These changes create a more accurate estimator that will estimate the reliability obtained from the majority of the data, eliminating data from other sources.

Others such as Tarkkonen, Puntanen and Vehkalahti (2006) [9] go further, building a more powerful estimator with a wider coverage area, for which Cronbach's Alpha is just a particular one-dimensional case. The estimation power of this new estimator is much higher, because it exceeds the particularity problems that Cronbach's Alpha has and has to fulfill.

In recent years many authors focused on raising the value of Alpha estimator by manipulating internal factors such as number of items, number of constructs, the nature of the scale (formative or reflective) etc. Only a few researchers direct their attention to the influence manifested by a series of external factors on the level of Cronbach's Alpha value estimator. Among them is worth mentioning Montag (2008) [10], which made

a comprehensive study on the influence of speed of completing a questionnaire on the estimator's value. The results show an insignificant influence of this factor on the value of the indicator, but it is a step towards for consideration of external factors of the instrument as being possible factors influencing the value of the estimators.

5. Conclusion

From the sections above can be easily understood, on one hand, how important instruments reliability and validity estimators are for any kind of research, and on the other hand can be seen how controversial are these techniques and methods of estimation for these qualities.

For this reason I think it is very necessary a much better control of these estimators, of what it can influence them, and a better adjustment of them to the environment. If we will know and manipulate these factors that influence the properties of research instruments we will reach a higher research accuracy and the ability to overcome many obstacles that some researchers confront with.

Motivation in Academic Research as an Important Factor in Increasing International Visibility

Ursachi (Horodnic) Ioana Alexandra
Ursachi George Marian
"Alexandru Ioan Cuza" University of Iași
ursachi_ioana_alexandra@yahoo.com
ursachi83@yahoo.com

Abstract

This paper aims to present the main factors that influence motivation in academic research: extrinsic/ intrinsic factors, motivator/ demotivator factors, personal/ interpersonal/ social factors, individual/ collective factors. Also brought into the discussion and the main theories related to motivation in academic research: self efficacy, self-concept and self-determination theory. As a conclusion it is emphasized the link between motivation and productivity and the need to increase the motivation in order to improve a country's international visibility.

Key words: motivation, self efficacy, Self Determination Theory, intrinsic/extrinsic factors, academic productivity.

J.E.L. classification: J21, J23, M30.

1. Introduction

The performance of academic employees who have a dual role as both teachers and researchers, determines the quality of educational act experienced by the students.

Most universities have a mission to provide students a quality education act. This mission can be accomplished only through teachers; therefore, their motivation is crucial. In addition, research has an important role. First, keep alive teacher interest on his topics of interest and secondly, help achieve a positive image of the institution they work for.

Authors such as Rowley believes that teachers that are well motivated publish a lot, and this leads to their international recognition and, hence the recognition of

university which they belong. This has a positive impact in terms of several aspects: valuable students are attracted, funds for research are attracted and consulting contracts are signed. For this reason, the motivation is considered the key to success in increasing the quality of higher education [1].

From this perspective, identifying factors that increase the motivation of university teachers is useful both in local level, to universities leadership and in the national level, for those in ministry that can sustain a national strategy to increase the country's international visibility.

2. Motivation models

Motivation, initially studied by researchers in psychology, is one factor which has sparked the interest of persons from various fields. Marketers turn to studies motivation in several circumstances: when they want to anticipate consumer behavior, when develop or promote a product, when they want to establish strategies for a product or a company etc.

Motivation is a force that makes us constantly move, act or do things [2]. The following lines present the most important models of motivation. Currently there are four well-known models of motivation [1]:

- *The rational-economic model (e.g. Taylor, 1947)*

This model assumes that people are motivated primarily by economic interests and act in such a way as to maximize financial and material gains. Another premise of this model is that people are passive and not willing to make more effort and take more responsibility, being interested only in activities that bring benefits.

Another model that is based on the same assumption, that people are passive is "mini-max" motivation model. Under this model, people want to get maximum benefits with minimum effort. The model not suggests that people do not get the maximum performance because wanting to do nothing or because they are lazy, but because they assess the benefits and costs of involving in a given activity [3].

- *The social model (e.g. Mayo, 1975)*

Unlike its predecessor, the social model assumes that people are motivated primarily by social needs, such as: the need for friendship and acceptance, the need for identity formed through relationships with others, etc. According to this model, people respond better to the group pressure than to the managerial pressures or incentives. People respond to management requirements when they overlap with their needs for affiliation, acceptance and identity.

- *The self - achievement model (e.g. Maslow, 1970)*

The self - achievement model was first developed by Maslow. He proposed a pyramid of needs, where the physiological needs are on the bottom of pyramid and the self-realization needs are at the top. The pyramid has five levels, the last step, the self-fulfillment can be achieved only if the needs of the four steps below have been fulfill. Under this model people like autonomy, independence and skill development for themselves. There is no conflict between self-realization and organizational performance, and people are happy to integrate their objectives with those of the organization where they work.

- *The complex model (e.g. Schein, 1980)*

Schein apud. Rowley criticize the three models presented above due to their tendency to universality and generality. According with this model, the human being is complex, with needs and different motivations depending on the circumstances, life experience, expectations and age. Thus, people are motivated to work when they believe they get what they want from their job. Included are: safety needs, pleasure to do challenging work, the ability to set and meet goals etc. Therefore, managers should seek to identify these needs and to adapt the motivation strategies based on expectations of each employee.

These theories are a relatively simplistic view of motivation. As several studies have been conducted it was found that this concept is very complex and difficult to measure due to the existence of links between variables and latent variables. In addition, was developed by a breakdown of the factors that influence the motivation in *intrinsic factors* and *extrinsic factors*. These factors are set up according to the analyzed topic. Next I will present the most important factors influencing *academic motivation*.

3. Motivation and self efficacy

Authors such as Scheel and Gonzalez have identified a link between academic motivation and self-efficacy. Students who have confidence in their abilities to perform tasks in school tend to be more motivated than those who do not believe in their abilities. The study also revealed a positive correlation between academic motivation and the school counseling [4].

The same relation, between academic motivation and self-efficacy is analyzed by Bailey in a study with a teachers sample. The results of this study show that doctoral graduates have a higher level of self-efficacy for doing research. Also, there are no gender differences regarding motivation to research and level of self-efficacy. In addition there is a direct link between productivity, motivation and self-efficacy [5].

Authors such as Bong and Clark link the motivation for academic research, alongside the concept of "self-efficacy" with the "self concept" term. The study insist on the differentiation of this two concepts: the self-concept is a complex construct that incorporates both affective and cognitive judgments about themselves, influenced mainly by social comparison, while self-efficacy is mostly judgments about the own cognitive capabilities [6]. The self-concept is an important predictor in education, correlated with various educational items such as: academic effort, educational aspirations and academic motivation [7].

Other authors have linked the concept of "motivation" with "achievement theory", namely, the distinction between achieving success and avoiding failure [8].

Other studies that analyze the students behavior to study/ research linking motivation with goals achievement. The behavior is explained either by achievement objectives to demonstrate/ develop skills, or by avoiding them to demonstrate the lack of ability [9]. Avoidance goals are labeled as "academic alienation" and are defined as attempts to allocate as little work and effort is possible to fulfill a requirement [10].

4. Motivation and Self Determination Theory

Self Determination Theory (SDT) is recognized as a fundamental element of motivation [11]. This theory is useful in determining the fluctuations in the strategies, performance and students' persistence. Researchers who developed the theory initially focused on *quality of motivation*. This is the type of motivation underlying learning behavior [12]. Thus, it was explored whether students are intrinsically or extrinsically motivated. *Intrinsic motivation* refers to engaging in an activity only for the activity itself. *Extrinsic motivation* refers to engaging in an activity to get a reward separable from the activity itself [8], [12], [13]. In SDT, intrinsic goals such as helping the community, health, personal development, affiliation are different by the extrinsic goals such as fame, financial success and physical appearance. Subsequent studies have led to differentiate the "goal content" concept (intrinsic vs. extrinsic) from the "goal motive" concept (autonomous vs. controlled). For example, a student can work after hours to get money (extrinsic goal content) because he feel pressured by parents (controlled motive), or because he wants money for college (autonomous motive) [12]. Another factor considered important in SDT is the amotivation (lack of motivation) which refers to the absence of a link between action and reward. People that have a lack of motivation don't have a specific behavior in achieving goals and they are acting in a systematic way [14].

Researchers that have investigated SDT also studied the environmental effects (autonomous/ supportive vs. controlled) on learning behavior. It was identified that students work better with autonomous factors

than with controlled factors and the autonomous/ supportive environment is associated with different benefits [12].

Results of the study conducted by Scheel and Gonzalez support the theory of "self-determination": students who perceive school activities as relevant to their future are generally more motivated. Also, students are rather self-motivated than external motivated (by the controlled factors) [4].

Initially, intrinsic and extrinsic motivations were seen as being antagonistic. Intrinsic motivation reflects the self-determination and extrinsic motivation reflects a lack of self-determination. Later researches showed that extrinsic motivation is not necessarily controlled, distinguishing between several types of extrinsic motivation based on the degree of autonomy or self-determination, given the extent to which people have been successful in internalizing factors that were initially external controlled. This process is called *internalization* and can operate with more or less success. Types of extrinsic motivation that make up this process are: external regulation, introjected regulation, identification and internalization [12]. Authors as Fairchild et. al. called the last type of external motivation as integrated motivation, concept equivalent with the internalization [15]. They placed the four types of extrinsic motivation into a motivational flow between lack of motivation and intrinsic motivation.

External regulation is the form of external motivation that had the lowest level of autonomy. In this case the behavior is explained as a result of external factors such as payment, penalty or deadline, the reason for doing the work is not internalized at all. For example, a student studying in the first place because it would be reward by his parents is externally regulated .

In *introjected regulation*, the second type of external motivation, people engage in an activity to comply with internal pressures often based on self-actualization or to avoid guilt or shame. An example for introjected regulation is a student who learns before play football in order to avoid guilt.

Identification refers to the process in which one person identified herself with an activity and accepts that activity regulation as something personal. An example for identification is a student who learns

statistics because he realizes the importance of statistics in its objectives to achieve empirical psychology studies.

Internalization is the central process of socialization and is defined in SDT as the need for competence, autonomy and links/relationships with others people. This type of extrinsic motivation is very similar with intrinsic motivation, because the competence and autonomy plays an important role, but for internalization the links with other people have also an important role. For example, in order that students to internalize the norms, standards and regulations from a university, they should be presented in a manner that facilitates their needs for autonomy, competence, and relationship/ connection with other people [12].

A different approach we find to authors such as Turner who analyzed the motivation for research according to three levels: personal, inter-personal and community [16].

5. Factors affecting motivation in academic research

Authors such as Dramanics examine the motivation for academic research from two perspectives, both for teachers and administrators from university. Motivational factors analyzed: the assessment of work done, good working conditions, pay, assistance in case of personal problems, involvement in decision making, job security, loyalty to employees, free choice of subjects to teach, promote and professional development and teaching field. The results revealed that managers believe that teachers are motivated primarily by the appreciation of work, while teachers responded that the most important criterion is salary, followed by good working conditions [17].

Mahagaonkar P. examines motivation for academic research by two dimensions: money and prestige. His conclusion is that researchers working with business field want reputation and visibility, making more certificates/ patents. Also, researchers which not cooperate with business field are more motivated by recognition and reputation than by financial benefits [18].

Manley examines the motivation for research around nine motivational factors: intellectual challenge, social status, career

advancement, professional recognition, contributing to the emergence of new knowledge, personal pleasure, material rewards, participation in professional organizations and the development of processes/ products. Applied on a sample of researchers from institutes, the study shows that the most important motivational factors are: intellectual challenge, personal pleasure and financial rewards [19].

Dekker and Fischer analyzed the motivation for academic research based on cultural differences (individualism/collectivism, egalitarianism/ hierarchy). The results showed that people from collectivism contexts are more motivated to prove their capabilities and equality contexts conduct to higher motivation because of freedom of expression [20].

Kiziltepe investigate academic motivation in terms of motivating factors and demotivating factors. His study, conducted on 300 university professors, highlights students as prime motivator factor, followed by career. Students also have been the main factor of demotivation (through lack of interest) [2].

In Romania there are no studies to examine motivation in academic research. In terms of academic research, there is a PHARE study [21] that analyzes the problems of the research system in Romania on various factors. They can be taken into account as a source of demotivation.

6. Motivational factors and productivity in academic research

Authors such as Chen et. al. examines the impact of various motivational factors on productivity in research. The study conducted on economics professors reveals that people strongly motivated by rewards (both intrinsic and extrinsic) publish significantly more articles. Teachers from state faculties are predominantly intrinsically motivated, while teachers from private universities are primarily extrinsically motivated [22].

Affiliation with a state/ private faculty and promotion are strong motivational factors for academic productivity [22]. Also, Long et. al. analyze the link between productivity in research, the affiliations and the school graduated by the researcher. Study results

show that affiliation is a important factor (predictor) of productivity in research both in terms of quantity (number of publications) and in terms of quality (number of citations). Contrary to expectations, the graduated school is not a predictor for research productivity [23].

Tien highlights that motivation to promote has an important impact on research productivity. The author considers variables such as: age, sex, field, Ph. D. status, the country where was prepared as researcher, institution and the personal values system, as predictors for researchers who are motivated by promotion. Respondents are divided into four groups, according with two criteria: (1) importance attributed to promotion shall be located above or below the average of importance attributed from the other respondents and (2) publishing/ not publishing articles or books and access/ not access research funds. The study concludes that universities that attributed high score to promoting importance tend to have younger researchers. Public faculties conduct research with more success than those in the private system. Men publish more books and articles than women. Natural sciences and engineering faculties publish fewer books than the social sciences and humanities faculties, however, ultimately access more funds for research than first ones. Faculties organizing doctoral programs are more productive than other faculties [24]. The same author, in a previous study showed that associated professors and trainers with a great incentive to promote are recording high performance in research, motivation for promotion serving as a significantly predictor for high performance even after controlling some intrinsic or extrinsic factors (rewards, age, sex, rank, the country where was prepared as researcher, affiliation, field) [25].

Some authors like Carayol and Matt focus their analysis on both individual determinants (age, position, field) and collective/ laboratory effect determinants (average age and position of colleagues, the quality of the institution and colleagues, the presence of non-permanent researchers, issues related to team size and financial funds). Conclusion of the study reveals that age and position have no significant influence on productivity, but the size of the laboratory (research group) has a strong and negative correlation:

permanent researchers publish more when they are part of a small laboratory. The same study concluded that local doctoral and post-doctoral students have no influence on research productivity, but foreign post-doctoral students affect positively the productivity [26]. The same authors, in a previous study, say that foreign doctoral and post-doctoral students positively affect the average number of publications conducted by permanent researchers [27].

Brusa et. al. examines the influence of doctoral program in finance on productivity in academic research. The results show that the curriculum does not affect the total number of publications of doctoral students, however, there is a significant relationship between academic program and the number of articles published in ranked journals: doctoral programs that include more math courses in study program recorded several publications in ranked journals [28].

7. Conclusion

Motivation for research is a construct very difficult to be measured, but particularly important for increase a country's international visibility. For this reason, numerous studies have been conducted to discover how you can increase the motivation of university researchers. In the analysis of this complex construct the studies have focused in different angles. The results of these studies have shown that there are many factors that influence motivation, factors that often are correlated, and this makes it even more difficult to measuring them. However, one of the main lines reached from these studies is that motivation is strongly correlated with the academic research productivity (both quantitatively and qualitatively speaking).

Burcă Ana-Maria

Maritime University of Constanța

crisstinadragomir@gmail.com

Abstract

Skilled and experienced crews are essential to the successful operation of today's technologically advanced vessels. The growing shortage of qualified seafarers of today has a dramatic impact for worldwide maritime transport. In order to prevent the disadvantages of seafarers' shortage for economy, a maritime country from Europe, Norway, has a complex approach for identifying best initiatives to attract young people to a seafarer career. This paper presents the reasons for why seafaring is not an attractive career anymore, the public initiatives of the Norwegian government for motivation to join the maritime sector and the private initiatives of Norwegian companies and foundations for solving the shortage problem.

Key words: motivation, seafarer, shortage, Norway, maritime transport

J.E.L. classification.: O15, O18, J24

1. Introduction

The shipping industry is central to the global economy, annually transporting goods – oil and gas, food stuffs and commodities, manufactured products for import and export – that account for approximately 90 percent of world trade. The global fleet of merchant ships is registered in over 150 countries and operated by more than one million crew members of all nationalities.

According to BIMCO and the International Shipping Federation (ISF) 2010 study of the worldwide supply and demand for seafarers, the worldwide supply of seafarers in 2010 was estimated to be

624,000 officers and 747,000 ratings, while the current worldwide demand for seafarers is 637,000 officers and 747,000 ratings. These figures suggest a growing shortage of seafarer. The BIMCO/ISF study highlights that shortages are more acute in specialised sectors such as tankers and offshore support vessels. With regard to certain nationalities, there is an underlying concern about the current and future availability of senior officers. But while there is some evidence of continuing recruitment and retention problems, these are not as severe as envisaged by the last Update produced by BIMCO and ISF in 2005. The data suggests a notable improvement in supply side numbers over the past 5 years, notably in China, India and the Philippines, but also in several OECD countries. The 2010 Update also presents various global supply/demand balance scenarios for the next decade. The results indicate that the industry will most probably face a tightening labour market, with recurrent shortages for officers, particularly as shipping markets recover. Unless measures are taken to ensure a continued rapid growth in qualified seafarer numbers, especially for officers, and/or to reduce wastage from the industry, existing shortages are likely to intensify over the next decade [1].

As European Community Shipowners Association has acknowledged, any government action will be influenced by the need to maintain the competitiveness of European shipping. Balancing strategic and economic needs, particularly in a time of both austerity and geopolitical uncertainty, will be a challenging task. With government spending being ruthlessly cut, any support for training and employing nationals at sea will be difficult to justify.

Even if the governments of European seafarers, like their counterparts in other OECD countries, are able to produce policies that help recruitment and training, decisions already taken by European companies to increase their reliance on non-OECD officers will be difficult to reverse [2].

Norway has the world's 5 largest shipping fleet. In Norway, there are ship finance and ship broker firms that are world leaders. There are also the world's leading companies in insurance, yards and equipment, short sea shipping, tankers, gas transport and car transportation. Norway leads the way in marine research and Europe's largest shipyard group located in Norway. Over 60 000 seafarers from 60 countries are working on Norwegian ships and approximately 20 000 of them are Norwegians [3].

The problem of qualified seafarers' shortage is more complex, as 80-90 percent of maritime accidents can be ascribed to human error.

2. Why seafaring is not an attractive career anymore ?

In order to find the best solutions for motivation to join the maritime sector, the causes that make seafaring unattractive should be carefully considered. Today, enough seafarers are not available to meet the requirements of the industry. Following there are some reasons for which seafaring is not attractive for young generation.

1. Expensive initial training: The course fees demanded by the training institutes are very high for a person to choose shipping as a profession. Further, many maritime institutes are not recognised by the government and legal bodies.

2. Vertical career growth: Some believe that career growth for the persons who take up shipping as their profession is limited. Like in any other profession where one can aspire to become the head of the organisation by competence, here in shipping no such vertical career growth is possible. One may become the Master or Chief Engineer of a Ship or find a job ashore in the maritime domain but vertical growth inside the company is limited or not possible.

3. Limited shore jobs: At some point of life, a seafarer has to take up shore job. But unfortunately, not enough shore jobs are

available for a seafarer. At the most he may get some marine based shore jobs in coastal area.

4. Unstable career: Very few seafarers only can take up shipping as their life time profession, without any career growth. At the end of their life, they realise that no significant achievements were made.

5. Less manpower and more work: Shipping companies, to attract more people in the shipping, tend to pay more salary. This is only an illusion. To pay more the shipping companies reduce the man power in ships. Ultimately the seafarer is made to work more.

6. Not able to cope up with technological developments: The navigational equipments and engine control systems in the ships are mostly electronic. Due to technological advancements, the seafarer has to update his working knowledge of these equipments. If the seafarer is not able to cope up with these developments, he is bound to fail in his profession.

7. Rough seas and sea sickness cause less productivity: As the ship is a three axis moving platform, rough seas cause sea sickness that affects the productivity of the seafarer which is unique in ships.

8. Piracy threats and marine terrorism: Piracy attacks and marine terrorism on the ships are increasing globally. Unlike storm warnings, no one can predict these surprise attacks.

9. Natural calamity: Though storms and rough weather can be predicted, there are increasing instances of ships getting caught in storms and rough weather that result in groundings, collisions and other emergency situations.

10. Multicultural environment issues: The ships are manned by multi cultural crews who have different lifestyles, religions and languages. The seafarer has to adapt himself to live in multicultural environment and a failure to adapt results in lesser productivity of the seafarer.

11. Frequent validations, training needed: To sustain in ships, seafarer has to undergo time bound validation courses in recognised institutes which are time consuming and expensive.

12. Unsafe ships: Ships have definite lifecycle and are not sea worthy beyond that. But shipping companies try their best to

extend their life cycle and sail the ships. The ships become unsafe and the seafarer has to face more marine accidents.

13. Increased suicides in ships: The instances of suicides by the seafarers in ships due to their frustration in work are increasing every year.

14. Salary not adequate: Considering the salary paid in other industries like Information Technology, cost of living and other professional hazards in shipping industry, the salary paid to the seafarers are not adequate.

15. Disturbed family life: A seafarer is not lucky to remain with his family members throughout his career like his shore based professionals.

16. Health: Due to work related stress, non availability of fresh food, lack of recreational facilities and inadequate medical facilities in ships, the health of a seafarer deteriorates faster.

17. Loneliness, boredom: As the seafarer is subjected to "Bigger ships and lesser Manpower" concept of shipping companies, the seafarer till he signs off has to face loneliness and boredom. This also reduces the productivity of the seafarer. To overcome loneliness and boredom, some of the seafarer slowly becomes alcoholics.

18. Faster turnarounds, no breaks in harbour: Due to better cargo unloading facilities available in ports, ships turnaround time has drastically reduced. Practically ships crew don't get any breaks in harbours to refresh themselves.

19. Communication issues: Though English is the universal language, as the ships are manned by multicultural crew, communication problems exist between the crew. In addition communication problems exist between ship and shore authorities. At times, this leads to misunderstandings and cause unwanted incidents.

20. Personal safety: A seafarer has to look after himself and if he is not able to get along with ships crew, his life is not safe.

21. Access to medical facilities: Similarly a seafarer is expected to remain fit and remain seaworthy. Medical facilities are inadequate in ships.

22. Anyone can not be a Seafarer: To become a seafarer, a person has to be psychologically fit in addition to medical or physical fitness. To assess the suitability to

become a seafarer, psychometric tests are conducted at entry level training of seafarers.

23. No recognition in society: A seafarer due to isolation from his family members gets slowly isolated from the society also and has no recognition in the society.

24. A seafarer is visualised by many in the society as high earning member whereas most of the seafarers spend more than they earn. Many seamen do not think of their retirement while they are working onboard vessels until very late in the career. Large number of seamen who do not save for the future and their career at sea came to a halt abruptly without sufficient notice, causing them and their families difficulties in managing day to day living.

The present situation is that the maritime industry is not attractive among young people. Shipping companies and the industry must address challenges in recruiting and retaining skilled officers and crew [4]. It is therefore important to profile maritime industry in a manner that makes it an exciting profession and attractive career alternative for young people.

3. Public initiatives of the Norwegian government for motivation to join the maritime sector

Industrial policies and political framework is very important to the maritime sector. The Norwegian government, a majority coalition dominated by the social democrats, stated in their new governing platform that the maritime strategy stays put. This means a tonnage tax-system and grant arrangements for employment of seafarers in accordance with the state aid guidelines for maritime transportation and a competitive state-supported export financing arrangement in accordance with the OECD regulations.

The focus of the Norwegian government, represented by the Ministry of Trade and Industry is on gaining expertise as a vital element in the development of the maritime industry's competitiveness and for the ability to create wealth.

The goals set out for the Norwegian maritime industry impose demands on education, the development of expertise and recruitment. These are decisive factors in maintaining and developing the ability to generate quality and innovation in the

Norwegian maritime industry. An important measure in meeting the challenges posed by the demand for expertise in maritime industry is the Foundation Norwegian Maritime Expertise (The Expertise Fund). The establishment of the fund in 2003 has resulted in an increase in the number of trainee positions at sea. Foundation Norwegian Maritime Expertise administers a scheme that gives grants in order to have apprentices on board. For the fishing fleet, this support has been limited to training on boats over 24 meters. The scheme has now been expanded to include training also qualified for fishing down to 15 meters. This initiative might encourage more skilled training places for fishing vessels. There will be an important signal to motivate more young people into a skilled marine and maritime education. The fishing vessel owners are asking for skilled labour will contribute to more young people seeking a skilled gateway to the industry. Interaction between marine and maritime sector has promoted new technologies and advanced further development in several important areas. The decision of the Foundation builds up under the cooperation between marine and maritime sector [5].

Regarding maritime education, there is a number of workplaces demand and/or wish to employ persons holding maritime certificates. The fisheries for example compete with the shipping industry for applicants with such qualifications. Access to skilled labour is crucial for the future development in the fisheries sector.

In 2005 the Norwegian maritime industry launched a two-year training programme under the auspices of the Norwegian Ship owner's Association called Maritime Trainee. The participating companies cover a wide segment of the Norwegian maritime environment. Response has been good both due to a large number of maritime companies offering trainee positions and the large number of well qualified applicants.

The Ministry of Education and Research has launched an initiative plan for science subjects with a particular emphasis on recruitment. A national recruitment campaign was implemented in the spring of 2008 with the intention of reaching young people who would not otherwise opt for science subjects,

and in particular female students. The recruitment campaign is co-financed by several parties amongst others: the Ministry of Education and Research, the Ministry of Trade and Industry and the Norwegian businesses and labour organisations.

The initiative plan for 2007/2008 is a follow up of the strategy "A joint effort for science subjects 2006-2009". The Ministry of Education and Research co-operates with Norwegian industry, labour organisations, the Norwegian Association of Local and Regional Authorities and the education sector. Good role models, improved contact with industry and focussed recruiting initiatives can result in an increase in recruitment.

4. Private initiatives of Norwegian companies and foundations for motivation to join the maritime sector

Maritimt Forum of Norway was established as a foundation in 1990. Since then, it has been engaged in bringing the urgent needs of the maritime industry, Norwegian seafarers and offshore into the political limelight. This includes promoting the industry outside Norway as well as fostering co-operation among its several hundred members, national authorities and employee organizations, buyers and sellers. The foundation seeks to strengthen contacts within Norway's maritime cluster, enabling all stakeholders from ship owners to equipment producers to thrive, to enhance their competitiveness and to increase their value. According to the foundation research, there are approximately 97.000 people employed in the maritime sector, Norway's second largest export industry after the petroleum industry. The Maritime Forum is focused on promoting a positive image of the sector among the Norwegian public and to encourage young people, especially those living in coastal districts, to pursue careers in the industry's various branches and in offshore. They constitute the group which will ensure Norway's continued status as a leading maritime nation. The Forum is also working on making a strong case to politicians to take into account the importance of the sector for the national economy and put in place an advantageous

competitive framework - long-term supportive policies and operating conditions that will ensure stability and profitability - on par with competing nations [6].

Maritimt Forum Norway has developed the initiative of establishing an information and recruiting campaign that started in January 2007. The recruitment campaign "Ikke for alle" (Not for everyone) was a three-year campaign that had the objective of attracting young people to take up maritime studies. The project was supported by grants from the Foundation Norwegian Maritime Expertise.

The main target was to reach the youth 15 – 19 year olds and the aim was to inform and getting them to consider a maritime education and life at sea. The campaign was called "Ikke for alle - en utdanning du kommer langt med" which means something like: "Not for all – an education that can take you a long way". A very up to date and functional internet-site has been the centre of the campaign. The initiative has been a success and a negative trend has been broken. After three years Norway experience an increase in applications for a maritime education by 40 percent.

The website Ikkeforalle.no is designed precisely to competent and motivated young people to consider whether a maritime education is something right for them and whether they want a more practical or theoretical training. In cooperation with the maritime training offices in Norway, Maritimt Forum ensures that young people should be aware of what a maritime education and a profession in the industry entails. Shipping companies and training offices work in addition to facilitating apprenticeships for those students who qualify for it.

According to Maritimt Forum research, the number of Norwegian employees in maritime domain is close to 100,000. There are in excess of 95,300 direct employees in the maritime industry in Norway. Number of employees is relatively evenly distributed between the four main groups. Shipping companies have 26 per cent, 27 per cent equipment manufacturers, service providers 28 per cent and 21 per cent of the yards. Number of people working at the shipyards is significantly higher, because the yards have hired labour, for example, from Romania,

Poland, etc., by staffing companies. After a declining trend in employment since the end of the 1990s, there has been a marked increase in employment since 2005, before it goes back down marginally in 2008. Norwegian ship owners employ about 40,000 foreign seamen [7].

The company STX OSV, a major global shipbuilder, constructing offshore and specialized vessels used in the offshore oil and gas exploration & production and oil services industries, has its own initiative to involve actively in recruitment of skilled maritime personnel. The company participates in a student exchange program and through scholarships for students undertaking relevant education and R&D projects. Research related to innovative shipbuilding, new advanced technology and environmental solutions are of particular high interest and their co-funding of a professorship within environment and technology at the University College of Aalesund, exemplifies this [8].

Another maritime company, Ulstein Group, is involved in sustaining research and development initiatives. Ulstein Group is a part of a Norwegian maritime cluster and it considers important to focus on R&D and develop expertise in the maritime domain. Consequently, they have chosen to finance a professorship at Ålesund University College for five years. They also collaborate with Molde University College, drawing on the expertise of its logistics professor in the company's development work. They have also hired in a doctoral research fellow to work on skills development and follow up R&D and innovation projects. Work methods that reduce costs at all levels, while enabling the company to work more efficiently and handle larger volumes, help boost their competitive edge and make them more attractive to the customer [9].

The international work environment and the pressing need for labour contributes to a situation where the maritime industry should expend greater effort in approaching prospective employees with minority backgrounds. The shipping company Høegh is a partner company in the Alarga programme. Alarga is a non-profit special interest organisation that has the objective of creating space in private industry for skilled, young people with two foreign parents of

non-western origin. Active recruitment of young people from minority backgrounds provides an opportunity for shipping companies to reach a larger section of the general public [10].

5. Conclusions

In conclusion, the impact of a shortage in the number of European seafarers would be likely to have serious implications on the operation European fleet and it would also have very serious commercial and strategic implications for the entire European maritime cluster.

In Norway, the maritime industry is among the leading knowledge industries. The maritime industry provides employment to about 100 000 Norwegians and create value over 100 billion. This makes the maritime industry to become the second biggest value creator, for oil and gas.

Norway's initiative to attract young people to a seafarer career can be taken as a model by other European countries that share the same issue, shortage of seafarers, and especially a shortage of well-qualified and competitive seafarers.

Efforts to reverse the decline by governments individually and through the European Union (EU) have had limited success. But in Norway, the existing measures for shipping companies and seafarers (the tonnage tax system and grant arrangements for the employment of seafarers), have had a significant impact not only on the shipping industry itself but on the maritime cluster as a whole. Specialized offshore activities are a central part of the European shipping industry. These activities represent high-tech, high paying jobs and value creation, and face the same global competitive challenges as more traditional shipping. Thus this segment makes a valuable contribution to the maritime cluster and therefore motivation strategies for joining the maritime sector should be focused also in this direction.

Abstract

Given the speed with which we can sail nowadays, the over-loading of road and rail infrastructure and the need to minimize pollution, the seas and oceans gain a crucial importance in the context of globalization.

The shipping industry represents an important component of the global economy, having a major role in the temporal-spatial relationship set between different geographical areas. This industry creates links of value between regions and human groups in order to organize complex categories of commercial and economic activities.

Regarding the specific competition issues of the shipping markets, they are represented by the anti-competitive agreements of the liner trades, known as liner conferences and by the pool agreements which are specific to tramp markets.

Key words: oligopolistic competition, perfect competition, conferences, tramp market, liner market

J.E.L. classification: D41, D43

1. Introduction

The shipping industry has developed in tandem with the global economy, witnessing both ascending and descending slopes of the international trade, gradually turning into a global industry. Nowadays, the shipping industry is represented by an international consolidated community which has modern fleets, advanced communication systems and representative experts, enjoying the fundamental principle of a free trade. Since its appearance, the shipping industry not only

that kept up with developments in global economy, but has also greatly and effectively contributed to the development of global economy.

Due to the diversity and multitude of transported goods, as well as of the large routes which have to be completed, the shipping industry boasts a strong segmentation. Depending on the regularity with which the transport service is required, we have two categories: liner maritime services and tramp maritime services.

2. The liner trades

The liner trades differ radically from other sectors of the shipping industry. Consequently, it cannot be defined on the basis of the individual specialized technology of the vessel, as, for example, tankers. Therefore, it is more appropriate to seek a definition in terms of their operational features, rather than technology used. The main feature which distinguishes liner trades from other sectors is that they are engaged in the provision of scheduled services between specific ports. Scheduled services are those operating at a regular frequency on a particular trade route, according to a published timetable[1].

Essentially, the liner trades may be analyzed in economic terms as being an oligopolistic market structure, in contrast to the competitive markets of the tramp trades. However, it must be emphasized that this does not mean an absence of competition in this type of market. It means that the forms of competition that are present are not plainly observable in the market price. Perfect competition implies that participants compete only on a price basis, but once market structures alter, many other types of

competitive behavior between companies can be observed.

Regarding the demand for liner services, thousands of different cargo types are moved by liner services, with many different goods being carried in the same vessel. As a result of dealing with so many cargoes, liner companies have created a highly complex structure of pricing for classes of commodities. Therefore, every potentially transportable commodity is allocated a product group or class, and charged accordingly.

Regarding the pricing behavior, the striking feature of the rates charged for liner services is their constancy over the time. There is no variation in the rates quoted by the Lloyd's Shipping Economist on the conference routes over the time, in contrast to the single voyage dry bulk rate. The explanation is offered by the economist's concept of administered prices. In certain market situations, the market price does not reflect the daily fluctuations in demand relative to supply. Administered prices are practiced in markets where supply is controlled by the main company or group of companies providing the product, which represents a feature of oligopolistic market structures. Administered prices may exist either if it is expensive to alter them frequently, or if the supply companies cooperate to regulate prices practiced by all companies that operate similar services on a particular route. Both explanations have an element of truth.

Many liner routes are characterized by the presence of a conference which organizes and coordinates economic activities of member lines. These functions may appear to be inconsistent with normal competitive behavior, where rivals act independently in all key decisions. In economic terms, this convenience usually means less competition, higher benefits for liner companies, less innovation and dynamism than in a competitive industry.

In essence, a conference, if it is able to include all liner companies serving a particular trade between named ports, becomes a monopoly supplier of the shipping capacity on that route. It is important to observe that this monopoly exists only over the liner service component of the trade. Liner conference members still face

competition from tramp operators and from air transport, for certain types of cargoes. But the key element in the conference is that members limit the degree of internal competition between themselves. An open conference tries to regulate tariffs and capacity on a particular route, but new members are free to join if they satisfy the rules and obligations of membership.

Regarding the way that conferences set their tariffs, there are two key factors which determine the rate structure, namely the unit value of the commodity and the cargo stowage factor. Companies are entitled to charge by unit value as long as differences in unit value reflect differences in the underlying price elasticity of demand for the commodity.

Conferences have developed certain methods that are designed to limit competitive pressures on the market. There are two sources of competitive pressure, namely one external and one internal. External pressure is brought to bear from air freight competition and tramp shipping. Competition from air freight and tramps is useful to determine the nature of the tariff structure set in the liner trades. It also implies that demand might be price sensitive at the top end, price insensitive in the middle and price sensitive again at the low unit value end of the market, given the competition from air freight and tramps.

In addition to the tariff structure, conferences often provide one of two types of tariff rebate scheme in order to increase shipper loyalty. These are known as the deferred rebate scheme and the exclusive contract scheme. In the case of the deferred rebate scheme, the conferences offer a refund on the published tariff rate to a shipper, if he can show that over the previous six months he has not used a non-conference member's services to move his cargoes. In the case of the exclusive contract scheme, the shipper agrees to move all his cargoes on conference member vessels, in exchange for a lower tariff.

Concerning internal pressure, this type of pressure arises when individual liner companies try to cheat or swindle on the agreement. Conferences try to deal this kind of problems by setting up more complex agreements between members, permitting the central organization to monitor the activities

of individual lines, to ensure that agreements are honored.

In the last thirty years, liner companies have got bigger, operating larger fleets and using larger capacity vessels. The capital needed to support such expansion has led to the appearance of container consortia providing such services jointly and which can be found both inside and outside the conference system. By combining in strategic alliances, liner companies offer shippers fast, regular and reliable sailings. The advent of such agreements, known as global strategic alliances, can be considered as a substantial breakthrough because they are not limited to a single trade lane, but aim to cover every major route. At the same time, these strategic alliances extend their area of influence beyond vessel operations, towards the shared use of terminals, joint equipment management, inland transport and logistics, joint purchasing and procurement[2].

Regarding the position of the European Commission, articles 81 of the Treaty of Rome prohibits anti-competitive agreements which significantly affect trade between its member states. Article 82 prohibits abuse of dominant market positions[3]. Generally, the European Commission accepted that strategic alliances and co-operative arrangements are within the law, because they do not involve price setting or exchanging information on prices.

In conclusion, liner maritime services are more expensive than tramp maritime services, because they have to be provided irrespective of the available quantities of cargoes. Because of the connections with particular charging and discharging ports, liner companies could establish more easily anti-competitive agreements on a particular route or could abuse of a dominant position. The liner trades have been transformed over the past 35 years, as the containerization revolution disseminated throughout the globe. Despite this huge transformation, certain key features still exist, namely the application of price discrimination and the conference system.

3. The tramp trades

The cargoes carried on board tramp vessels are physical cargoes which are themselves being traded, meaning that the tramp vessel service represents only part of the overall supply chain. Cargo can be classified into liquid and dry cargo. A third category is called neo-bulk and comprises non-free-flowing homogeneous bulk commodities. Demand for tramp shipping is closely, but not exclusively, dependent on the underlying physical trade flows. Therefore, there is a close interdependency between the various shipping markets and the underlying markets for the different raw materials, semi-refined products and finished goods.

The tramp trade, due to its features, is very close to the perfect competition model. Tramp services are provided by a large number of owners which operate at major ports around the world, satisfying the demand of a large number of economic operators. The tramp trade forms at the point where the demand and supply are brought together, because there are no fixed destinations, routes or tariffs. The tramp vessels sail over world's seas and oceans, seeking freight transport and mooring at those ports which bring the best transport conditions. All transport conditions are being freely negotiated on freight markets between owner and beneficiary.

Tramp market is an extremely competitive one. Moreover, the trends over the past twenty years have made the market more competitive than it was, especially in the crude oil sector. Perfect competition requires the following four parameters to be fulfilled: atomicity, homogeneity, perfect and complete information and freedom of entry and exit. In such a market, prices would normally move instantaneously to economic equilibrium.

Atomicity represents a feature of a market in which there are a large number of producers and consumers, each so small that their individual actions have no significant impact on others. On tramp market, the producers are the ship owners or operators and the consumers are the charterers. At the beginning of 2006, the world's total merchant fleet comprised about 38 000 vessels of 300 gross tones or more (excluding passenger and special ships, but including

container vessels) [4]. According to Clarkson's, about 26 000 of these vessels were controlled by almost 5 000 companies which means that almost 90% of the companies control less than 10 vessels; on average they each control less than three vessels[5]. It is more difficult to count the number of cargo owners. Anyway, in each transaction involving transportation there are always at least three potential customers. Thus, theoretically, there are several thousand potential customers. Furthermore, in the tramp markets, the producers can also become customers. A shipping company may have entered into a contract of affreightment and for one or more cargoes they may decide to charter in a vessel from the market. Or it may be the result of a shipping company having made contracts for several cargoes, which they intend to transport on one ship.

In some trades (e.g. the iron ore trade), the natural resources are controlled by only a few companies, but the demand side is concentrated too. In 2005, the global maritime trade in iron ore was approximately 670 million tones. Out of this, three companies were responsible for almost three quarters of the volumes annually transported[6]. However, these companies appear to have relatively little control over sea transport, controlling together only about 17% of the chartering. Regarding the demand, the balance of their exports is controlled by their customers who, basically, comprise the global steel industry. Thus, for this cargo the market presents a concentrated supply and although the market as a whole should not be described as atomistic, the sea transport element appears is competitive.

Homogeneity means that goods and services are perfect substitutes and there is no product differentiation. Hypothetically, this is correct in the sense that all vessels of similar types can offer similar services. However, there will most likely be a differentiation in price. For instance, oil exports from the Middle East Gulf to India are shipped in tankers between 10 000 dwt and 320 00 dwt. As freight per unit of cargo declines with increased ship size, the ship owner's total costs increase with size. Furthermore, in most tramp shipping markets, age tends not to be a major factor in determining price, although charterers generally aim for the newest available vessel. This means that an older and

cheaper vessel may earn the same freight rate as a modern vessel. It can be observed that for certain products there is substitutability between different ship types. For example, forest products are shipped in both ro-ro carriers and OHBC's. Further, chemical carriers transport refined oil products as well as chemicals and certain clean petroleum product tankers carry some types of chemicals.

Regarding the perfect and complete information, for the tramp shipping market this is very largely true. For the dry bulk and liquid bulk markets price information is available from a variety of sources to owners and charterers on a continuous basis. Most shipbrokers provide daily and weekly assessments, as well as daily reports regarding individual fixtures concluded. Minute by minute, information is available to clients. Furthermore, the Baltic Exchange publishes daily reports covering over 64 individual routes for tankers, bulk carriers and gas carriers. For more specialized types of vessels, information on prices may be obtained not so easily. However, some shipbrokers operate in specialized shipping segments that monitor and regularly assess freight conditions. This information is not always published, but is often available upon request.

The last parameter that has to be fulfilled is represented by the freedom of entry and exit. The main factor which determines the ease of entry is access to capital to pay for a new or second-hand vessel. Many new ships are purchased with a mortgage, usually for 70% of the initial price, 30% being paid for the shipping company. Many of these investments are made at the top of the shipping business cycle, when freight rates and time charter fixtures are relatively attractive. Exit may be by scrapping the vessel, or for an individual company, selling to another operator. Since there are so many buyers and sellers, only in exceptionally bad market conditions might be a problem with exiting the market.

Specific to the tramp markets are the pooling arrangements which usually involve a number of separate legal contracts designed to give the pool manager the relevant powers to administer and manage the pools on the members' behalf and to provide for the chartering out of the pooled vessels to the

customers of the pool. Generally there are two levels of chartering, e.g. a charter from the relevant owners to the pool manager, and then a sub-charter from the pool manager to the ultimate customer. Many pools offer their customers a range of contract types. The tramp markets also have other horizontal arrangements known as "co-service agreement" and cross-space charter arrangements under which shippers are able to obtain shipping services from two or more operators at the same price and on the same terms.

Abstract

Turkey faced with two important economic crises in the last decade. The faults in Turkish fiscal system have had important shares in these economic crises. The crises have also affected Turkish fiscal system. Moreover, the indirect taxes in a considerable amount are the most important feature of Turkish fiscal system. So, Turkish tax system is often criticized as unjust. It is argued that Turkish economy has overcome the last economic crisis sooner by means of its tax system, because the indirect taxes are more sensitive to conjecture and more elastic than the direct taxes in Turkish economy. In this paper, after the cyclical sensitivity of the taxes in Turkish economy is tested for the period of 1998:01-2010:06, their sensitivity to the crises and their efficiencies as automatic stabilizers are analyzed.

Key words: Turkey, Automatic stabilizer, Output gap, cyclical sensitivity of taxes.

J.E.L. classification: E62, H21, H30, H60

1. Introduction

In the last decade, the fiscal discipline was established successfully in Turkey. On the one hand, the expenditures were tried to be diminished; on the other hand, the structure of the taxes were reestablished to be compatible with this situation.

The Global Economical Crisis 2007-08 affected Turkish economy especially in 2009. But, in contradistinction to the expectations, the economic indicators began to improve. It is argued that the fiscal discipline which was

appeared in Turkish economy had important effects in this improvement.

In addition to the fiscal discipline, the cyclical sensitivity of the taxes in Turkey must to be considered in. The tax elasticity, so the cyclical sensitivity of taxes is important especially in economic crises. If the cyclical sensitivity of taxes is high, the resistance of a country against economic crises will increase. Turkey, especially its fiscal system, put in good performance in the last crisis. The effectiveness of the cyclical sensitivity of taxes must be examined in detail within the frame of this successful performance.

2. Theoretical Framework

The cyclical sensitivity of taxes is examined within the frame of the automatic fiscal stabilizers. When the issue of the automatic stabilizers is taken into consideration, especially progressive income taxes, come to mind at first. In the anti-cyclical budget policy, taxes are only one side of the front.

Automatic fiscal stabilizers are defined as the public revenues and public expenditures which are associated with the economic cycle. The automatic fiscal stabilizers are the fiscal policy factors diminishing output fluctuations without direct government intervention. In this context, as taxes are decreased and public expenditures are increased in economic recessions, some public budget items are used to remove the effective demand fluctuations in economic recovery [1].

According to the main essence of Keynesian model, the effect of the total demand-oriented endogenous shock on output and total current expenditures is diminished by the automatic stabilizers which decrease these effects of the shocks on disposable current income. Personal income and taxes which determine the consumption demand must only be underlined as key components. Automatic stabilizers decrease multipliers as shown in the formula below [2];

$$at/(1-\alpha+\beta) (1-\alpha+at+\beta) \quad (1)$$

α = after-tax income's marginal propensity to consume

t = marginal tax rate

β = a coefficient which shows the crowding out effect of prices and high interest rates on total demand

In addition to the sensitivity of budget for cyclical developments, the size and operational mechanism of the automatic stabilizers also depend on the government size, the economic structure and the nature of economic shocks. In theoretical models, the effect of the automatic stabilizers on government budget is defined implicitly. In practice, the size of the automatic stabilizers is determined by favor of deducing from the cyclical sensitivity of the fiscal variables which are estimated on the base of accessible data [3].

The automatic stabilizers which are considered as taxes have a rule-based advantage because they give reactions to the changes in activities immediately and ensure opposite-direction expectations which can limit more public borrowing over long-run high interest rates[4]. As the automatic fiscal stabilizers support the growth in the first year after the recession, they can also play a role to turn some possible recessions into normal compensate growth period. Fiscal stabilizers prevent sharp economic fluctuations and in this way they can increase long-run economic performance and prevent the changes in the rates of expenditures and taxes which are occurred frequently [5].

When people believe that the change in tax revenues don't change the inter-period budget constraint of the government, the automatic stabilizers partly decrease the uncertainty about future revenues and become effective if they create wealth effect.

Automatic stabilizers will have strong effect if households come across debt or budget constraint. The households having high liquidity constrained cause the tax changes which are dispersed between different brackets. These households and low income injustice help the development of automatic stabilizers' effect [6].

The cyclical sensitivities of taxes as automatic stabilizers are estimated by means of tax elasticity. In a given tax rate, the change in income causes the same direct change in tax revenues. In this way, the elasticity of taxes can be increased. This elasticity's effect decreases the value of multiplier. Thus, if the tax elasticity becomes high level, it means that the taxes have the feature of automatic stabilizer.

There are some differences about the effectiveness of the automatic fiscal stabilizers between countries; because each country has different economic structure and economic system. Moreover, the comparisons between the country groups can be significant. There are also differences between developed and developing countries about the ability of using automatic stabilizers and the successful of getting result from them [7].

3. Model

In this paper, the cyclical sensitivity of the taxes in Turkey is tested for the period of 1998:01-2010:06. Monthly data are used for the given period. After these data are made real, they are adjusted seasonally.

The potential output and output deficit are estimated in the first stage. In spite of different definitions about the potential output, it can be defined briefly as the aggregate growth rate in the long run. The potential output level and output deficit which are to be used while the cyclical components of the tax revenues are estimated in this paper are calculated by means of Hodrick-Prescott Filtration analysis. This method determines the output serial (Y_t) as two components which are growth (Y_t^p) and periodical variable (C_t). In this context, the growth represents the potential output and the periodical variable represents the output deficit.

$$Y_t = Y_t^p + C_t \quad (2)$$

In this method, the difference between the current output and the trend output and also the difference between the trend output and the growth rate of trend output must be minimized together. The aim of the leveling is to make the actual output serial represent in correct. Anyway, trend variable is also based on leveled form.

After the potential output and the output deficit are estimated, the cyclical sensitivity of taxes can be measured. Thus, the taxes are separated to their structural and cyclical components. To find their structural and cyclical components, the point elasticities of the taxes must be estimated [8]. When the methodology of Van den Noord is followed, the cyclical components of the tax revenues are calculated by subtracting the estimated structural components of tax revenues from their actual levels. The structural components, in turn, are calculated from actual tax revenues, adjusted proportionally according to the ratio of potential output to actual output and the assumed built-in elasticities [9]. Thus:

$$b^{**} = b - b^* \quad (3)$$

b^{**} = cyclical component of category of tax
 b^* = structural component of category of tax
 b = actual tax revenue

$$T_i^*/T_i = (Y^*/Y)^\alpha \quad (4)$$

T_i^* = structural component for the i_{th} category of tax
 T_i = actual tax revenue for the i_{th} category of tax
 Y^* = level of potential output
 Y = actual output
 α = elasticity coefficient

To investigate the change in the composition of the tax revenues, the taxes are separated as direct taxes and indirect taxes. Then, the same analyses are also made for the income and gain taxes, the good and service taxes and the foreign trade taxes which are the components of another tax classification. First of all, the point elasticities are estimated for each period. Then, by means of the estimated point elasticities, the structural and cyclical components of direct and indirect taxes are determined.

After that, the direction and intensity of the relationship between the variables is tried to determine by means of the analyses of regression and correlation. The simple linear regression analyses are made to determine any relationship between the tax types and GDP. In the regression, while the tax types are presumed as dependent variables, GDP is presumed as independent variable. In this way, how the changes in GDP affect the tax types is determined. For these analyses, the program of SPSS 16.00 is used. The used regression model can be shown as below:

$$Y_i = \alpha + \beta X_i + \varepsilon \quad (5)$$

Y_i = Tax Category (Dependent variable)

X_i = Gross Domestic Product (Independent Variable)

α = Intersection Term (When $X_i = 0$, it shows the value of Y_i)

β = The Slope of the Line (The ratio of the unit change in X_i to the change Y_i)

ε = Error Term.

After the regression analyses, tax elasticity is estimated for each tax category. By means of the tax elasticities, the cyclical sensitivity of the taxes is tested. In this way, the effectiveness of the taxes as automatic stabilizer is measured. Tax elasticity is estimated by means of the elasticity formula shown below:

$$e = (\partial y / \partial x) * (\bar{x} / \bar{y}) \quad (6)$$

As the elasticity expresses the ratio between the changes in percentages occurred in two variables, the slope is the ratio between the absolute changes occurred in two variables. In the formula above, $(\partial y / \partial x)$ represents the slope. This slope expresses the ratio of the absolute change in dependent variable to the absolute change in independent variable. β coefficient which shows the coefficients in regression represents the slope in model. This ratio shows the first term in the elasticity formula above. The value \bar{x} taken place in the formula is the aggregate of the real GDP serial which is an independent variable. The value \bar{y} represents the aggregate of the tax revenues which are dependent variables. So the formula can be written as below:

$$e = \beta * (\bar{x} / \bar{y}) \quad (7)$$

If the elasticity coefficient is high, the feature of the automatic stabilizers of taxes is

also high. In this paper, the elasticities of total, direct and indirect taxes are estimated and these values are compared to each other.

4. Analyses Results

In this paper, the cyclical sensitivity of the tax revenues in Turkey and their automatic stabilizer feature are tried to test. In this context, the tax revenues of the central administration budget are separated as direct and indirect taxes. And, this classification is used in the analyses. The total taxes, direct taxes and indirect taxes are analyzed respectively. The data which are used in the analyses are gathered together from the statistical databases of Central Bank of The Republic of Turkey [10] and The Republic of Turkey Prime Ministry Undersecretariat of Treasury [11]. Firstly, the development of tax revenues is examined for the given period. Then, total taxes, direct taxes and indirect taxes are analyzed to test their cyclical sensitivity for the period of 1998:01-2010:06.

The actual GDP, potential GDP and output deficit are shown in Graph 1. Actual GDP has deviated from its trend value by years. The size of this deviation is quite high in the base years. As it is seen from Graph 1, the maximum deviation year is 2009 which is the crisis year in Turkey. The value of actual GDP is substantially lower than the trend value of GDP in this year. Thus, it can be said that the output deficit in 2009 reflects the effect of the crisis clearly.

Graph 1. Actual Output, Potential Output and Output Deficit ($\lambda = 14400$)

The structural and cyclical components of the total, direct and indirect tax revenues are shown in Graph 2, Graph 3 and Graph 4, respectively. It is seen that the significant fluctuations were appeared in the cyclical component of the total tax revenues in the crises periods of 2007-09 and 1999-2001. Nevertheless, the fluctuation in 2004 was delivered from the voluntary arrangements. In the structural and cyclical components of the direct tax revenues, a significant deviation was appeared in 1998. The deviations in the years of 2001 and 2007-09 were relatively unimportant.

Graph 2. The Structural and Cyclical Components of The Total Tax Revenues

Graph 3: The Structural and Cyclical Components of The Direct Tax Revenues

Graph 4: The Structural and Cyclical Components of the Indirect Tax Revenues

The cyclical and structural components of indirect tax revenues are shown in Graph 8. The deviations in the structural and cyclical components of indirect tax revenues which were appeared in the years of 2000-01 and 2009 are remarkable. Especially, the negative forms of the tax revenues in 2007 and 2009 show the size of the crisis.

The significant deviations from the trend value of GDP are seen in 1999, 2001 and 2009. The changes in tax revenues also show significant deviations in the crises periods of 1999-2001 and 2008-09. As it is seen from Graph 5, the tax revenues react to the changes in GDP more intensely in Turkey.

Graph 5. Percentage Changes in The GDP and The Total Tax Revenues

To answer the question of how much the development in GDP explain the tax revenues, another twist is taken and correlation and regression analysis made. The results of regression analyses made for the direct and indirect taxes by means of the package program of SPSS 16.00 are shown in Table 1. In addition, the tax elasticities (β)

are calculated by use of the slope coefficients derived from the regression analyses. These elasticities are also shown in Table 2.

Table 1. The Regression Between The Taxes and GDP and Their Elasticities

	Indirect Taxes	Direct Taxes	Total Taxes
Pearson Correlation	0,951	0,920	0,947
R Square	0,904	0,847	0,896
Std. Error of the Estimate	1063864	629450	1467318
F	1389,1	817,6	1275,3
Sig.	0,000	0,000	0,000
Beta	0,951	,920	0,947
Elasticity	2,7	1,27	0,96

The correlation coefficient (R) is calculated to determine the level and direction of the relationship between two variables. If the correlation coefficient is positive ($r > 0$), it means that when the data of variable increases/decreases, the data of the other variable also increases/decreases at the same time. This situation is the evidence of a linear relationship between variables. If the correlation coefficient is negative ($r < 0$), it means that when the data of variable increases/decreases, the data of the other variable decreases/increases. This situation is the evidence of a reverse direction relationship between variables. As the correlation coefficient of the total taxes is calculated as 1,947, this coefficient for the direct taxes and indirect taxes is calculated as 0,920 and 0,951 respectively.

R^2 represents that how much the independent variable determines the dependent variable. As R^2 approaches to (1), the independent variable's determination degree of the dependent variable increases. The relationships between GDP and the direct, indirect and total taxes are statistical significant at the level of one percent, because p is smaller than 0,01 in the regression made. As the determination coefficient (R^2) for the total taxes is calculated as 0,896, this coefficient for the direct taxes and indirect taxes is calculated as 0,847 and 0,904 respectively. In sum, the change in GDP explains the change in the tax revenues at the level of 0,896 and the change in the indirect taxes at the level of 0,904.

Similarly the change in GDP explains the change in direct taxes at the level of 0,847.

As it is mentioned above, β is the slope of the regression analysis. By means of the slopes, the elasticities are calculated. As the elasticity coefficient of the total taxes is calculated as 0,96 ($e=0,96$), this coefficient for the direct taxes and indirect taxes is calculated as 1,27 ($e=1,27$) and 2,7 ($e=2,7$). The elasticity coefficient measures the intensity of the changes in tax revenues when GDP changes. In other words, it is the sensitivity degree of tax revenues to the change in GDP. The change in GDP explains the change in the tax revenues at 96 percent. The elasticity coefficient of the direct taxes is calculated as 1,27. This situation shows that if GDP changes at the level of one percent, the tax revenues change at the level of 1,27 percent. The sign of elasticity coefficient can be negative or positive. If the sign is positive, it means that direct tax revenues change in the same direction with GDP. The elasticity coefficient of the indirect taxes is calculated as 2,7. This situation shows that if GDP changes at the level one percent, indirect tax revenues change at the level of 2,7 percent. In addition, it can be also said the indirect tax revenues change in the same direction with GDP.

5. Conclusion

In this paper, the effectiveness of automatic fiscal stabilizers in Turkey which is a developing country is examined. According to the analyses results, the direct and indirect taxes have been effective as automatic stabilizers in Turkey since 1998. The remarkable result which is reached that contrary to the expectations, the feature of being automatic stabilizer is much more evident in the indirect taxes in Turkey. In short, the indirect taxes are more sensitive to cyclical than the direct taxes in Turkey. There are some factors to cause this situation. First of all, the share of indirect taxes in total taxes is quite high. In other words, Turkish tax system is based on the indirect taxes. Secondly, indirect taxes are rather taken on expenditures. Lastly, when cyclical changes these taxes also change at the same time. In this context, these conditions increase the cyclical sensitivity of the indirect taxes in Turkey.

The Internet of Things: the Electronic Passport

Varese Erica

Department of Commodity Sciences, University of Torino,

varese@econ.unito.it

Buffagni Stefania

Gest-Cooper Soc. Agr. Coop. Consortium,

buffagni.s@gestcooper.it

Abstract

For many people, the Internet of things represents the future of technology. The Internet will constitute the connective tissue which binds reality together, and will be easy to access for people, animals and even objects.

The birth of technologies such as wireless sensors, nanotechnologies and intelligent labels has brought about a turning point in communication methods; both inside the organisation and production processes of many firms, and within the private spheres of individuals.

Taking as a starting point the analysis of a key technology for the Internet of Things, RFID, the purpose of this study is to display the strengths and weaknesses of one of the most highly discussed technological innovations of the last decade; the digital passport.

Key words: internet of things technology, RFID technology, electronic passport.

J.E.L. classification: O 14

1. Introduction

In 2005, the agency ITU - *International Telecommunication Union*, used the term "*Internet of Things - (IOT)*", for the first time, to define the capacity possessed by things, objects and machines to connect autonomously to the internet. In other words, access to the Internet would no longer be limited to personal computers. Rather, any individual or thing would be able to connect at any point in time, and in any location. The key concept behind IOT, now recognised by governments, universities and industry, is the idea that objects, especially those of

everyday use, can be read, recognised, located and controlled via the Internet.

While up until just a few years ago this aspect might have seemed an almost space age concept, this is no longer the case today. In fact, with their capillary distribution, intelligent technologies such as nanotechnologies, intelligent labels and *wireless* sensor networks have permitted *real-time* communication and information exchange, not only between individuals connected to the network, but even everyday objects. In order to achieve this objective, it has been necessary to call upon the many potentialities of the internet, a platform which, since its origin as a small network, has now come to comprise more than a billion users. Internet development over the years has been so great as to ratify the movement from protocol IPv4 to IPv6: these protocols specify the amount of space dedicated to Internet users. The former, IPv4, can generate 4 billion (4×10^9) addresses, which is still insufficient to meet the actual requests on the web. As a result, ICANN (*Internet Corporation for Assigned Names and Numbers*) decided to expand the address assignment possibilities through protocol IPv6, which allows the number of addresses to go up to $3,4 \times 10^{38}$. [1]

In the world of the *Internet of Things*, the Internet constitutes a connecting fabric for all those electronic devices (mobile phones *in primis*, but also cars and household appliances) which "surround" man.

Although initially designed in the industrial field and used for the management of production processes, these applications are now also widely applied in people's private spheres, and inevitably come to condition their way of doing things and daily habits. Practical examples of this can be seen in projects connected with domotics, so-

called "intelligent homes" and household appliances which can be programmed using the internet, as well as all the new opportunities linked with e-commerce and personal security management (such as access control systems). Even the mobile telephone has now become inescapable, an integral part of daily life: From its original form as a "simple" wireless communication instrument, it can now be used for the fast transmission of data, files and images, to receive and send emails via Bluetooth or Wi-Fi technologies, surf the Internet and make payments.

The notion of a world closely connected with technology raises many perplexing questions, however. What will the implications be for the security of data transmitted, the protection of people's privacy and the reliability of information received? New codes, passwords, real time sharing of information, and technologies capable of anticipating our demands; are such things really indispensable for everyday life?

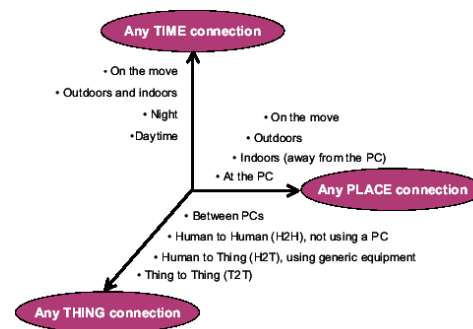

Beginning with an analysis of the *Internet of Things* and a closely connected technology, RFID, the purpose of this study is to analyse the potentialities and criticalities of one recent innovation: the digital passport.

2. The IOT and information technologies: some considerations

As suggested thus far, the *Internet of Things* is destined to signal a new era of communication; one in which people can be connected to any sort of object, as can objects between themselves. We are faced with a "worldwide network of networks", based on standard communication protocols, in which single objects can be interconnected and operate in cooperation with each other.

If personal computers already enabled more precise and faster processing and sharing of data, with the introduction of first the Internet and then mobile networks, many "space and time" barriers have been abolished, enabling the acquisition of an "any-time" and "any-place" connection. [2]

Figure 1. New space and time barriers

Source: International
Telecommunication Union, Geneva, 2005

Communication thus takes place in "3D", i.e. involving the three dimensions of TIME, SPACE and, above all, ALL THINGS and PEOPLE. As can be seen in Fig.1., there are no longer any limitations relating to; physical connection spaces (from the PC in movement, for example through a mobile phone, outdoors, in an office even leaving aside the use of a PC); connection timeframes (it is possible to connect to the web at any time, be it at home, in the office, for short periods of time or for a more extended periods, etc.); and above all the subjects/objects that can enter into communication: people with other people, computers belonging to the same information network, people with objects and even objects with other objects.

These last two points represent the very essence of IOT: a general communication system is in fact capable of transferring information from one "machine" (on its own functioning mode, its own location, the value of a parameter detected) either to another "machine", which can register the datum or activate a series of predefined actions, or to a mobile device (mobile phones, smart-phones or the like), managed directly by a person who will deal with registering and managing the information received. [3]

These communication solutions can have a substantial impact both on the organisational processes of many firms, and on people's private spheres. One therefore comes into increasing contact with electronic consumer devices fitted with integrated microprocessors capable of communicating independently with central supervision systems, increasingly without the

involvement of a human component to control the flux of data.

The aim is to improve and speed up the exchange of information, in that every entity connected to the web possesses their own "identity", and is able to recognise and therefore communicate with other elements on the global network.

In order to give a concrete form to what has been said thus far, an example of technology used in IOT can be seen in *Radio Frequency Identification* (RFID). This system is based on the transmission of data contained inside a *tag* (equipped with a *microchip*) through the modulation of radio waves. Subsequently, these data are converted into digital signals and transmitted to a computer to be shared on the web. [4]

RFID can be considered to be the evolution of mono-dimensional barcodes. Currently, these barcodes are the most widely used solution, since they are more economically advantageously than other types of labels. Nonetheless, recent technological developments (such as new production materials, the implementation of software applications etc.) are contributing to the large-scale use of RFID.

So, to consider the question in greater detail, what exactly are the potentialities of RFID? Firstly, its application versatility: a *tag* can be integrated into a wide range of materials (paper, powders, fabrics, metals, foods, etc.); it can withstand different temperatures and can be designed in dimensions tailored to specific requirements and environmental conditions. Moreover, the memory of the microchip inside the tag can be extended up to many Bytes; depending on the data which it contains. [5]

In this light, any object can be identified and geolocalised. Moreover, by fitting the chip with particular sensors, it is ultimately possible to detect data such as temperature, environmental humidity, brightness, etc. It thereby becomes a fundamental instrument also for monitoring important parameters for the management, for example, of production processes. [6]

As already stated, these automatic identification technologies are already in use in everyday life: the most common examples are the 'telepass' (remote toll payment system), subcutaneous tags for identifying animals, anti-theft systems (used primarily

by large-scale distributors) [7] and, more recently, the electronic passport.

Adopted in Italy from 1 January 2006 through Law n. 43, art. 7-vicies-ter dated 31 March 2005, although this last application has on the one hand introduced undisputed advantages, it has also given rise to considerable perplexity. While one of the advantages of IOT is that it permits rational, high precision management of highly complex communication processes, a lot of attention must still be given to the manner in which such technologies are used. In particular, if the virtual world is able to "trace" the real world, it is necessary to lay down "behavioural codes" which protect individuals' confidentiality, in particular as regards personal, habits and consumer data.

3. The electronic passport

The digital passport, or electronic passport, is a travel document fitted with RFID technology; identical to a paper passport and with the same purpose of identifying travellers. It differs from the latter in that it is fitted with an RFID proximity microprocessor inserted into the first page of the cover. By using radiofrequency functionalities, it is therefore possible to memorise a series of sensitive data so as to immediately identify the passport holder. The purpose is to guarantee greater security in airports, at customs, etc. [8] These necessities have been noted above all following the terrorist attacks which have occurred internationally in the last decade. [9]

Figure 2. Electronic passport

Source: Cards&More.com

The first State to introduce this innovation was Malaysia in 1998, followed by the United States in 2006. In that same year, via a publication in the Official Gazette –

General Series, dated 14/04/2006, the Italian government approved the Ministerial Decree, dated 31/03/2006, "Electronic Passport Regulations". This led to the aforementioned Law of 2005 which stipulated the substitution of the paper passport with the new, electronic version. In the early months of 2009, a modification was then made to this measure, requiring the addition of two digital stamps on the travel document. The new regulations were to be applied from 28 June of that year.

Decree no. 303/13 dated 23 March 2010, "Regulations regarding ordinary passport books" defines the characteristics of these passports in greater detail. In particular, the chip inserted into the passport must be in conformity with directive ISO 14443 (used to define the standard of *contactless smartcards* used in electronic ticketing systems, the identification of people and objects, payment systems, access control systems) and must meet the specifications of the *International Civil Aviation Organization (ICAO)*, with a minimum capacity of 80kb and durability of at least ten years. The ICAO standard has introduced a group of cryptographic protocols to meet the minimum security and privacy requirements for information contained in the chip. It stipulates particular characters, placed on the first page of the travel document, known as MRZ (*Machine Readable Zone*). Without these, it would not be possible to identify the passport holder. [8]

But what data is actually registered inside the microprocessor?

Again in accordance with Decree no. 303/13, the image of the holder's face and their digital prints must be recorded in an intra-operative format. At the time of the request, citizens must therefore place both the index finger of their left hand and that of their right hand on a special optical reader, the purpose of which is to "translate" into electronic language the biometric print, which will subsequently be inserted into the *chip*. This print detection process is to be repeated three times for each finger, for a total of six prints; from these, the highest quality print will then be selected. [10]

Moreover, all the data already present on the paper version must be copied onto the microchip (vital statistics of the owner and passport number), as well as information

codes for the protection and inter-operability of the data [11]. Figure 3 shows an image of an optical reader of digital prints.

Figure 3. Optical reader of digital prints

Source: State Police [10]

It is therefore apparent that the correct management of data contained in the passport constitutes an extremely delicate issue; the greatest fear is that devices fitted with a receiver similar to that of the RFID antenna will be able to intercept the signal transmitted by the *tag*, with a not too remote risk of identity theft. The protection of sensitive data relating to an individual has led the CAO to set out certain security protocols, among the other data [12]. These include:

- *Passive Authentication (PA)*. The sole purpose of passive authentication is to check the veracity of the passport by testing the digital signature contained therein, as issued by the competent authorities. Via a series of codified data (called LDS), the protocol checks that the signature issued by the RFID reader coincides with the one memorised in the document;
- *Basic Access Control (BAC)*. The basic access control protocol avoids the danger of *skimming* (unauthorised reading of the document by equipment able to intercept communication between the *tag* and the antenna) and *eavesdropping* (interception of communication). Because of its importance, this is the first process to be activated upon the connection between *transceiver* and passport. As stated above, the document is fitted with a sequence of characters called MRZ, which are fundamental for reading it. At the beginning of the communication via radio waves, both the *microchip* and the reader receive a copy of "reading keys" from the MRZ. Following this, numerous coded

strings are sent, which are required to check the personal data of the document holder.

- *Chip Authentication* (CA). The purpose of the *chip* authentication is to avert any potential cloning of the *microchip* contained in the electronic passport. Protocol stipulates the insertion, inside the *tag*, of a secret piece of information, which can be read by and transmitted to the reader only;

- *Terminal Authentication* (TA). This form of protocol checks the veracity of the reader, in order to avoid readings by unauthorised equipment. This is activated via an exchange of keys containing coded messages, between the passport and the correct reader. In particular, the latter sends a form of personal digital signature to the *chip*, which will test its authenticity.

It should be noted that, in order to activate each of the protocols described above, an RFID reader is absolutely indispensable for digital passports, as in Figure 4.

Figure 4. Image of an RFID reader for digital

passports

Source: R.M. Capocelli, "The security of Italian electronic passports" [12]

4. Advantages and disadvantages of the RFID technology applied to passports

What are the main advantages to be gained from the introduction of electronic passports?

In primis, the certified and immediate identification of travellers, thanks to the data contained in the *tag* and the biometric components recently added. Moreover, it is of note that particular importance has been accorded to this demand since the tragic events of 11 September 2001. It has in fact become indispensable not only to recognise

individuals, but to be certain both of their identity and their place of origin.

Secondly, the electronic passport can represent a further obstacle for the forgery of travel documents.

Thanks to the countless coding systems for information exchanged between *chips* and antennae, as well as biometric data such as iris scanners and digital prints, forging an electronic passport has become anything but simple. This innovation therefore represents a noteworthy deterrent for clandestine immigration through false or manipulated travel documents. This is also a help for staff at passport controls, in customs offices, for example at the airport. On the one hand, the control procedures are accelerated, in that all you have to do is insert the book into the reader. On the other hand, the risk of not recognising a counterfeit passport from an original one, after a first manual and visual analysis, is drastically reduced.

One aspect to be highlighted, and which has already been mentioned, is the protection and *privacy* of personal data through complex coding keys, with the aim of avoiding identity theft.

Despite the adoption of preventive measures, in the past various points of weakness have nonetheless arisen following the adoption of such passports. In Belgium, the first passports distributed were immediately withdrawn, as a result of their being possible to intercept, and easy to tamper with. Is this still the case? Does identity theft still constitute a well-founded fear?

Many experts maintain that *contactless* reading is the primary criticality of the RFID system [13]. Fitted with particular devices, called *transceivers*, capable of intercepting the transmission of radio waves, it is possible to decode the data contained within them without difficulty. And if this were not enough, some distributions of Linux programs available for sale, such as *Backtrack* and *OSWA Assistant*, are capable of neutralising the cryptographic protocol which protects the information contained in the *chip*. Even more simply, according to the BBC (the British television broadcasting station), it is possible to clone a travel document using a reader purchased on *Ebay* at the modest price of € 200.00. The equipment is in fact capable of decoding the

information contained in the RF tag and appropriating it, thereby eliminating any type of difficulty related to the creation of a new international passport. [14]

5. Conclusions

With this study, the authors have attempted to give an in-depth examination of aspects related to the diffusion, in everyday life, of so-called "intelligent" technologies.

The electronic passport might be seen to represent the very emblem of these applications. We have therefore highlighted the innumerable advantages it would bring to the general community, without overlooking the unavoidable ethical and practical problems which its use could cause.

Every new technology brings with it inevitable risks; we therefore need both an attentive control procedure and the adoption of application restrictions.

Regional Development Strategy

Abstract

The development policy promoted by the European Union is a policy of social and economic cohesion, based mainly on active development measures. Political and financial support granted by the European Union aims at achieving a higher level of development capable of delivering economic and social benefits both internally and externally.

Regionalization is a common trend of the evolution of territorial organization of European states and the regions that ensure decentralization of decision at the local, provincial or regional level have developed as a consequence of the high level of funds intended for economic and social cohesion across the European Union by eliminating and preventing imbalances between regions..

Key words: regional development, regional policy, social cohesion, development policy

J.E.L. classification: R10, R11, R19

Locating the economic activities in the territory is carried out mainly under the private interest that in principle is the making of profit. The consequences of applying this principle at local level are explained by the way the local councils exercise their power. Their scope of action withdraws from the areas reserved for private initiative, the adjustment mechanisms from a particular market being the ones specific to competitive markets.

In conditions of multi polarity of a decentralized economy, both the state and local collectivities are formed as autonomous decision centers for the realization of objectives of local or general interest, hence, as independent economic agents, partners among themselves and also private equity partners. The territorial councils have attributions such as ensuring free trade and

fair competition, protecting and supporting free enterprise.

The present reality highlighted the functionality, the effective adaptability of the competitive economic system, within certain limits (and failures) of the mechanisms of (self)adjustment of the market due to factors of influence from the sphere of entropic and antientropic measures. To that end we specify the appearance of: imbalances and disparities in economic growth rates; of accelerator factors of regional underemployment of the labor force, of environmental pollution, etc..

The development policy promoted by the European Union is a policy of social and economic cohesion, based mainly on active development measures. Political and financial support granted by the European Union aims at achieving a higher level of development capable of delivering economic and social benefits both internally and externally.

Regionalization is a common trend of the evolution of territorial organization of European states and the regions that ensure decentralization of decision at the local, provincial or regional level have developed as a consequence of the high level of funds intended for economic and social cohesion across the European Union by eliminating and preventing imbalances between regions[1].

According to the National Development Plan 2007-2013, the regional development priority is "to support the balanced development of all regions of the country".

Within the development of the National Regional Development Strategy NDP 2007-2013 there have been found the following problems[2]:

- inter regional disparities in economic and social development;
- increasing development disparities between the region Bucharest- Ilfov and other development regions;

- low degree of attractivity of most regions;

- massive decline of many cities;

Based on the found problems, it has been set the overall strategic objective of the National Regional Development Strategy to be: "The reducing of development disparities between regions and within regions (between different areas, urban-rural environment, urban areas and *adjacent areas*), at the same time with the stimulation of the development of urban centers with the potential of polarization of regional development "

The specific objectives of the strategy are[3]:

- increasing the competitiveness of regions as business locations;

- supporting the development of regional/local economies affected by industrial restructuring or traditionally underdeveloped;

- capitalizing on the tourism and on the cultural potential of regions and increasing the contribution of these areas in developing regions;

- halting the decline of urban areas and their revitalization;

- strengthening the capacity of local authorities to plan and manage the development.

Starting from the specific objectives of the Regional Operational Program 2007 - 2013 the priorities were:

1. improvement and development of local and regional public infrastructure:

- improving and developing transport networks and associated utilities;

- supporting and developing of the health and social services;

- rehabilitating and developing of the educational infrastructure;

2.supporting the development of regional and local economies:

- creating/developing of the business infrastructure;

- supporting the local business activities of of innovative character;

- supporting the innovative business services;

3. regional and local tourism development:

- rehabilitation of tourism areas, renovation of historic and cultural heritage;

- protection, rehabilitation of the natural heritage;

- supporting the income generating tourism activities;

4.supporting the urban development:

- supporting the integrated urban programs;
- improving the urban transport infrastructure, public utilities and related public services;

- rehabilitation of decommissioned areas into sites for the development of new business.

The fifth priority of the National Development Plan aims to promote balanced participation of all regions of Romania in the process social and economic development.

Romania's experience of transition to a market economy shows that market forces left alone, tend to unevenly distribute economic growth and employment opportunities. The result was massive migration to Bucharest, Timisoara etc., of the active population, where growth tends to concentrate.

In Romania there are the necessary conditions for the regional development policy to grow. Compared with traditional market economies, the inequalities are still relatively low, existing a network of urban centers in which it can be invested for the creation of regional markets and the educational level of the population is quite evenly distributed in the country.

Further efforts are needed to implement a regional policy to ensure a balanced participation of all regions in the country's economic development, regional development issues being addressed in the context of the broader objective of the NDP: realization of economic and social cohesion.

The priorities identified in the NDP on regional development plans proposes three specific objectives:

- combating regional and sub-regional disparities through adequate policies;

- combating the phenomenon of urban decline and revitalization of urban areas;

- creating jobs in marginal / disadvantaged areas.

Combating the process of deepening regional and sub-regional disparities needs to have as a result the maintaining of the current level of economic disparity between regions, and in particular the increasing disparities between Bucharest and the rest of the country, and, where possible, changing migration flows from Bucharest to other

areas of the country. This could lead to lower intra regional disparities by supporting the creation of local integrated labor markets and a better use of urban-rural economic relations.

Creating employment opportunities in marginal / disadvantaged areas refers to creating jobs in the new agriculture sector, in areas defined as marginal and disadvantaged, which could enable the realization of a minimum of economic activities across the whole country and thus resolving possible emergency situations in the social plan.

Achieving regional development requires an integrated strategy based on a combination of public investment in infrastructure, the allocation of financial support, consisting of direct support to companies and incentives for creating economic opportunities: in the marginal and in the disadvantaged area.

Regional development strategy needs to place greater emphasis on the public investment component and the improvement of the overall business environment. Efforts will be made for focusing direct support in some areas where this work is indeed necessary to influence the choice of the investors regarding the location of the new businesses (start-up) or to compensate other inefficiencies of the market.

The strategy focuses on improving the overall business environment in the regions through investment in transport infrastructure and supporting businesses and improving the basic conditions in which businesses operate. This means first of all investment in water supply systems and sanitation, as well as investments in improving recycling. They are regarded as basic conditions for attracting private investment and a better accessibility and communication. It is expected that these types of investments to positively affect business costs, and overall competitiveness[5].

Industrial parks are regarded as true drivers of growth at regional and local levels and at the same time, as the core of the urban growth poles. Focusing public investment in small towns will allow Romania to maintain its network of centers of consumption, many of them living on outside resources (farms, working abroad) as it presently happens, to centers capable of developing sustainable production sectors and services.

Another important component of regional development strategy is the investment in human resources, which completes the investments in creating a favorable business environment.

To achieve this objective, the strategy takes into account both the basic measures and the improvement of infrastructure and promotion of entrepreneurship and educational and professional training measures, which often have difficulty in accessing these services under current conditions.

The regional dimension of these measures will allow to take into account the specific needs of different areas and maintain a balanced and reasonable level of investment in school infrastructure across the country, aimed at keeping in the region, at least at current, quite close levels, the training of the human resource.

It is recognized that tourism offers the best, and in many cases, the only realistic prospect for economic development in marginal and underdeveloped areas. Therefore, for the capitalization of this potential are needed public investments to increase the attractiveness and accessibility of tourist areas with potential, adequately promoting them being a precondition for stimulation of private investment in these areas.

Thus, the North-East region will receive 708 million euros, the South East region, 575 million euros, and the South, 618 million. For the South-West region will be allocated 608 million euros while the West region will receive funds worth 449 million euros. For the projects implemented in North-West they will spend 524 million euros while the Central region will receive funding of 473 million euros and the Bucharest-Ilfov, 384 million.

To receive these funds, the applicants must prepare eligible projects or they will lose the funds, that can be allocated from one region to another depending on absorption capacity. These amounts do not include funds for technical assistance that will benefit all regions, the funds will be managed by the Managing Authority for ROP.

European forums are yet to rule on the Regional Operational Program.

In accessing the Phare funds that Romania failed to absorb in the pre-accession process, one of the targeted direction is regional transport. Projects will aim to improve or build new bypass roads and bypass roads linking national highways. The proposed infrastructure projects may receive up to 5 million euros each, plus 33% national co-financing. The grant may not exceed 90% of the total eligible project, the difference being covered by the project beneficiaries from their own resources or from donations and provided in cash.

It should aim to increase the quality of county roads and traffic safety measures in order to increase their rate of use. The specific eligibility criteria requires that projects of ring roads and bypass roads must demonstrate that they are included in the Urban Plan (PUG) of the city, in the County Spatial Plan (PATJ) or in the National Rehabilitation Strategy applicable in 2001 - 2015.

Applicants must make available to those who made the selection of projects, a CESTRIM study of counting of vehicles, if they wish to allocate funds for construction of ring roads and bypass roads.

The study must certify that by implementing the project it will increase the transit capacity and the saved time will be greater than 30% compared with the main transit routes across the city. The average daily traffic is greater than 2,000 standard vehicles, on the main transit routes and for heavy vehicles the figure must be over 150, while the daily number of conventional vehicles will exceed 1500.

Projects must be based on a census of traffic of transit routes attached to the Feasibility Study to demonstrate there will be reduced vehicle operating costs. Projects of this type can not be co-financed by other institutions or programs.

Targeted are the cities and towns with high levels of air pollution and those with high traffic, particularly trans-national trafficking. Priority is given to projects that aim to raise the level regarding the access to public transport, to improve access to the industrial areas or tourist areas. To be eligible, projects must have as its objectives, increasing the daily number of vehicles passing through the area and the volume of transported goods, reducing traffic in city

centers and decreasing the level of noise and air pollution.

The strategy was prepared in accordance with the principle of subsidiarity, which was prepared on the basis of Regional Development Strategies, developed at a regional level working in large partnership groups. The strategy has realistically taken into account the existing limited strategic and financial planning capacity at the local level, particularly in the less developed areas and therefore takes into account primarily, that the project is to be managed at local level and the central level is to conduct a consistent supervision of the whole program.

The ROP strategy complies with the National Strategic Reference Framework, contributing to achieving the global and specific objectives, regarding the reducing of disparities in economic and social development between Romania and other EU member states. The Regional Operational Program addresses the five priorities of the NSRF, being related to the majority of the development issues which it covers. In comparison with the EU-25, the regions of Romania are among the least developed and will take many years and significant resources to achieve convergence with other Member States. Based on what has been achieved to date through the investment in the pre-accession period, ROP aims to spur the development of the regions of Romania for the purpose of achieving convergence.

The Regional Development Strategy arises from key issues identified in the socio-economic analysis, namely:

- the concentration of economic growth driven by foreign direct investment around Bucharest and thus the emergence of capital city congestion problems;
- the recurrence of historical imbalance in development between the eastern half and western half of the country, due to the reorientation of trade flows and access to western markets, as well as the difficulties which the Western side of the country appears to have in connecting to global markets outside Europe ;
- the economic decoupling process of traditionally underdeveloped areas in the north and along the Danube;

- the existence of large areas of the country, whose future development is marked by labor shortages and a temporary phenomenon of massive migration;
- the loss of urban functions of many small and medium-sized cities, especially those mono industrial ones, a phenomenon generated by industrial restructuring;
 - the importance of accessibility as a key prerequisite for local development
 - the possible occurrence of an economic stagnation phenomenon in the mountains;
 - the limited experience of local authorities in the regional / local development management;
 - the socio-economic decline of many large urban centers and reducing their role in the development of adjacent areas.

It is obvious that the solution of these problems depends largely on factors that are outside the influence the ROP may exercise such as: primary sector productivity, industrial competitiveness, the competitiveness of productive activities, the existence of functional national transport corridors, well-qualified human resources and adequate administrative capacity. What ROP aims to create are appropriate conditions so that the above policies may have the highest impact at the local level, which requires a flexible approach, because the problems of development differs substantially within the region, impacting on intra regional economic and social disparities. In some cases, these disparities are extremely fluid and with recovery opportunities, as they are not chronic long as happened in the old market economies.

EU accession offers Romania the possibility of no longer considering the historic Danube as a boundary that prevents trade but rather as a waterway that creates opportunities for trade and promotes the mobility of the population; this is because the river can be used not only to connect Romania to Western Europe, but also as a way to link to the Black Sea, allowing opportunities offered by both the domestic and the globalization process and thereby providing an opening for the economies of those riverside counties that are suffering from historic economic underdevelopment, generated by their location along the Danube.

Increased labor mobility will be an inevitable result of the accession and the convergence of wages will increase further the role played by the existence and the quality of infrastructure (including social infrastructure) as a key factor that conditions the attracting of foreign direct investments. Many areas of Romania will have to face the consequences of underfunding of the public services if they wish to have a chance in the increasing competition in the increasingly mobile international markets.

However, the political leaders need, which are not to be overlooked for the near period and the next election, may be inconsistent with the needs of those that invest, needs that to look a long time and after tax income from investments. The search for funds by politicians to provide benefits to their supporters can use people's inability to meet short-term tax increases.

Abstract

To achieve the objectives of regional development, local collectivities must have financial resources. These resources come mainly from local taxes, from the revenues of their own activities, are thus, directly proportional to the volume of economic activity in the territory. Therefore, for the local collectivities a particular importance is the attracting of new businesses along with the development of the existing ones

Key words: regional development, regional policy, social cohesion

J.E.L. classification: R10, R11, R19

In terms of declining economic activity, economic recession or crisis it is extremely difficult to attract new businesses in underdeveloped regions and expansion of the ones already located in those areas.

Therefore, the main features of regional policy instruments refers primarily to the creation of favorable conditions for attracting private investment in terms of reduced public funding sources. Of these features we present the following:

- The instruments of intervention in the evolution of regional variables are found, usually in the forms and procedures of the management of government consumption and the expenditures from the budget of other public institutions in the sphere of local taxes, public investment and subventions for public and private investments .

Depending on the specific economic policy promoted, the presented instruments, may be related (filled) to other particular instruments.

Aid for regional development and financial incentives are granted under joint programs, national and regional.

- In countries with experience in the field, the instruments of regional policy are derived from instruments of economic policy (fiscal, budgetary, monetary) and can be divided in two broad categories:

1. Direct intervention to locate and develop activities or for endowment of the territory with certain utilities:

2. Incentives for development

In the category of direct interventions, fit these measures:

- government participation in the development of economic and social infrastructure elements;

These elements of infrastructure are made be the local collectivities. The central government shall assist local communities in the form of investment subventions to: development of the transport network, creation and improvement of water distribution network, electrical and thermal energy, etc..

Association of public and private capital for making investments, particularly for developing local interest services. This association can be made in imposing the condition that the investment does not lead to major labor force movements;

The stimulation of locating activities and local development can be achieved by regional policy measures, which by nature are divided into two classes[1]:

- a) the providing of financial incentives;

- b) the adopting of compensation measures to eliminate or reduce the additional costs generated by locating activities in a given space.

- a) In most countries, one of the main instruments of regional policy is to grant financial incentives for public and private companies to encourage and stimulate the location or development of sustainable activities in certain areas to prevent their decline.

The main characteristics of the group of financial incentives for regional development policies are:

- budgetary funds which are one of the most powerful instruments of regional policy;
- there is no uniformity from one country to another or in relation to the type of incentives offered in support of regional development, nor in the level of support provided or size of the beneficiary due to the particular circumstances of each country;
- the conditions for financial aid granted to enterprises vary from country to country (the company must belong to the assisted area or region; it needs to work in the nominated region, to benefit from the project for which assistance is sought, it must be compatible with the general and / or specific regional policy, etc..)
- financial incentive schemes are selective, so that regions facing the most serious problems are to receive the most aid;
- financial incentive schemes are modified periodically based on the interests of the authorities, the developments and results;
- to reduce the overall incidence of imbalances in the most deprived regions or areas, the trend observed in different countries is that the incentive measures and financial incentives become more selective over those granted automatically - it requires multi delimitation of assisted regions.

As is clear from international practice, the main types of financial incentives include: investment premiums (a percentage of the total cost of investment) in assisted areas, granted subject to demonstrate the basic effect (the ratio between supply and demand), grants for investment definitively granted for public or private establishments to mitigate or offset the costs to encourage actions (the creation of developed enterprises, rationalization and reorganization of existing units); transfer premiums welcome subventions for firms (location premium) ; giving loans on favorable terms (long-term interest rate to be below those prevailing on the capital market), providing loan guarantees, etc..

- providing facilities for the purchase or rental of land (premiums: subventions (rebates) for prices, loans on favorable terms, etc.); providing tax exemption from payment of customs duties (to encourage investment), providing local tax incentives (tax cuts on investments, income, profits, etc.) for a number of years, granting preferential treatment in the award of market segments, granting special permits depreciation regime (eg, acceptance of accelerated depreciation allowances and / or exemption from taxes of the amounts from the depreciation of certain elements of fixed capital), etc..

b) Compensation measures on the removal or reduction of additional shares generated by the location of activities in a certain space.

Obviously, any measure to attract investment in certain areas aims to reduce or offset the actual costs of opportunity costs.

There are compensatory regional policy instruments aiming to eliminate some costs directly related to operating, training, resettlement and labor force use, transport, etc..

Among the countervailing measures found in the regional policy of various countries we can identify:

- aid granted to reduce operating costs;
- subventions for labor charges (extra benefits given in certain areas);
- premiums for the creation of each job (or jobs for certain majors or certain categories of applicants - youth, women etc..).
- grants to support certain social security or social services;
- aid to support labor mobility and resettlement (transfer premiums or allowances, subventions and indemnities for transfers etc..).
- aid granted for the training of employees;
- subventions for transport and other public services, etc..

Direct interventions, financial incentives or compensatory measures are part of the range of tools that facilitate the achievement of financial policy objectives.

The effects and effectiveness of these instruments are difficult to isolate and evaluate.

The role of these regional policy instruments, from an analysis of OCDE countries, is the following[3]:

- a) measures the ability to exert a considerable influence on the profitability of companies throughout their lifetime;
- b) the scope of measures must be broad enough to exert a substantial effect on the economy of the regions concerned;
- c) public authorities must ensure that financial incentives and compensatory measures are limited, they having only the role of "points" proportionate to the desired results and their structure;
- d) a system of financial incentives can lead to results contrary to the aim pursued, if it is too large or too dispersed to countries and is therefore likely to attract upward pressure on the initial amounts over what is possible.

To achieve the objectives of regional economic development strategies, given the limited character of the volume and structure of financial incentives and compensatory measures, each country (defined as a complex and open system) calls for structural measures to international organisms it joined or is hoping to join. Referring to the European Union in the context of structural complementary regional funds we can say that it raises two issues: the need to ensure the coherence of European Union regional policy in the context of the particularities of countries and regions that apply this policy; the insurance that it will be taken into account the wide variety of regional problems in the European Union and support the most urgent in the context of fairness to member or aspirant countries.

To achieve the objectives of economic policy promoted by various countries, given that national financial incentives are limited (size and structure is dependent on the level of development) to the financial incentives granted by the European Union (or other international bodies). In the category of these financial incentives are the following structural funds:

- European Regional Development Fund (ERDF);
- European Social Fund (ESF);
- European Agricultural Guidance and Guarantee Fund, Guidance Section (EAGGF-O)

Financial incentives took the form of aid for productive investment, the employment of available labor force and harmonious development of regions lagging behind. These financial incentives are granted as subventions, grants, allowances, bonuses or any other sources of non-refundable character, discounts on goods supplied and services rendered by the state, the cancelation or reduction of debts to the state, cancelation or reduction of interest loans taken with preferential interest, granting of state guarantees, exemptions, reductions or exemptions from customs duties and other taxes and duties depend on these, reductions or exemptions from taxes and financial obligations, discounts or exemptions to pay increases delay, etc..., amortization and other fixed facilities, subventions for the use of labor force and its employment, facilities granted to improve infrastructure[4].

The granting of such state aid, both nationally and locally, is made following impact assessment of their allocation from the point of view of efficiency of spending public money and in terms of competitiveness taking into account the nature of state aid and the specific way to quantify it. All these are made to identify the degree of realization of the main objective pursued, as well as to identify the major recipients of state aid.

In modern economies, including in EU practice, there are many disturbing factors that call into question the "fairness" of the prices charged by firms with different locations and how that affects the competition and the quality of competitors. From the long list of circumstances we remind some as:

a) differences that exist between private and social costs (seen on the product, the fields, on the different types of producers and consumers). The greater the differences are, the more affected is the quality of the competitive environment. Beyond the inherent differences arising from externalities (positive and negative), the quality of the competitive environment and hence the competitive tender prices are influenced by the legal framework on: taxation, environment, business finance, social welfare, fiscal policy, trade customs;

a) existence of public goods (local, national, european) different in time and space, different weight that they hold in total consumption factors. In some countries and industries, the consumption of these goods is high which reduces production costs. In others, such inputs are small and thus there are relatively higher costs;

b) the public actions (and private) that establish the rules and standards (quality, technical, environmental and population protection) disrupt the accuracy of export prices by:

- additional costs that rise to meet non tariff conditions imposed by partners or legislation;
- artificial reduction of the scale economies due to lower production to meet explicit quantitative limits (quotas, "voluntary" limitations, quantitative thresholds, etc.), and non-tariff requirements specific to every national markets to where the exports are bound;
- additional costs that customs procedures and more sophisticated control impose that have proliferated in the contemporary conditions in the EU (documentation, quality surveys, certificates of origin, specific labeling and packaging etc.)

c) regulations regarding: the access to local public services, state aid facilities on the fees, taxes and other tax liabilities (deferred, rescheduling, tax reductions and exemptions), plus various agreements, abuse of dominance etc.

d) lately, with the price competition (selling competition), is amplified the non-price competition (quality, supply differentiation, attraction and "capture" of buyers) the advertising having a determinant role. Advertising as a tool of competition and a component of the competitive environment has an important role when it is diverse and extensive, and his targets are makers of acquisition: workers in marketing departments (for the needs of companies), children (toys and some food, clothing), women (for convenience goods and food), men (for cars and some consumer durables), physicians (especially for medicines and equipment and miscellaneous supplies) and so on.

A key role in the competition - beyond price – has innovation.

Innovation is one that provides sustainable competitive advantages that firms possess.

As mentioned, the competitive environment is a social creation, founded on the legislative and organizational framework - promoted and applied by governments, national and european - with the involvement of private operators and market structures.

The nature and consistency of policies (economic, social, environmental, etc.) and the legal framework (developed and applied equally) ultimately determines the quality of the competitive environment, for they depend on the functioning of the market, rewards / restrictions to private operators, the way that the property institution is represented in the social consciousness. Through the quite restrictive policies can be build into policies and anti competitive actions which are promoted by the employers that with the support of the authorities. In the short term, monetary policy and exchange rate exerts a strong influence on competitiveness, as direct taxation influences long-term exercise[5].

Assessing the economic policies in terms of economic interests and of the short to medium term, they exercised a contradictory influence on the competition. Compared to the restrictive economic policies, negatively appreciated by the companies, the market reaction is immediate: the most rapid response to poor economic policy decisions have the international capital markets, "the electronic herd", ready to create panic at the first sign of economic and political weakness. Instead, it takes many years for lax economic policies to gain the trust of the market (primarily capital one) and to improve the competitive environment[6].

The issue of economic structures can be approached from many angles. Here, our analysis is confined to market structures, seen in terms of the number and the potential of the producers, buyers and brokers. They are subject to technological configurations, assortment, of branch and territorial, of communicability and the connections between different markets, from national and international market (European Community). The competitive environment is friendly when the number of agents is high, the supply is diversified, the demand is dynamic

and heterogeneous, the entry-exit barriers are low, or easily overcome due to increased mobility of production factors (territorial, branch and items), adaptability and their substitutability. An defining element of the competitive environment in terms of economic structures is the configuration of system of companies including business class configuration in terms of size (force) and performance is very relevant.

Abstract

The purpose of our paper is to analyze the total healthcare expenditure of the EU-27 member states in relation to different explanatory variables. The only strong direct correlation we could determine statistically is that between the per capita healthcare expenses and the per capita GDP. All panel data models were estimated in Gretl. Results have been interpreted and commented.

Key words: total healthcare expenditure, panel data, linear regression, correlation.

J.E.L. classification: I10, C20.

1. Introduction and literature review

Healthcare has been defined as the prevention, treatment and management of illness and the preservation of mental and physical well being through the services offered by the medical, nursing and allied health professions.

Because health is an important priority for Europeans, many of today's European healthcare policies include not only cures but also prevention and detection. A new health strategy "Together for Health: A Strategic Approach for the EU 2008-2013" was adopted in 2007, putting in place a framework to improve health in the EU through a value-driven approach, recognizing the links between health and economic prosperity, integrating health in all policies, and strengthening the EU's voice in global health. The White Paper sets out a coherent framework and a health strategy, giving direction to community activities in health,

and establishing fundamental principles for action on health.

The weight of the current healthcare expenditure within the GDP of a country has been growing rapidly in almost all developed countries. Although these represent a major public concern, little aspects are known about the factors that determine the rapid growth of these expenditures. Thus, in 1994, Hoffmeyer and McCarthy [5] concluded their research by affirming that "there was only one clear and well-defined statistical factor that influenced the healthcare costs, namely their correlation with the GDP. Other robust and stable correlations had not been found yet". Actually, over the past thirty years research on the determinants of healthcare expenditure has focused on evaluating the strength of the relationship between the volume of public healthcare spending and the GDP. Attempts to determine other suitable exogenous variables have failed, despite the fact that the correlation between public healthcare spending and GDP doesn't explain very much in terms of their causal relationship. Even the apparent obvious factor of the weight of population aged 65 and above in the total population hasn't been proved to contribute and to explain the public healthcare expenditure to a certain extent, except for a very limited number of studies, such as Hitiris and Posnett [4] and Di Matteo [2]. The investigations upon the explanatory factors of healthcare expenditure have been updated by Hartwig [3] and Baltagi and Moscone [1].

After reviewing the literature written on the field, it may be concluded that, despite the intensive research efforts, little is known about the potential exogenous variables that

would explicit the healthcare expenses of a nation as an endogenous variable [6].

2. Research methodology

There are few empiric papers that estimate the healthcare expenditure of a nation, most papers directly correlating them with the country's GDP. The total health expenditure measures the final use of resident units of healthcare goods and services plus gross capital formation in healthcare provider industries, being the sum of public health expenditure and private health expenditure. We've simulated the per capita total healthcare expenditure (both public and private) for the EU-27 member states with the help of a linear econometric model, by considering the per capita healthcare expenditure of a country as an endogenous (dependent) variable.

Firstly, the per capita GDP of a country was used as an exogenous (explanatory) variable, as follows:

$$\text{HealthcareExpenditure} = \alpha + \beta * \text{GDP} + \varepsilon$$

Our study uses Eurostat data for the 27 member states of the EU. The data are real annual data, expressed in euros per capita, for the 2003-2008 time interval. The total number of observations is of 162 (the 27 member states over the six year period of time). The estimations were carried out using the panel technique and the coefficients were at first estimated with the least squares method for panel data, further on choosing a fix effects model.

For the first simulation, the per capita GDP has been chosen as the single dependent variable:

$$\text{HealthcareExpenditure}_{it} = a_0 + a_1 \text{GDP}_{it} + \varepsilon_{it}$$

where:

$\text{HealthcareExpenditure}_{it}$ = the total per capita healthcare expenditure of country i , year t ;

GDP_{it} = the per capita GDP of country i , year t ;

ε_{it} = the error (an aleatory variable that

synthesizes the effect of other factors besides the ones included in the model as explanatory variables).

For the next simulation, besides the per capita gross domestic product, we've introduced the weight of the population aged 65 and above in the total population as another explanatory variable, which was previously proved significant in a reduced number of studies, like that of Di Matteo [2]. The model is as follows:

$$\text{HealthcareExpenditure}_{it} = a_0 + a_1 \text{GDP}_{it} + a_2 P_{it} + \varepsilon_{it}$$

where:

$\text{HealthcareExpenditure}_{it}$ = the total per capita healthcare expenditure of country i , year t ;

GDP_{it} = the per capita GDP of country i , year t ;

P_{it} = the weight of population aged 65 and above in the total population of country i , for the year t .

3. Results and comments

For the first simulation, the linear simple correlation coefficient is very close to 1 (0.915840), thus confirming the strong correlation between the endogenous variable and the exogenous variable, and the coefficient of the exogenous variable is significant with a 1% chance of rejecting the null hypothesis. A one unit increase of the per capita GDP determines an average increase of 0.0815332 units for the per capita healthcare expenditure, in the EU-27 member states.

When sampling for Romania, we obtained that:

$$\text{HealthcareExpenditure}_{RO,t} = a_0 + a_1 \text{GDP}_{RO,t} + \varepsilon_{it}$$

where $a_0 = - 8.36389$ (0.1210), and $a_1 = 0.0278349$ (0.0000***), with $R^2 = 0.995466$, pointing out an extremely strong correlation between the two variables. Thus, at a 1 euro increase of the per capita GDP, the per capita healthcare expenditure increase with

approximatively 3 eurocents.

For the second simulation, we obtained a multiple linear correlation coefficient very close to 1 (0.917984), thus confirming the strong correlation between the endogenous variable and the explanatory variables. Moreover, the coefficients of all the exogenous variables are significant with a 1% chance of rejecting the null hypothesis when it is true.

As expected, there's a direct correlation between the per capita real GDP and the per capita real healthcare expenditure, and an indirect correlation between the weight of population aged 65 and above in the total population and the healthcare expenses. At a one unit increase in the per capita GDP (1 euro), the per capita healthcare expenditure rise on average with 0.08154 units (0.08154 euro), while the other explanatory variable doesn't modify.

As opposed to this, the obtained results reveal that a one percent increase in the weight of the population aged 65 and above in the total population would lead to an average decrease of 31.59 euros of per capita healthcare expenditure, which is not too realistic. Paradoxally, it seems that this age segment isn't among the ones that would explicit the evolution in healthcare expenditure.

When performing the analysis on Romania's sample, we obtained that

$$HealthcareExpenditure_{RO,t} = -217.108 + 0.0254074 GDP_{RO,t} + 14.9587 P_{RO,t},$$

with the corresponding thresholds of (0.3010), (0.0014***) and (0.3166) respectively, while R² gets to be 0.986467, a little lower than for the first sample.

For the EU member states we obtained the following regressions:

$$(1) HealthcareExpenditure_{it} = -409.221 + 0,08153 GDP_{it}$$

$$(2) HealthcareExpenditure_{it} = 90.46 + 0,08154 GDP_{it} - 31.59 P_{it}$$

These estimations reveal the dependency relationship between the healthcare expenditure and certain macroeconomic aggregates that may be their approximation, according to the data synthesized in Table no. 1, through the least squares method for panel data (OLS), and the fixed effects model (FEM), obtaining better performances for the latter, as follows:

Table no 1. The estimation of healthcare expenditure

Note: Within parentheses there are the p-values, and *** designates the 1% significant coefficients, ** designates the 5% significant coefficients while * designates the 10% significant coefficients. Estimations were carried out using the panel technique and the Gretl software.

The graphic representation of the data for the optimum model i.e. the fixed effects panel is represented in the following figures. *vI* represents the total healthcare expenditure, expressed in euros/per capita, annual values for the EU-27. The 27 cross sectional units are represented processing the data with the Gretl software. The length of the times series is of six years (the 2003-2008 time interval), i.e. a total number of 162 observations; furthermore, the experimental values are represented in red + and the ones adjusted by the optimum chosen model in blue x.

Figure no. 1. Experimental values of the European per capita healthcare expenses and the ones adjusted through the FEM model

Source: Authors' processing in Gretl

Figure no. 2. Experimental values of the European per capita healthcare expenses and the ones foreseen by the FEM model

Source: Authors' processing in Gretl

Moreover, among the countries that have a high level of healthcare expenditure there are Sweden and Ireland. Then, among the countries whose real healthcare expenditure is situated in the 2.000-3.000 euros/per capita annual interval there are Holland, Finland, Switzerland and France. According to Văidean [6], a precise correlation among the level of these expenditures and the type of healthcare system held by the country cannot be established: Sweden, Ireland and Finland mainly finance their healthcare system through taxes while Holland and France finance their healthcare system through social health insurances. But these countries also have a very well fundamented and developed private healthcare sector.

Unfortunately Romania is situated on the penultimate position of this top, annually allocating for the healthcare sector less than 200 euros per capita, while Bulgaria is situated on the last position of this top, with less than 100 euros per capita spent on healthcare. Summing up, the healthcare expenditure of a country seems to highlight the development level of a country even more.

4. Conclusions

The connections between mass economic phenomena are characterized by the fact that one phenomenon or another vary under the influence of a complex range of factors, some of which have a crucial influence and others are of a secondary importance. We've tried to identify the exogenous variables that would explain to a certain extent the total healthcare expenditures of the EU-27 countries.

Our six year panel study on the EU-27 total healthcare expenditure proved that they are explicated to a great extent by the GDP of the member state. Other strong correlation variables were not found statistically significant, this being the purpose of our future research in the field.

Nevertheless, the competence for the organization and delivery of health services and healthcare is largely held by the Member States, although the EU has the responsibility to give added value. And although many would help the countries to have a healthier population.

studies [6] have previously shown that the population health status depends on the combined effects of several factors, certainly if health sector performance improved, it

Management Control and Remuneration System

Vărzaru Anca Antoaneta

Vărzaru Mihai

University of Craiova, Faculty of Economics and Business Administration

varzaruanca@yahoo.com

Abstract

Many businesses still adopt pay practices in a sequential manner, without regard to strategic vision and organization values (Tremblay M., 2001). To earn the epithet "strategic" management remuneration must be aligned to the strategies of the business and be in synergy with the other human resource management practices. Thus, firms face more choices in terms of remuneration policies. One of the basic principles of the remuneration policy is that of its periodic review, due to its short life cycle. Earnings management implies the existence of diagnostic tools to monitor developments, to anticipate the drift and track environmental changes. This paper discusses the new issues affecting the purposes and pays the balance of a system of control and management role in seizing and removing them. Thus this paper includes social balance sheet and a number of potential indicators of how to refer matters to ensure compatibility between business strategy and social policy.

Key words: remuneration policy, management control, diagnosis, audit of earnings, external competitiveness

J.E.L. classification: M12, M41

1. Earnings Control

Social audit practices have evolved along the lines of financial audit and, from this point of view, occurred in the specific management activities of social function, such as remuneration, training, recruiting etc. Thus, the social audit has become a dimension of internal audit and within the audit of remuneration was a promising start (Igalens, 2002).

The more the number of firms increases, the more it becomes imperative to the presence of some objective analysis of earnings. If in small organizations an analysis of wages can be achieved through a subjective and individual knowledge, to a number of over one hundred employees this is not possible, and thus it requires having collective data as objectively as possible.

The finalities of remunerations audit can be considered as follows:

- the examination of the system and of remuneration policy, of some issues that are relevant for the good of the two elements, can be mentioned as examples the policy enforcement, compliance with conventional instructions;

- the forecast of evolution earnings by through can be identified risk areas, outline the wage bill etc.;

- the understanding and action on the system and remuneration policy, which seeks to know reality in designing an action plan, the way in which the pilotage of policy and implementation is made, and, where appropriate, of individual and collective adjustments.

Another problem that must be considered when carrying out an audit of earnings regards *the determination of the angle from which you phase out the analysis*. Thus, the diagnosis (audit) may address one or more of the following areas:

- legal and social field, through which is pursued their legal compliances;

- economic and financial field, to optimize the benefits, to control the registered drift control in payroll;

- managerial field, which aims the internal equity of basic wages, identification of explanatory factors of wages etc;

- marketing-communication domain; in this respect audit examines the links between remuneration policy, recruitment of personnel and social image of the

organization, the impact that remuneration of managers has on the social rating etc.

Making the best condition for an audit and remuneration is dependence on accurately defining the perimeter of the analysis. From this point of view has to be precisely defined the content (basic wage and variable wage alone, benefits etc.) and its scope (all employees, a geographic area, a service, a subsidiary etc.). The status and the system developments and remuneration policy are reviewed regularly through groups of indicators that are included either in the social balance sheet or are belonging to audit or remuneration diagnosis.

Social balance sheet is a unique document that contains the main digital data that allow assessment of the firm's position in the social field, recording achievements and measure changes that occur during the previous year preceding and the current situation in the previous two years. It contains information about jobs, about their remuneration and other costs, about the conditions of hygiene and safety, other working conditions, training, professional relationships, and living conditions of the employees and their families, to the extent where these conditions depend on the company.

Several European countries (France, Germany, Italy, United Kingdom etc.) adopted such a social instrument for companies in excess of 300 employees. Indicators of wages that can be identified in the social balance sheet are presented below in table 1.

1. In addition to these indicators, remunerations' audit calculates and analyzes the trend of a general indicator of balance, ie the relative importance of wages, with the benchmark value added or turnover of the company.

Table. 1. Remunerations and social balance sheet

No	Group of indicators
I.	The level of earnings
1	Levels of remuneration / total annual wage bill Total annual payroll includes all the taxable Monthly average amount calculated as the ratio between monthly total herd (all employees enrolled in the herd at the end) and the number of

	months (12)
2	Average remuneration / permanent effect
II.	Companies with more than 2000 employees
3	Average monthly remuneration = amount of wages granted in a year / paid employees The number refers to paid employees who worked 8 hours/day all year round
4	Grid earnings (at least six groups are distinguished)
III	Hierarchy
6	Superior decile/inferior decile = average earnings of 10% of the highest paid employees / average remuneration 10% of the most poorly paid employees The number refers to the employees who worked 8 hours/day all year round
7	average earnings of senior staff / average earnings of workers
IV	Structure
8	The percentage of workers whose salary depends, totally or partially, on performance

Source: Martory B., Contrôle de Gestion Social Vuibert Edition, Paris, 2007, p.37-38

This indicator plays the importance of wage commitments and performance of personnel development. Comparisons of this indicator are made on the dynamics, a few years earlier, in the organization, or with the values registered by competitors, with the media of the industry, etc. If this indicator is degraded (ie, where it grows), it requires a thorough analysis of its effects on the line of profitability and trajectory. Its' mode of calculation is relatively simple:

$$P_s = \frac{\sum_{i=1}^{nj} si \times ni}{VA} \quad (1) \text{ or}$$

$$P_s = \frac{\sum_{i=1}^n ri \times ni}{VA} \quad (2)$$

$$\text{or } P_s = \frac{\sum ri \times ni}{CA} \times (3), \text{ whereat:}$$

P_s - the relative weight of wages,
 s_i - wage i ,
 n_i - number of employees with salary i ;
 r_i - remuneration i , including social and related expenses;
 VA - value-added;
 CA - turnover.

This indicator can be calculated on categories of personnel or jobs, on types of subunits.

2. *Information about wages fund and its' structure.* Developments in wages fund can be analyzed by three significant indicators:

- *the sheer size of the wage fund and its evolution*, which can be decomposed into the specific part related to permanent employees and employees with labour contracts of limited duration;
- *the share of wages fund in total costs and its evolution*, calculated with the equation:

$$I_{FS} = \text{Wages fund} / \text{Total costs} \times 100;$$

- *wages fund structure (of its' components)*, which can be given in absolute values of remunerations, various bonuses, employers' social costs, or percentages of the total.

3. *Wages and costs level.* Most indicators used are:

- *medium wage (\bar{S})*, calculated with the equation:

$$\bar{S} = \text{sum of annual earnings of permanent employees} / \text{number of employees}$$

- *the median wage (S_m)*, as determined by the statistical procedure known.

The two indicators are determined by professional categories (for external comparisons) or types of jobs within organization, by location or budgetary subunit, by sexes etc.

- *average salary cost (\bar{Cs})*, calculated by category or budgetary subunit, is calculated with the equation:

$$\bar{Cs} = \text{cost of hours worked, the interim, the extra/ number of hours worked, the interim, additional}$$

- *earnings hierarchy*, which is calculated at organization level, subunit, or job category, with the equation:

$$i_r = \text{minimum wage} / \text{maximum wage}$$

- *the overall magnitude of earnings (a_r)*, leading indicator, for it calculation using the following relationship:

a_r = average salary or the median of lowest paid jobs/ average salary or the median of highest paid jobs

- *the level of social commitments* that can be measured and assessed through various indicators and highlights the importance of peripheral elements of remuneration, such as:

- share of premiums that are paid monthly to wages fund;
- the importance of social work in relation to wages fund;
- the benefits in kind;
- the importance of complementary social protection, provided over the legal minimum.

2. Structural control

This type of diagnostic aims to assess the hierarchy, composition and evolution of earnings, characterizing the system of remuneration and providing a basis for comparison with other competitors in labor practices, in branch etc. Wage structure is a key element in the assessment of a system and remuneration policy.

Regarding the individual structure, the information system should provide for a specific individual or an average salary of a category, pay level and progress on its five components: base salary and bonuses, remuneration for employment mode job, legal peripherals, benefits in kind and more remote peripherals. Collective examination of remunerations refers to the structure and the hierarchy of categories of personal earnings that are used relatively homogeneous labor practices. It seeks to control the architecture of remuneration system of the enterprise and the way this architecture evolves. The structure is characterized on the one hand, with a deviation of earnings in the same level of employment, performance or between

different average and median hierarchical levels.

The structure is assessed by viewing the incidence of various elements that determine the remuneration level, such as the degree of appreciation for employees, registered length, hierarchical level in a post.

In practice, it is associated, in schematic form, to a batch or continuous variable, representative for the impact factor and level of real wages to be paid. The structure will appear in two forms:

- *scheme of progression*, representing different levels of remuneration in terms of explanatory variables and evolution in wage levels. This grid is representative for the extreme possibilities of minimum or maximum wages, where wages are positioned.

- *cloud of points*, linking all real earnings in terms of wage levels. In practice is used a curve adjustment, which translates the trend of earnings development.

Regarding the control structure, it is clear that there is no type-structure that is always optimal, as a remuneration system is a variant translation of human resource management. Therefore, management control is exercised at the level of consistency that exists between:

- real pay system and prior options in terms of system architecture;
- the calculation of the earnings of borderer categories;
- developments of the system of remuneration and human resources management;
- market practices and organizations' form of remuneration.

An illustrative example is provided by J-M. Fleury who classify the forms of remuneration according to three main goals of modern wage policy, ie security, motivation and association. This pyramid allows you to view strategic goals that are associated to wage policy.

Abstract

The market economy refers to the implicit presence of a banking system which could ensure the mobilization of all the monetary resources of the respective economy and their temporary orientation towards the development of efficient economic activities.

The financial risks originate in the impossibility of foreseeing the evolution of the variation of the financial and banking risks. When employing their resources, the banks are confronted with a series of risks determined either by the quality of the organization providing the loan or by the general economic evolution or by the general structure of the bank.

For those banks operating in Romania, the risks are even more evident due to the hostile environment in which they operate, but also due to the specificity of the Romanian banking system which is still evolving and adapting to the competitive stringencies of the market economy.

Key words: crisis, credit risk, bad loans, banking supervision

J.E.L. classification: G21

The financial risks originate in the impossibility of foreseeing the evolution of the variation of the financial and banking risks. When employing their resources, the banks are confronted with a series of risks determined either by the quality of the organization providing the loan or by the general economic evolution or by the general structure of the bank.

The market economy refers to the implicit presence of a banking system which could ensure the mobilization of all the monetary resources of the respective economy and their temporary orientation towards the development of efficient economic activities.

By means of their activity of collecting financial resources and at the same time investing them in those institutions which have temporary supplementary needs, the banks fulfil an important role acting as an intermediary. In this respect, the credit becomes an active instrument in the stimulation of economic development since it encourages the emergence of certain phenomena according to the objectives that are to be followed in perspective.

For those banks operating in Romania, the risks are even more evident due to the hostile environment in which they operate, but also due to the specificity of the Romanian banking system which is still evolving and adapting to the competitive stringencies of the market economy.

Detecting the potential banking risks presupposes familiarity with the emergence and evolution of the release factors. The quantification of their manifestation parameters and the tracking down of those indicators which can lead to their identification are very important.

Due to the authentication and prudential monitoring norms of The National Bank of Romania, the **credit risk** is defined as “the risk of recording losses or of not making the estimate profits as a consequence of the inobservance of the promissory notes.”

From an economic agent’s point of view, the *credit risk* is defined by means of the losses registered because the advance cash flow was not collected till due as a result of

the degradation of the *debtor's crediting quality*. From this perspective, the credit risk has two coordinates: rating the risk and its quality.

Rating the risk shows the kind of loss the creditor has suffered as a consequence of the debtor's inability to refund the credit whereas *the quality of the risk* results from both the possibility that the payment may take place and from the guarantees which can cut down losses in case of non-payment. The impossibility of refunding a debt represents an insecure event. In addition, the future exposures are not known for a fact till due because crediting on the basis of refunding programs established according to solid contract clauses is to be applied only in a limited number of situations. The advance refunding of the outstanding loans displays a credit risk because in this situation the bank has to ensure a refinancing of the unattainable income and to cover the expenses generated by the credit granting.

Starting from these assumptions, the credit risk could be divided into three types of risk: *default risk, exposure risk and recovery risk*.

The Default Risk

This risk resides in the probability of non-payment of an outstanding debt. There are several possible definitions for *non-payment*: failure to keep to a payment bond, violation of a convention or economic non-payment. The default risk is proclaimed when the scheduled payment has not been carried through in a minimum period of time from the due date. *The economic non-payment* takes place when the economic value of the debtor's assets decreases beyond the value of the outstanding liabilities, a situation which can stop the debt repayment.

The deterioration of some economic and financial indicators as compared to the assumed level at the credit contracting date could be associated with *technical non-payment*. This non-payment usually triggers negotiations even if the failure to reimburse the credits till due does not jeopardize the debtor's creditworthiness. In certain situations, the bank can even make use its right to ask for a prompt reimbursement of all outstanding debts.

The probability of non-payment cannot be directly measured but one can use the historical statistics of internal non-payment, of the rating agencies and of the central

authorities. The most representative types of ratings are: the rating of the current debts, the emitter's rating and the industry rating. In most of the cases, the rating agencies assess the quality risk of a debt which is conditioned both by the probability of non-payment and by the possible recovery in case of non-payment.

The Exposure Risk

The exposure risk quantifies the degree of uncertainty regarding the borrowed sums. If the credit is reimbursed according to a firm contract program the exposure risk could be considered reduced or insignificant. Unfortunately, this thing does not hold valid for all crediting lines. If the crediting lines allow the debtor to access them whenever he wishes according to his needs and a maximum limit established by the bank, then the bank's risk of exposure is considerable.

The Recovery Risk

In case of non-payment, the recovery is not predictable. It depends on the type of non-payment and other factors such as: the debtor's guarantees and the type of these guarantees which can be correlated with those of a third party. A non-payment does not mean that the debtor will never pay but draws the initiation of certain actions such as renegotiation or the incumbency to reimburse the outstanding loans. If no corrective action is to be taken into consideration then legal procedures step in: the legal instrumentation of the guarantees (which differ according to the type of guarantee accepted) and the foreclosure of the guarantees.

For the assessment of the credit risk Basel II proposes two alternatives:

- the use of the standardised approach according to which the credit risk is cast up by the central bank for each type of assets on the basis of some fixed risk intensity in relationship with the credits typology.
- the use of internal models with two variants, basic and advanced internal models, which allows the bank to assess the risk according to each investment in part. The capital demands are designed according to four parameters of risk: the probability of non-payment (PN), loss given default (LGD), exposure at default (EAD) and exposure maturity (M).

The experience of the banks in Romania has proven that in time, the credit risk has represented the main risk which the Romanian banking system faced against the expansion of the crediting activity since approximately half of the assets are concentrated in credits.

The global financial and economic crisis has strongly influenced the evolutions from the manufacturing and financial sectors in Romania especially during 2009 and 2010.

This interval has reconfirmed the depression tendency of the non-governmental credit starting in the first trimester of the 2008 in spite of some stimulating measures adopted by the central bank. This is an ongoing phenomenon on the credit market and represents a serious challenge for both the banks and the authorities.

A growing vulnerability of the Romanian banking system is represented by the decrease of the credit portfolio quality which has fully manifested itself in 2009 and 2010 and still persists at present against the background of the economic recession. One can add the supplementary burden which the debtors who have contracted currency credits and are not ensured against the currency risk have to support. Even if the outstanding debts are at a manageable level, their growing rate constitutes a reason of worry for the financial stability.

Non-governmental credit contraction in the period 2009-2010 occurred on reducing both the fund supply and demand for loans. In relation to the supply of credit, the determining factor has been represented by the perpetuation of the banks' aversion to risk, despite the measures adopted by the central bank in order to encourage sustainable restart of crediting (reducing the rates of minimum compulsory reserves applicable to the credit institutions' liabilities in lei and in foreign currency, reducing the monetary policy interest rate, amending some stipulations of the bank prudence rules). In the context of these measures, to which one can add the exposure of the main foreign capital Romanian banks, the market has received sufficient liquidity.

The analysis of the monthly developments of the non-governmental credit, in real terms (having as a reference point 30 September 2008 – a moment when the effects of the international economic crisis started to be felt by the banking system in Romania) reveals

credit contraction starting with April 2009 (Chart no. 1).

From the perspective of denomination, trends were similar, but the amplitude of movements was different. Thus, the credit in lei has witnessed a relative decrease since May 2009, the phenomenon being gradually widespread. As regards the component in currency (expressed in lei), the values have maintained positive values during 2009 (a situation mainly occurring due to differences in the exchange rate), but have followed a strong descendent trend. The first months of 2010 have marked the start of the contraction of credit granted in foreign currency, which became positive again only in May 2010.

Chart no. 1. The Real Growing Rythm of the Non-governmental Credit

Source: BNR
*) fixed base 30.09.2009

Currency loans were about 60% of the total amount of non-governmental credit between January 2009 and March 2010, but their proportion witnessed a slight increase in the following months (Chart no. 2).

Chart no. 2. The Evolution of Non-governmental Credit according to the Denomination Currency

Source: BNR

In the context of the present economic crisis, according to the data of the National Bank of Romania the analysis of the credit sector of the counties in Romania indicates the fact that in just one year the Romanians' ability to pay their bank credits has considerably decreased. The increment of the arrears is caused by the clients' excessive crediting in relationship with the present income decrease.

Bankers have more and more problems with the non-performing loans, although they have reported reduced levels of delayed credit payment for each county between 2009 and 2010. There are multiple causes, both the surface ones such as salary decrease, job losses, interest increase and the case when clients have defrauded the banks, especially by using false papers. At the same time, if we take into consideration the fact that most of those who have arrears come from the private environment, the only sector that has known an adjustment at the beginning of the crisis, but we should not forget the state employees will have a diminished income and, thus, the non-performing loans will continue to increase.

At country level crediting has recorded a small increase between May 2009 and May 2010. In practice the credits granted for both individuals and legal persons was of 204.4 billion at the end of May 2010, with 2.2 percent more than in the similar period of 2009. The slight decrease is not the result of contrary tendencies between Bucharest-Ilfov Area and the other regions of the country. Thus, the capital and Ilfov county, the South-

West and the South region have been the only ones which registered an increase in crediting of 11.1%, 0.75% and 5.2% in the analyzed period. In all the other regions of the country the amount of loans was reduced, the largest contraction being recorded in the Center region and the South-East region, with a decrease of 3.5%. Other regions have also witnessed a significant decrease: West (-2%), North-East (-3%) or North-West (-1.92%).

The different rhythms of credit contraction have caused changes in the market share of the counties after the balance of granted loans. Bucharest-Ilfov preserves its leading position, with an amount of 38% of the total financing (77.54 billion) followed by the North-West region, with a financing balance at a less than third of the capital's balance (25.5 billion). The third place is occupied by two regions, Centre and North-East, which each had 9.4% of the total loans (19.2 billion). However, one can say that the North-East region has a slight advance, as the credit contraction has been lower.

Chart no. 3. The Credit Intensity on Regions

Source: BNR

Table no. 1. Counties with the Greatest Credit Arrears Intensity (%)

County	Intensity
Bihor	18,19
Bistrița-Năsăud	10,02
Galați	8,81
Suceava	8,49
Arad	8,23

Source: BNR

Table no. 2. Counties with the Smallest Credit Arrears Intensity (%)

County	Intensity
Gorj	3,39
Vâlcea	3,7
Tulcea	4,12
Vaslui	4,17
Prahova	4,17

Source: BNR

According to the destination of credits (for small operators, consumer and mortgage credits) one can observe that in some counties discrepancies among these segments emphasize differences in development among the administrative territorial units of the country. Nationally, the balance of the credits for legal persons registered a total of over 100 billion at the end of May 2010, increasing by 4.4% compared with the same period of 2009. Consumer loans were reduced by 2.7%, which is the segment in which most arrears are recorded, while through the "First House" program mortgage loans have increased by 13% up to 25.1 billion during a year.

In the total portfolio of loans the share of the outstanding and uncertain loans granted to the customers has increased from 0.32% to 1.5%, while in the total banking assets the intensity of delays in payment registered a growth from 0.29% to 1.01%. At the same time, the unadjusted exposure regarding loans and interest classified in the categories "uncertain" and "loss", including items out of the balance sheet, has increased from 5.95% to 13.52% by the end of 2010, in the context of aggravation of the financial situation of people and companies, but also in the context of increased volatility of the exchange rate of domestic currency.

After the National Bank of Romania has checked the commercial banks, it has also submitted a report which stipulates a series of measures that refer to:

- managing risks and establishing the thresholds at which risks are considered significant;
- reviewing policies regarding management of liquidity risk by improving the control strategies for liquidity crisis;
- reviewing credit policy by setting the limits of concentration on types of credit facilities;
- banning the grant of unsecured consumer loans;
- improving the process of monitoring and implementation of safeguards reevaluation;
- assessing the credit risk according to alternative scenarios for conditions of crisis;
- complying with the maximum admissible limits for large exposure.

The evolution of the banking system has proven that bank monitoring remains an activity required to ensure financial stability, and the future will bring even more challenges for the competent authorities. Consequently, the risks associated with the banking system are in a dynamic process, and the monitoring activity should be improved so as to counteract the functioning problems of the crediting institutions.

Building a Scoring Model for Bankruptcy Risk Prediction on Multiple Discriminant Analysis

Vintila Georgeta
Toroapa Maria Georgia
Academy of Economic Studies, Bucharest

georgia.toroapa@gmail.com

Abstract

The purpose of this paper is to use discriminant analysis to substantiate a score function effective in bankruptcy risk prediction of enterprises on Romanian economy example. For achieving discrimination between bankrupt and non-bankrupt in the scoring model we used relevant financial ratios related to activity, liquidity, leverage and profitability. The weighting coefficients established between independent variables and the objective function-score, are determined by using optimization, through a solver in Excel, with four financial ratios as input: return on revenue, cash-flow to debt ratio, debt to assets ratio, total debt payment period. Based on financial information submitted for 2009, the analysis was conducted on a sample of companies listed on the Bucharest Stock Exchang and achieved a success rate for the scoring model. The results in this article can be used to observe the evolution of a Romanian company over time, to make an idea about curent and future financial situation, and take, if necessary, corrective measures.

Key words: discriminant analysis, bankruptcy, prediction, financial ratios, score
J.E.L. classification: C38, G33, G17, G32, C52

1. Introduction

Numerous studies in the field of economic and financial analysis focus on bankruptcy prediction, but this does not necessarily suggest that analysts are fundamentally pessimistic persons, but rather can be argued

that bankruptcy is easier to define in terms of methodology than success.

Included by theorists in "professional applications of financial analysis " [1] or by practitioners in "other methods of financial analysis " [2], discriminant analysis can be also seen as a method belonging to the stage of maturity of financial analysis. The scoring is a method that involves internal and external diagnostic and requires risk interpretation for the investor, company's creditor, but also for the enterprise as a system in further activities. It is based on a value judgment development that combines a relevant group of financial ratios (or variables) [3].

Science-based models for bankruptcy prediction have been developed for the first time in U.S. in the '60s by W.H. Beaver [4] and E.I. Altman.

Beaver found that several indicators could successfully distinguish a sample of bankrupt companies to another one without financial difficulties, obtaining conclusive results for a period of up to five years before the onset of bankruptcy. Beaver examined financial ratios independently, without taking into account the existing links between them, resulting in a univariate or one-dimensional analysis. He has, however, the ground work for multivariate analysis, which was developed by Altman and by other economists, whose outcome is to develop a scoring model based on a combination of rates that distinguish the most risky businesses compared to the healthy ones.

E.I. Altman developed in 1968, a multivariate analysis of bankruptcy, combining five financial ratios in a single function, popularized as the score or Z-score model. Subsequently, this model was improved and published under the name

"Zeta Analysis", standing at the base of other bankruptcy prediction models, such as: Edmister model (1972), Diamond model (1976), Deakin model (1977), Koh and Killough model (1980), Fulmer model (1984), Koh model (1992).

The study of bankruptcy risk was restored in recent years, after an unprecedented number of bankruptcies recorded in most Western countries, as a result of the economic crisis that affected their economies. Thus, in 2001, U.S. companies that entered bankruptcy recorded debts totaling over \$ 240 billion, 39 of them each had debts exceeding \$ 1 billion.

Romania has expressed also an interest in obtaining a synthetic tool to forecast the risk of bankruptcy in banks and businesses. In this regard, should be mentioned: the B Score Function (1998), developed by Professor D. Băileşteanu from Timisoara University [4], Model I (1998) built by Professor Ivonicu (similar to B Score Function) [5], Model A (2002) Ion Anghel's outcome on the Romanian economy [6], [7].

Scoring models framed so far have the disadvantage that can be applied only in economies where the statistical study was conducted (or branch or sector analyzed), their use cannot be generalized territorially. Therewith, periods marked by economic instability change the correlations captured by the score function developed, which limits the temporal use of these models, requiring a re-enactment at regular intervals.

The purpose of this paper is to use discriminant analysis to substantiate a score function effective in bankruptcy risk prediction of enterprises on Romanian economy example. For achieving discrimination between bankrupt and non-bankrupt in the scoring model we used relevant financial ratios related to activity (stock rotation, receivable collection, debt payment, assets rotation), liquidity (current liquidity, quick liquidity), leverage (equity debt, cash-flow to debt, debt to total assets) and profitability (return on sales, return on assets, return on equity, return on revenue).

A first step in the scientific approach was to determine the weighting coefficients established between independent variables and the objective function-score, by using optimization, through a solver in Excel, with four financial ratios as input: return on

revenue (Net Profit/Revenue), cash-flow to debt ratio (Cash-flow/Total debt), debt to asset ratio (Total debt/Total assets), total debts payment period (Total debt/Turnover *360).

The research was conducted on a sample of 48 companies listed on the Bucharest Stock Exchange, out of which 27 were used to build the score function and 21 for a posterior analysis in determining the success rate of it. This analysis is based on financial information extracted from annual reports of companies (balance sheet, profit and loss, the Annexes to the financial statements) for the year 2009.

2. Developing a bankruptcy prediction model of Romanian companies on Multiple Discriminant Analysis (MDA)

In building the model, the following steps will be ran through :

(1) **Choose a sample** of companies that includes the two groups:

- Non-bankrupt (N-B) group : companies without financial problems.
- Bankrupt (B) group : bankrupt or ailing companies .

The sample considered in building the score function includes 27 Romanian companies both from public and private out of which 13 companies without financial problems and 14 companies are bankrupt or in difficulty (it was opened the insolvency proceeding) according to information posted on the Ministry of Finance website.

(2) **Compare**, based on a set of financial ratios likely to be significant, the two groups of companies, including indicators of activity, liquidity, leverage and profitability [9].

Detailed analysis of the sample allowed appraisal of the obvious differences between the two groups of enterprises. For this analysis there have been used the average and median of the financial ratios, most relevant being the median rates which eliminate unusual values encountered in some cases [10].

(3) **Select** the relevant ratios for the discrimination (Table 1).

Table 1: Average (AVG) and Median (MDN) of the financial ratios for the two groups non-bankrupt/bankrupt

Rate financiare	N-B		B	
	AVG	MDN	AVG	MDN
Current liquidity	4.49	1.82	0.67	0.65
Quick liquidity	4.01	1.35	0.46	0.36
Equity debt	0.16	0.01	-0.19	0.03
Cash-flow to debt	1.23	0.00	-0.01	0.00
Debt to asset	29%	30%	91%	83%
Stock rotation (days)	39	45	73	71
Receivable collection (days)	137	107	124	89
Total debt payment (days)	161	127	709	466
Supplier payment (days)	44	28	127	115
Asset rotation	0.71	0.63	0.67	0.61
Return on sales	16%	9%	-30%	-18%
Return on equity	9%	8%	-132%	-32%
Return on asset	10%	10%	-82%	-11%
Return on revenue	14%	6%	-35%	-21%

(Own calculations)

Following the selection step we kept the following four financial variables: return on revenue, cash-flow to debt, debt to asset and total debt payment period.

$$X_1 = \text{Net Profit} / \text{Total revenue}$$

$$X_2 = \text{Cash-flow} / \text{Total debt}$$

$$X_3 = \text{Total debt} / \text{Total assets}$$

$$X_4 = (\text{Total debt} / \text{Turnover}) * 360$$

(4) **Develop through discriminant analysis technique** a linear combination Z of relevant ratios (Xi).

The weighting coefficients established between independent variables and the objective function-score, were determined by

using optimization, through a solver in Excel, with four financial ratios as input: return on revenue, cash-flow to debt ratio, debt to asset ratio, total debt payment period.

Therefore, we assume two parameters **a** and **b** which are determined by the following relations:

• To optimize variables through maximum :

$$a = 1 / (X_{\max} - X_{\min})$$

$$b = -X_{\min} / (X_{\max} - X_{\min})$$

• To optimize variables through minimum :

$$a = 1 / (X_{\min} - X_{\max})$$

$$b = -X_{\max} / (X_{\min} - X_{\max})$$

where:

X_{\min} = minimum value of the variable (bankruptcy);

X_{\max} = variable's value when bankruptcy risk is minimal.

Table 2: Weighting coefficients for the Z function

Variable	Value		a	b
	Min	Max		
X_1	-1,65	0,77	0,4136	0,6830
X_2	-4,13	20,02	0,0414	0,1709
X_3	0,01	1,79	-0,5605	1,0038
X_4	23,04	2256,38	-0,0004	1,0103

(Own calculations)

The function developed after the optimization process (Table 2) is:

$$Z = 0,6830 * X_1 + 0,1709 * X_2 - 0,5605 * X_3 - 0,0004 * X_4 + 1,414$$

(5) **Choose an inflexion point (or points)** to perform predictive classification of enterprises in the two groups.

After setting the Z score for each enterprise and ordering information ascending according to it, results a status of all companies in the sample. The inflexion point is chosen in order to minimize the error rate and has assigned an uncertainty range.

The inflexion point that minimizes the error rate is **Z=1,0113**, with an uncertainty range between **1,01 and 1,16**.

(6) **A priori analysis of the success rate** for Z score by comparing the predictive classification (II) with companies known condition (I) in the sample. We recall that this is a priori success rate because it is based on a sample test that led to the score function development.

Table 3 : A priori analysis of the success rate

Enterprise	I	Z Score	II	Rtg
1	B	-1,1986	B	1
2	B	-0,5260	B	1
3	B	-0,3881	B	1
4	B	-0,1044	B	1
5	B	0,1354	B	1
6	B	0,5406	B	1
7	B	0,5447	B	1
8	B	0,5731	B	1
9	N-B	0,6925	B	0
10	B	0,7157	B	1
11	B	0,7230	B	1
12	N-B	0,8695	B	0
13	B	0,8824	B	1
14	B	0,8964	B	1
15	B	0,9206	B	1
16	N-B	1,0113	N-B	1
17	N-B	1,0599	N-B	1
18	N-B	1,0943	N-B	1
19	B	1,1008	N-B	0
20	N-B	1,1662	N-B	1
21	N-B	1,2008	N-B	1
22	N-B	1,2814	N-B	1
23	N-B	1,3426	N-B	1
24	N-B	1,4050	N-B	1
25	N-B	1,4508	N-B	1
26	N-B	1,7107	N-B	1
27	N-B	5,0832	N-B	1
Success rate without uncertainty range				88,9 %
Success rate with uncertainty range				91,3 %

(Own calculations)

Table 4: A priori analysis of the error rate for the model

Classification	Actual	Prediction
B	14	15
N-B	13	12
Total	27	27
Error	Error No.	Error %
Type I	1	7,1%
Type II	2	15,4%
Total	3	11,1%

(Own calculations)

We noted that **an inflexion point equal to 1,0113** leads to a **success rate of 88,9%** (24 correct classifications out of 27) and for two inflexion points ($Z = \text{minimum } 1,01$ and $Z = \text{maximum } 1,16$), which means considering a range of uncertainty between these two points, the **success rate** of the model is **91,3%** (21 correct classifications out of 23 companies located outside the uncertainty range) (Table 3).

A priori predictive analysis of the Z function showed that Type I error (bankrupt companies classified as non-bankrupt) is 7,1% and Type II error (non-bankrupt companies classified as bankrupt) shows a failure rate of 15,4% (Table 4). Z score value scale and range of uncertainty are summarized in the following table (Table 5):

Table 5 : Z Score Range

Z Score	Type	Remarks
5,0832	Non-bankruptcy	Upper limit
1,1662	Non-bankruptcy	
.....	Uncertainty range	
0,9206	Bankruptcy	
-1,1986	Bankruptcy	Lower limit

(Own calculations)

As a conclusion, the Z score function remains:

$$Z = 0,6830 * X_1 + 0,1709 * X_2 - 0,5605 * X_3 - 0,004 * X_4 + 1,414$$

The assessment is based on the following (Table 6):

Table 6: Risk assessment in Z model

Z Range	Assessment
$Z < 1,01$	Bankruptcy / Failure
$1,01 < Z < 1,16$	Uncertainty range
$Z > 1,16$	Non-bankruptcy

(7) **A posteriori analysis of the success rate** for the Z score by analyzing the degree of relevance for another sample of 21 firms.

Considering another sample of 21 companies, separated also in the two groups B and N-B, classification that results from financial statements listed on the Bucharest Stock Exchange and the additional

information provided by ministries for the year 2009, we analyze prediction accuracy for the Z model. The sample includes as mentioned before, 21 companies, 10 belonging to the N-B group and the other 11 enterprises belonging to group B. The enterprises from the testing sample are similar in size and sectors as those from the initial sample.

Table 7 : A posteriori analysis of the success rate

Enterprise	I	Z Score	II	Rtg
1	B	- 0,669 2	B	1
2	B	0,584 1	B	1
3	B	0,659 1	B	1
4	B	0,672 4	B	1
5	B	0,679 7	B	1
6	B	0,703 9	B	1
7	B	0,710 0	B	1
8	B	0,846 2	B	1
9	B	0,930 8	B	1
10	B	0,937 9	B	1
11	B	1,003 0	B	1
12	N-B	1,058 4	N-B	1
13	N-B	1,068 4	N-B	1
14	B	1,115 1	N-B	0
15	N-B	1,119 9	N-B	1
16	N-B	1,156 7	N-B	1
17	N-B	1,170 8	N-B	1
18	N-B	1,222 1	N-B	1
19	N-	1,249	N-	1

	B	8	B	
20	N-B	1,277 9	N-B	1
21	N-B	1,284 0	N-B	1
Success rate without uncertainty range				95,2%
Success rate with uncertainty range				100%

(Own calculation)

Under these conditions we observe that the **success rate of prediction without the uncertainty range** is higher than a priori, reaching **95,2% and the rate of success with the zone of uncertainty is 100%** (Table 7). This allows to conclude that the Z score is effective also on the new test sample of companies (withholding limits considered in building the model) (Table8).

Table 8 : Comparative analysis a priori vs. a posteriori error rate in Z model

Type	Eşantion initial		Esantion testare	
	Actual	Prediction	Actual	Prediction
B	14	15	12	11
N-B	13	12	9	10
Total	27	27	21	21

Error	Error No.	Error %	Error No.	Error %
Type I	1	7,1%	1	8,3%
Type II	2	15,4%	0	0
Total	3	11,1%	1	4,8 %

(Own calculations)

3. Conclusions

Given the current economic situation, trying to build a bankruptcy prediction function score for Romanian companies is a real challenge. Although useful and necessary for users who are interested in the financial health of a company, bankruptcy prediction model shows besides obvious advantages, some limitations such as:

- The sample considered for Z function is limited, number of companies taken into account both for the a priori and a posteriori analysis is relatively small, but the principle and methodology of the research are correct and can be extended to much larger samples.

- Lack of a longer period for analysis before bankruptcy (Z model is based on an analysis period of one year) may reduce the predictive ability compared to the current situation, as the Romanian economy is not in a stable economic period.

As main advantages of the Z model we mention :

- The Z score function developed is a simple function (with only four financial variables) that manages a priori prediction success rate of about 91,3% and a posteriori success rate of 100% with uncertainty range.

- General applicability of the model for the Romanian economy, while the sample that led to the function development included companies from different industries (manufacturing, services).

- The framed model was based on researches developed both domestically and internationally, in the specific field of discriminant analysis and prediction of bankruptcy.

- The sample and separation of the two groups (bankrupt and non-bankrupt) was not based solely on the legal declaration of bankruptcy, but included a more general component specific to bankrupt companies (default)

Discriminant analysis as relevant method in the arsenal of economic and financial analysis tools will become a necessity in the next period, for understanding and applying the economic reality in predicting specific questions of interest to users of financial and economic information. This may prove effective for: further research bankruptcy prediction in companies with specific application to economic sectors or small and medium enterprises; judging companies operational activity by auditors and accountants; using score functions to provide information to investors concerned about finding the most profitable investments, or solutions for their portfolio in order to earn an optimal overall return-risk per share; using discriminant analysis in the macroeconomics,

in areas such as analysis and prediction of success vs. failure of specific economic policies on the development of disadvantaged areas; implementing economic programs for the development of certain industries or sectors.

Convergence of Social Insurance Public System with Private Pension System in Romania

Vîrlănuță Florina
"Dunarea de Jos" University of Galati
florinaoana27@yahoo.com

Abstract

Romania has a long tradition as regards social security, which is a modern system, since the early twentieth century. Although they are based on increasing the contribution of each citizen, in proportion to the amount being fixed it, PAYG pension system implies certain redistribution based on the principle of social solidarity and between categories of pensioners. In this paper we have proposed an analysis of the current pension system, considering its two components, mandatory and optional. We also conducted an analysis of key financial guarantees private pension system.

Key words: insurance system, financial guaranties, social security

J.E.L. classification: G22, G23

1. Introduction

Until a few years ago, every international meeting pension and insurance is discussed and debated the same topic: the alternative to a public pension system is a system with one or more components based on accumulation, mandatory or optional, privately managed. It further believes that the public pension system is the solution for paying pensions to the current system and multi-component system, of which at least two are based on accumulation, is presented as a possible solution, not the only solution, the current issue facing all countries population ages.

In this international context, Romania entered the two components of the pension system. The problem appears in terms limits and if you have created private pension rules that constrain or better pension schemes that they operate freely, allowing market mechanisms to promote the companies

providing services tailored to the business. Otherwise we have designed the constraints and opportunities than in developed countries because there are major differences in level of development, even in retirement, compared to developing countries, including Romania, consumers with little experience in investing.

2. Social insurance public system

State pension system in Romania is the least financially sustainable in the long term the entire region of Central and Eastern Europe, which means that it is most likely either to become an unbearable burden for the state budget or to collapse. The main problem for Ro-wrath against other countries in the region is the explosive growth of state spending on pensions as a share of GDP by 2050. Thus, while in Romania the figure will climb from 8.4% to 14.8% of GDP during 2010-2050, in Hungary the trend will be 11.3% -13.2% of GDP, while in Bulgaria will be 9.1% -10.8% of GDP. In 2050, if the S & P estimates will prove to be accurate, Romania will spend the most on pensions as a share of the economy of all countries in Central and Eastern European region. Estimates relate only to the state pension system, without taking into account private pensions. [8]

Pensions Act marked the beginning of pension reform in Romania, making the transition to a complex system of social security and pension reforms involved fundamental, in addition to designing a new system, policy, legislation and institutional framework necessary.

It took into account long-term demographic analysis; it seems that future pension situation will become even more difficult due to aging.

The public pension system in Romania is granted the following types of pension:

- Old-age pension
- Early Retirement
- Partial Early Retirement
- Disability pension
- Survivors' pension

Although they are based on increasing the contribution of each citizen, in proportion to the amount being fixed it, public pension system implies certain redistribution based on the principle of social solidarity and between categories of pensioners.[2]

Due to this redistribution (fixing a ceiling on the maximum pension, the value of a minimum pension of a minimum period of contribution) certain taxpayers are disadvantaged and many of them would help if he had not obligated.

Forecast in 2050 Romania's population will reach about 19.4 million, 3 million less than in 2000. Population structure will change, increasing significantly the number of people over 60 years, so that the ratio between the population between 45 and 60 years will reach about 51%. In other words, about half of the population over 45 years will be made up of retirees. [3]

In this regard we consider absolutely necessary to support private pension insurance system.

In context of the current economic crisis, the public pension system in Romania is unsustainable, and private pensions are an alternative for the future.

In the following we highlight the role of the private pension system, its evolution and financial guarantees.

3. Alternative pension and financial guaranties

Pension reform through the creation of occupational and private pension funds is the only viable solution for the countries of Central and Eastern Europe, experiencing, as I said, with a pronounced population aging. The usual tests often meet the particular characteristics of pension systems, regarded as typical scheme, without taking into account the fact that they, in interaction with other factors, can result in a totally different system configurations.

The purpose of private pension funds (mandatory) is to provide a pension that supplements the pension paid by the public system, based on the collection and the investment by private specializes companies in the interest of participants, part of the contribution of individual insurance. By collecting and investing by private and specialized companies of one part of the individual social insurance contribution.

Privately managed pensions, Pillar II or mandatory private pensions, as they are known by the general public, are characterized by directing a share of the personal social security contributions, which is paid monthly in the public system to private pension funds. Contributions are paid as long as that person has the status of taxpayer in the public pension system. Once entered into this mechanism, as required by law, there isn't the possibility of leaving the private pension system, but it is allowed the transfer between funds.

It is noted that the investments consisted by the assets of these funds are regulated, supervised and carried out according to the risk class of each fund, in efficient and prudential conditions.

The right to the privately managed pension opens at the retirement moment, according to retirement age in the public system.

Pension payment will be made by a pension provider and the pension is based on actuarial calculations and net personal assets, according to the accumulated sum of contributions and their investment by pension fund administrator.

If individuals whose net personal assets, at the date of opening the right to pension, are too small to receive a private pension and the disability pensioners for conditions that do not allow the resumption of work, money can reach the recipient as a single payment.

According by law, managers are required to contribute to a Guarantee Fund and the law establishes other security features for Pillar II system: separation of assets from the fund manager, the technical provisions, the minimum rate of return, ensuring net contributions

Also, asset depository and the auditor acts as a safety belt on the pension fund assets.

Persons aged 35 and 45 years were also able to join, but they weren't obliged to do so. Subsequently the original accession, persons required to sign and did not choose a pension fund during that period were randomized.

Currently, each employee pays an insurance contribution system related public pension contribution equivalent to 10.5% of gross salary for each taxpayer. [3]

Contributing to a pension fund does not create financial burdens for participants, but some individual contribution due to the public pension system. Currently, 2.5% share is transferred (2010) and will reach 6% in 2016. Opting for a private pension, a part of this contribution will be redirected to individual account opened on behalf of each participant in private pension fund chosen.

If we speak of Pillar II system, the participant is entitled to a pension on retirement conditions for old-age public pension system. The total amount due for private pension can not be less than the amount of contributions paid, reduced by the penalty of transfer and legal fees.

Same the case with disability for conditions that do not allow the resumption of activity, if the net personal assets is not sufficient to grant a minimum pension as a result of reduced period of contribution.

The beneficiaries' of private pension rights are the same as those of the participants in that pension funds. Beneficiary is entitled, as appropriate, to the aggregation of accounts from one pension fund, if he participates in another pension fund or to pay only if he isn't a participant.

In case of changing job, home or residence in another country, EU membership or the European Economic Space, the participant and beneficiary retains the right to pension gained in private pension schemes pension in Romania and this is paid in that state, as the left amount after subtracting all fees and expenses related to payment.

After retirement, the participant may choose the private pension provider. The amount of these benefits will be based on actuarial calculations and net personal assets located in the participant's account. The pension's size depends on the pension contributions paid over the time and also depends on the yields of the fund manager on which the participant has contributed.

The main financial guarantees private pension system is reserve fund and private pension guarantee fund.

4. Evolution of the private pensions market in Romania

The risk level and performance indexes should constitute the main criterion when choosing a private administrated pensions fund, whether being a first adhesion to this system or a transfer from a less performing fund to some other, more efficiently managed. Nevertheless, guided according to the performance, we shouldn't be influenced by the fluctuations of the financial markets, now and then. Therefore, performance indexes in private pensions system are relevant only calculated for long periods of time, that meaning several years.

When choosing a pensions fund, we have to take into account the risk type, the administrative costs, as well as the experience and the renown of the company managing the fund.

It has to be pointed out it's illegal for an employer to impose its employees the choice of a pensions fund.

Should the manager of the pensions fund have no past on the market in Romania, the adhering decision may be judged upon the fame and the prestige of the society, as well as by the investment strategy, based on the prospect of the pension scheme.

After a two-year function of a private administrated pension's fund, the eligible persons could select the fund on the profitableness basis. This criterion relies on the following: the administrator of a pension's fund, receiving contributions for at least 24 months, should calculate, last working day of every quarter, the fund's profitableness quota for the last 24 months.

Also, the operating costs of the fund can be used as a supplementary distinction marker, as long as less expense ensures more money in the participants' accounts. Going on with the tendency noticed from the start, the Romanian private pension's funds recorded a slight increment, keeping up the monthly slow pace of the final of 2009.

Thus, as of February 2010, 4.971.803 persons participated in the private administrated pensions funds- 2nd Pillar,

growing with 0.7% compared to January 2010. The value of the net assets recorded by the private administrated pensions funds was of 2725.8 million RON (664 million Euros), growing with 7.4% compared to January 2010. [3]

The funds of optional pensions- 3rd Pillar recorded a slight increment, too. So that, in February 2010, the number of participants was of 190327 persons, growing with 1% compared to January 2010 and net assets amount was of 228.3 million RON (56 million Euros), increasing with 6% compared to January 2010, respectively. [5]

5. Conclusions

The main problem facing the public pension system in Romania is insufficient funds. This is due mainly to the ever decreasing number of active people.

Pensions are the most important social insurance benefits paid in the public system of social insurance.

In the context of a growing phenomenon exacerbated by an aging population puts increasing pressure from growing on the mechanisms of social protection, management of public pension system was a challenge for all countries, including the economically developed security systems social tradition.

Thus, both at European and national level, reform of these systems is necessary to ensure sustainability of public pension schemes to increase pensioners' quality of life more akin to that of the active period, by introducing and implementing the security system of two social components, other optional compulsory one, both managed by private companies. As a conclusion of this analysis, we consider both timely private pensions pillar II and pillar III. It is very important, but efficient use of funds set up, their rates of return.

So we recommend the development of private pension systems as an alternative to the public pension system.

Dimensions of Electronic Commerce in Romania

Vlad Cătălina

Manea Natalia

„Spiru Haret” University

vld_catalina@yahoo.com

nataliamanea@yahoo.com

Abstract

Since its appearance, electronic commerce has had a significant impact primarily on thinking and business performance. Also, electronic commerce, had a strong influence on the global economy by destroying the barriers of time and space, providing both traders and consumers to interact and engage in conducting commercial transactions, regardless of their location. For some companies, electronic commerce means any financial transactions using computer technology. For others, the “e-commerce” term covers the whole sales, including marketing and selling itself.

Key words: e-commerce, virtual market, e-shop, e-mall, e-procurement

J.E.L. classification: M00

1. Introduction

In the emerging global economy, e-commerce has increasingly become a necessary component of business strategy and a strong catalyst for economic development. The integration of information and communications technology in business has revolutionized relationships within organizations and those between and among organizations and individuals. Specifically, the use of information and communications technology in business has enhanced productivity, encouraged greater customer participation and enabled mass customization, besides reducing costs.

2. How we define e-commerce?

Electronic commerce can be defined as modern technology to do business, which addresses the needs of organizations, traders and consumers, aimed at reducing transaction costs, while improving quality of goods and services and increase delivery speed.

E-commerce means the distribution, marketing, sale, or delivery of goods or services electronically. Option of electronic commerce involves the development and implementation of information architecture based on inter-communication and information technologies and especially Internet technology of achievement in commercial processes. Electronic commerce is quickly becoming a very important tool for enterprises. E-commerce offers to the seller a less expansive means of expansion and to the customer offers easy access to a wide range of products and services. Comparative studies, traditional commerce versus e-commerce, show that electronic commerce gives to the companies the option of a more flexible relationship with business partners.

We remember in the following key concepts of electronic commerce:

Online shop (e-shop) is managed by a company for marketing and selling their products or services. To talk about an electronic store, there must be at least the catalog of products (services), commercial and technical descriptions for each position in the catalog.

Universal electronic store (e-mall) is a collection of stores, united under a common umbrella, for example, a well known brand. Typically, electronic department store definitely accepts common payment method.

Electronic Procurement (e-procurement) is based on the fact that, generally, to procure necessary goods and services, public authorities and large companies use auctions.

A third market (3rd party market place): in this case is appealed to an "interface" user's product catalog, user interface that belong to a third party (generally an Internet service provider or bank. This single interface to several manufacturers of goods became known buyers, being attached to frequently accessed information channels (e.g.: one-button access from the most popular electronic journal). Virtual communities-biggest value of a virtual community it's given by his members (customers or partners), which adds its own information base over a medium supplied by the company. Each member may offer to sell or make requests to purchase products or services. Membership of a virtual community requires a fee. Such providers are specialized in specific functions, for example, providing logistics, electronic payment or expertise in production and stocks management. Payment of such service providers is based on a quota or percentage rates.

Collaboration platforms include a set of tools and information medium need for the collaboration between departments. They may address specific functions, such as, for example, conception or design in cooperation. Gains will come from management platform (member fee or fee per use) and sales of specialized tools (for design, workflow and document management). Information brokerage and other services. There are a lot of services that add value to the mass of information available in open networks or from integrated systems, such as providing customers classified catalogs on your profile, selling business opportunities, investment advice, consulting in specialized areas. A special category is the reliable services provided by certification authorities or electronic notaries^[1]

3. Advantages and disadvantages of e-commerce

E-commerce presents a number of advantages and disadvantages, analyzed in terms of the dealer, on the one hand, and on the other side of the buyer's perspective.

Compared to the merchants, some of the benefits of electronic commerce refer to: contact with customers, both day and night,

all weekdays, and the costs are very low; facilitate the entry to international markets, the possibility of access to goods and services providers worldwide, thus expanding business in foreign markets; easy access to market research, studies on the broader issue that involves market and its components, namely the population's demand, the supply of goods, consumption and its futures particularities, price, quality, delivery time, content products and their components; creating the condition for direct marketing practice (one to one) because, unlike humans, computers can hold much more information about the customer, since their names and personal data, continuing with their preferences, being able to adapt the offer and the presentation of products by each customer's profile; the bidding for a variety of products and services appearing in this auction sites, joint purchasers and barter; closer and easier integration of local and foreign suppliers in the supply chain; increased revenue through partnerships of small traders to larger businesses^[2]

In relation to buyers, e-commerce also presents a number of advantages: permanent availability to all those interested in, independent availability of such a program, this means a big advantage for the customers who have the opportunity to make purchases both day and night, when they have time and funds needed; convenience; free access to information and various products.

Electronic commerce involves however a number of disadvantages, both regard to traders and buyers. Thus, relative to the retailers, the disadvantages are focused on: possibility of fraud, because in the absence of a direct contact, a trader client can cheat on his identity or his real possibilities of payment; ensuring data security. Connecting to a public network where anyone can access, more or less authorized to confidential data on your local network really raises questions in the presence of risks that did not exist for traditional trade. Related to the buyers, the e-commerce disadvantages refer to: security, privacy, lack of human contact, access to technology. Potential buyers fear that, through the Internet, merchants or a bad person can collect very detailed information about them without even realizing. Unfortunately, these fears are the result of exaggeration, especially in the West, is very

fashionable the conspiracy theory.

In terms of electronic commerce over the Internet, there are a number of operational advantages as a result of Internet using in business: small percentage of errors; saving time; reducing costs due to the use of electronic databases; creating new market segments and sales; increasing sales; a fast entry into the markets; higher speed the buying process.

4. Romania's e-commerce

Appeared in Romania at the end of 1999 and knowing a very important point of growth so far, electronic commerce is near the beginning stage of maturation. Even if it register now a very large increase in electronic commerce, few e-stores will survive this transition period, and in 3-4 years we can speak of a stable e-commerce market. Open an electronic store can help develop business or become a real problem. Success or failure depends on establishing clear targets proposed to open the store and careful planning of how e-commerce business will be integrated current business strategy and daily operations. Although customers are afraid that the safety offered by electronic commerce, it is certain that the number of customer e-shops and companies that adopt e-commerce system is increasing. Many Internet service providers purchase this online system to induce an added confidence and consideration.^[3]

5. The main developers of e-commerce solutions

IBM Corporation- develops the Web Sphere server. In 2001, IBM launches Web-Sphere Commerce Suite Pro5.1, which is an e-commerce solution based on Java.

The largest company in the world, Microsoft Corporation, launched in February 2000 Windows 2000 operating system, a version of Windows NT, after about five years of development^[4] Windows 2000 was created to serve as a platform through which companies, including e-commerce to be able to conduct business. In an effort to compete with IBM's Web Sphere server, Microsoft is launching in December of that year, the BizTalk service. In view of the writer John

Fontana Network World, "BizTalk is one of the basic parts of Microsoft's attempt to impose its Windows operating system and applications as a platform for the Internet."

The nearest rival of Microsoft Corporation in software is Oracle Corporation, founded in 1977.

The company competes with Microsoft and in e-commerce solutions. Oracle has become a leading provider of e-commerce in 1998 when launching Oracle 8i, a well-known version of their database software, integrated with web services.^[5]

In Romania the situation is far from the Americans, for example, which give special attention to this type of shopping. Tributary to the Romans are still stereotypes which bought the property should be palpated, measured and returned on all sides. In recent years, but a new social class appeared, the people who work in the private sector have a particular style of life and extensive use of Internet. Online shopping, with their obvious advantages, starting to become commonplace for them. A proof of the maturity of electronic commerce in Romania is present in the top 10 of two sites shopmania.ro price.ro and offering a comparison of the products offered by various online stores. These systems are very popular in developed countries and represents proof of maturity, from those who buy online. Another important aspect is the presence of the top ten e-commerce sites not less than four online stores that sell IT products, electronics, mobile and / or appliances. Even five sites and if we consider dol.ro (which offers such products). In conclusion, we see that online stores offer the largest IT products in cyberspace Romanian search. This confirms us that in Romania Information Technology plays an important and those who have a computer are the first to call with more confidence in these services. Position in Top 10 librarie.net site, we confirm that the Internet are in high demand books. The explanation is simple: in Romania, the most developed system of payment is cash.

Clearly, books, CDs, DVDs fit best in this trade. Detached leader, at least in this time of year, is the site okazii.ro. The website Net Bridge Investments was launched in April 2000, the basic idea consists in providing an environment where it is possible that buying and selling at the best price for various

items. In the top online stores in Romania, we find culinar.ro site through which we find at home food delivery services, caterers. If we are too busy or not very comfortable, we can call one of the companies present on site to help us to purchase products that we need.

Turning to the disadvantages of electronic commerce (degree of uncertainty, infrastructure, attitude and ignorance) to Romanian buyers, accustomed to traditional commerce, we enumerate several obstacles to overcome: buyers can not touch / test the products, presenting items in stores counting very much; there was a salesman who can make recommendations and answer questions, even though many online stores offer online support; have implemented a system of delivery and reception of money, be promoted to potential buyers shop. Most major online stores in Romania have understood these obstacles and to a large extent have tried, successfully, to overcome them.

According to an initial survey in 2006, then resumed in 2008-2009, continued in 2010, which relates to the subject from the customers, it is interesting to observe several developments: the percentage of people who would buy more frequently on the Internet if they receive special offers discount: 8% in 2006 to 18% in 2009-2010; decreased the percentage of those who want faster delivery: from 25% in 2006 to 6% in 2009-2010. This does not mean that delivery is much faster now, but that those who order online are not so sensitive to delays, but more on price. Paradoxes considering the current economic situation in Romania, the low number of those who say that a better financial situation and would encourage more often ordering: from 21% to 15% above the same period analyzed. "As e-commerce sales volume in Romanian, the annual total is around 250 million euros, but we expect to grow rapidly in coming years due to changes in consumer purchasing preferences, which significantly migrate to trade online ", said Marius Ghenea, president of the Romanian Association of Online Shops (ARMO). And the forecast for this year are encouraging. This market will grow on average by 15-20% in 2011, says representative ARMO^[6]

6. Conclusions

The conclusion arising from this study in terms of online shopping in Romania: 49% of those surveyed say they buy online to save time, not saving money; delivery time are interested in getting less than in previous years; The main incentives that would convince you to buy more often low prices and discounts. Thus, we can say that online prices in Romania are still large and the main advantage of a command economy of time is necessary.

Present Issues of Global Economy

Vlad Costică

„Ovidius” University of Constanța
euro_financial_consulting@yahoo.com

Mitea Neluța

“Andrei Șaguna” University Constanța
nelutamitea@yahoo.com

Abstract

The present financial crisis is the result of the „cheap money” philosophy put in practice at the beginning of the millennium by the national American Reserve. In a globalised world both the benefits as well as the risks are rapidly transmitted on a large range causing either positive or negative effects. The most important constant fact is that real risks for the world economy have been identified in real time but they, also, have been, for various reasons, ignored. As a consequence, it appeared the most severe world crisis and it is estimated that its effects will be present for a long period of time. Paradoxically, ostensibly, the most serious effects appeared in the most developed economies as a consequence of interdependence ties of the financial markets with the American market. The second part is about the structural crisis from Romania and the conclusion is that no matter of the international context, the crisis would have manifested itself. The analysis of the crisis evidenced the necessity of a radical reorganization for the global financial system and for Romania the reorganization on strict scientific bases of the whole social-economical environment. The next challenge is the permanent adjustment of the equilibrium between state regulations and free initiative.

Key words: Financial crisis; Structural crisis; Subprime credits; Cheap money; Adjustment mechanism.

J.E.L. classification: F30, G01

1. Causes of the last financial crisis

An unequivocal answer about the way we reached this economic-financial crisis is difficult to give. After 2003, when the recession from the USA ended, everybody believed that a stable business environment was created, with *selfmaintainance tendency*, with an endless economical growth. What happened on the so-called *Black Tuesday* on October 29, 1929, repeated? In order to give an explanation is necessary a summing up of the capitalist development philosophy. The globalization had positive effects because of the liberalization of the world trade, the diminuation to the disappearance of communication costs, the expansion of the management request, etc. The globalization process also imposed misregulations of the financial markets so that both the profitability and the associated risks can be transferred rapidly at a global level. The general optimism was justifiable by the fact that each time the consumer society found the necessary resources to overcome the critical situations. Starting with the 80's, the introduction on a large scale of the information technology, first in the United States and then in the other developed economies, created the premises of a growth of labour productiveness in a superior rhythm for the wage expenses. This situation permitted the accumulation of capitals for investments and for the growth of the consumption segment. The benefic effects of the information technology introduction ended around the year 2000 and then it was necessary to find another factor to animate the economical growth. To this point it is also necessary to remember a psychological factor with important subsequent implications. The fall of the communism inducted the idea

that only a capitalist society is viable and, as a consequence, a relaxed attitude towards confronting the risks appeared. Technologically, a growth factor of the productiveness such as the information technology was no longer available and, under these circumstances, a financial origin factor was approached, that is "cheap money", this factor allowed an easy access to credits for companies and a part of the population that previously were excluded by the imposed conditions of the banks. Even if in developed economies was already present, as we have previously mentioned, a riskseek attitude, the well-known financial institutions analysed with seriousness the economical-financial evolution and identified the possible risks as well as their probable consequences. The O.E.C.D. president pointed that „The global economy is rising, but it also has to face the risk of economic disbalance and the rapid growth of the interests because of the too sizable public deficit". A study of Global Insight, showed that a greater impact than that of the increased price of oil, it could have been the *collapse of the real estate market* in the developed contries that were facing the overevaluated prices phenomenon and could have been followed in a short period of time by their brutal fall, which it really happened. The amplitude of the effects of real estate market collapse was given by the fact that the real estate properties represented 60% of the total real assets in the world. Global Insight appreciated that another major risk was coming from the companies unable to create more *working places*.

As noticed, although the risks have been identified correctly, no measures were taken neither at the market level nor at the level of the authorities to stop or to diminish the manifestation of the risks. The issue can be considered even backwards. Without the "cheap money" policy the world developing rhythm would have been the same? The growth of the world's Gross Domestic Product calculated according to the parity of the purchasing power was of 4,9% in 2005 and of 5,3% in 2006. This growth was the most accelerated for the last 20 years. To be noticed that in the same period, while the developed contries registered a modest rhythm of development to 2,5% (USA – 2,2%; Germany – 1,4%, etc.), countries that

were developing situated themselves over the average (China-9,8%; Czech Republic – 5%; Romania – 6,5%; etc.). The conclusion is that the main winners of the new financial strategy were the emergent economies, but one must not forget that the greater risks were to be faced by the same economies. The year 2008, marked a turning point in the history of the world economy and trade. The growth of the world economy slowed down suddenly until the end of 2008 at the same time with the aggravation of the world financial crisis. The year 2009 meant the decrease of the world's GDP with 2,7%, after a long period of growth. The first signs of the crisis registered in the autumn of 2006 on the New York Stock Exchange and exacerbated in the following year leading to a falldown of the world economies and financial markets. The multitude of causes that led mankind in the crisis can be found both in the speculative behaviour of the economic agents, mainly, but also in the behaviour of the market reglementation institutions. The economic science supported by the practice shows that a system crisis can be provoked by a *monetary surplus* over the needs of an economy in order to assure the normal merchandise and service circulation. The monetary surplus is dued to the unjustified economic reduction of the interest rate, phenomenon that stimulates the expansion of the credit. Without a fair management, the inflationary policy of the state generates delusive profits and feeds the speculative phrensy which, in the end, disintegrates under the burden of its inconsistency. The main factor, determinant of the crisis is the inflationary policy from the beginning of the 2000 years. The monetary policy of the US Federal Reserve System (FRS) was to stimulate the internal economic growth in a rapid rhythm and on a long term. The aim of money issue and a policy of lower interests was to decrease the financing costs for companies, risking an accentuate growth of the inflation. The nominal interest rate fell from 6,25% at the beginning of the year 2000 to 1,75% at its end. It continued to decrease reaching a record level of 1% in 2003, at this level remained for a year. In the context of increasing prices, the real rate was negative for 2 and a half years, which meant that the banks were paid to take money from the US FRS, money that was spent in the economy

considering other stimulents and political pressures that influence decisions. The USA example was followed by the Bank of Japan which offered to the commercial banks money with a zero nominal interest and the Central European Bank reduced the interest rate to about 2%, level to which was maintained for almost 4 years. A great deal of money from the central banks was invested in their own economies. The best example is the real estate boom from the USA, but such phenomena manifested in all the countries in which existed the monetary conditions for real estate speculation. The other part of the money was used abroad as direct and capital foreign investements, with great risks at times. The occidental financial groups greatly attracted resourses on a short term and at a lower price from the international financial market using them to sponsor the growth of their subsidiaries' turnover from the emergent economies. A great part of these capital flows were invested in other real estates assets, investments little liquid and risky, but very profitable as long as the market continuous to grow. This phenomenon registered in Eastern Europe, too, as well as in Romania.

According to the statistics, from the mid-2007, when the *subprime* panic started, the dynamic of the deposits stopped keeping up with the credit evolution, the bank sector started to accumulate rapidly and vertiginously debts of about 250 billion of dollars, a great part of them on a short term. It is estimated that 90% of these debts are of the European banks. In the following period the non-performing credits increased as volume, the worst appreciations presenting a figure of 5000 billiards of dollars. Every state considered their economical development and the immediate policy interests. The former had a high level of subjectivity which is mostly contradictory with the objectivity of the economic action. With the abundant money issue, a state assumes the so-called *too big to fail policy*, that changes the bankers and investors behavior, mainly, the attitude towards risk. Printing uncovered money, in the real economy were overcome the local crisis from the years 2000. Such a behavior of the state, also known as the „*moral hazard*” determines the exit from the economic rational patterns, investors being sure that the state will take over the possible

losses. In such conditions, the most profitable business is the speculation with more borrowed money. No matter how many regulations appear, *the tendency* to crisis is incorporated in the system. It cannot be avoided than with the total reformation of the system. The moral hazard is more present because of the governmental regulations, such as the guaranteed program for deposits. The discreet reglementation policy of the state is appreciated in some circles that replce the private management of the risk. In this approach it is ommitted the fact that the bank activity would have become really cautious, having as effect a considerable decrease of the creditation volume and implicitly the slowing down of the real developing economy. The surplus money inducted to the bank system a *growth of the indebttness rate*, so an accentuation of the risk of the impossibility to regain the money, considering that an important part of the credit was given under the practicable standards until the moment of enacting the “money in excess” policy.

The American government launched an encouraging credit programme for the poor population considering an older policy of growing the number of house owners. The legislative measures enacted with such a purpose misled the credit assignment, as it stimulated house construction expansion and the growth of the number of non-performant credits (subprime). The appreciation of this policy is dual: on the one side, it can be considered the category *oldies but goldies* of the populist promises, and, on the other side, it cannot be denied its aid at the development of the economy. When the crisis began, the volume of the guaranteed subprime mortgage credits was of 1 trillion of dollars, contributing decisively at the growth and fall of the speculative real estate balloon.

A similar situation, of *regulation by-pass* by the financial institutions developed in the European Union, too, with the Basel I and Basel II Agreements. The bank institutions started to innovate in order to find the most profitable ways. The first step was to modify the portofolio's structure by increasing the weight of the risky assets. The next step was to eliminate the assets with a high level of risk outside their own balance using to such a purpose complex financial instruments obtaining the indirect lending of the

economical agents through specialized institutions, thus, avoiding the necessity to grow their own capital. The short presentation about the involvement of the American state in the issuance of the non-viable bonds on a long term and the practice of European banks to pass-by the provisions of Basel I and Basel II, raises the question if the bank system and the financial market, generally, must obey some regulations or must they be let free. When regulations are imposed, they constrain the banks to give up their independent policy and to adopt standard models of quantitative evaluation of the risk. If no rule is imposed, the banks are preoccupied to identify profitable investment projects and would accept an adequate risk to the accepted limits.

2. Structural crisis in Romania

The Romanian economic crisis has internal causes found in the mingled macroeconomic policy adopted in the 90s'. The lack of external debt, in the conditions of an articulate economic strategy, it would have permitted the attraction of important capitals for the retechnologisation of some economic departments with positive effects for the export productivity and competitiveness. But the situation was not like this, for long periods of time it was chaotic. Getting back on a normal course of economic development after 2000 happened on exhausted bases on short and medium term. The main growing factor was the private consume, plus services and agriculture. Consume was stimulated by the credit facilities for natural persons. The same facilities were enacted for economical agents, too, but because of the lack of ample investment programmes, nobody could exploit them. Thus, the most important way to support a long term growth was lost. Among the growing factors, we mentioned agriculture, but the production in this sector was positive as a result of the climatic factors and not because the investments.

If the actions from the American economy led to a world crisis, the evolutions from the Romanian economy led to its own crisis which, accidentally, happened in the same period of time. The consequences of the local policy are defined by two negative effects:

- the growing index of labour productivity is inferior to the growing index of the wages;

- the exponential growing of the current account deficit as a following of the exacerbate private consume by creditation.

The causal analysis of the world and Romanian crisis put into light the following aspects:

- the economic crisis from Romania is of internal, structural nature and it would have been impossible to avoid it even in the absence of a world financial crisis;

- Romania's connection with the external financial market can be done, mainly, through the bank system, an important part of it is made up of the branch offices of foreign banks;

- the external economic crisis affected Romania at the level of the current account by diminishing the volume of the exports;

- as the causes and the transmittion mechanism are different, the measures of ending the crises cannot be similar in Romania and in the other developed economies.

Tabel.1. Comparison between crises types

	External economic crisis	Internal economic crisis
Structural causes	Market liquidity excess Misuse of the financial fluxes from the real economy towards investments	Private overconsume by excessive creditation Wages index superior to the productivity index
	Speculative balloons on more markets	Speculative balloons on real estate market
Transmission mechanism	Exposure to risky and nontransparent derivates to obtain short term profit Speculation in the real estate market stimulated by credit policy	Financing the current account deficit Strict reduction of the capital entrance as ISD
Adjustment mechanism	Anti-cyclical policies: - growth of budgetary deficit - growth of public expenses	Pro-cyclical policies: - reduction of budgetary deficit - reduction of public expenses

Generally, there are more causes of the economic crisis from Romania, without a prior unanimity: too fast liberalization of the capital account, consume stimulation based on short term external financing, budgetary and fiscal policy, postponement of structural

reforms; reduced absorption of structural funds; crisis denial before the 2008 elections, which led to the postponement of some prevention measures and to the growth of disbalances.

The liberalization of the capital account finished in April 2005, once with the implementation of the most important stage: the access of non-resident persons to lei deposits. Besides the benefits, such as the assignment of capitals towards most productive usages, the reduction of financing costs; the growth of the financial system depth, etc., may also appear major risks which if they are not fought back in real time can manifest with a great amplitude. The possible induced risks of liberalization are: the excessive growth of the credit volume; the exposure of sudden capital entrance and exit by portfolio investments and rapid appreciation of the national currency with an impact upon the current account deficit.

Prevention and attenuation of the manifestations of such risks can be done through: predominance of direct foreign investments in the financing of the current account deficit; a careful fiscal policy, with as lower budgetary deficit as possible; discouragement of the speculative capital entrances with a reducing interest rate policy and a flexible regime of the exchange rate. Though, massive foreign capital entrance, greatly speculative capital, attracted by the rates six times higher at the lei in comparison with the euro, determined the appreciation of the exchange currency rate. Between October 2004 and July 2007, the currency exchange rate appreciated with 35%. At the question if it was a correct approach or it was necessary a gradual approach for the liberalization of the capital account can be presented pro and con arguments, it is sure that it had to reach this point and, especially, to act decisively in order to avoid negative effects.

The efficiency of the deposits in the national currency was the main growth factor of the current account deficit. The foreigners started to keep their economies in Romanian banks, and the branch offices of the foreign companies preferred to get short term loans from abroad and to speculate this money in Romania, as they gained both from the rate interest difference and the exchange rate. But this it is only a volatile financing, money can

disappear at any time if the market conditions change. And the conditions started to change in August 2007, when the lei started to depreciate. The growth of the reference rate can determine the staying of the capital in the Romanian banks, only that such a move is favourable for the speculative capital. In contradiction, the productive capital is stimulated by funds with as lower costs as possible. "*The fever of the excessive consume from loans, remains the main cause of the crisis*" seems to be a sufficient argument for the situation in Romania. The stimulation of consume was assured by the growth of the external debt on a short term. The total external increased from 18 billiards of euro in 2004 to 72 billiards of euro in 2008. At the end of the IIIrd trimester of 2008, so at the climax of the economic growth, as from the IVth trimester of 2008 it started the economic deceleration, the external debt on short term represented 33 billiards of euro, of which 99% was a private debt. The non-governmental credit increased from 10% of GDP in 2001 to 39% of GDP in 2008, in the conditions in which the GDP increased over 4 times in nominal terms in this period. The nongovernmental credit registered a change of weight factor in favour of the credits given to the population from 30% in 2004 to over 50% in 2008.

Ever since the summer of 2007, the credits given to the population exceeded the deposits in the banks. This phenomenon was objective considering the population's income and the value of the savings could only have a low procentage. The consume leap by credits could not have had these consequences if the real economy had had a different structure. The private consume was stimulated by the evolution of the real estate market, too, the increase of the houses and land prices in an alert rhythm guaranteed the obtainance of a proportional volume of credits. *The fiscal and budgetary policy* is the main way of intervention of the state in economy. A fiscal or budgetary policy is procyclic and then it exacerbates the fluctuations of the economic cycle. The economic science connexes procyclic policies to the corruption level in a country. The budgetary income never got over 32% of the GDP, the lowest level in the EU, although it could have been possible in an economy with high growth rates. Many investment

expenses are not justifiable both as destination and as volume. Other part of the expenses can be found in the wages growth superimposed over the election campaigns. The nominal growth of the budgetary wages in the period 2005-2008 was of 86%. When one has high rates of economic growth, it is not possible to have high budgetary deficits. The main cause of the crisis is represented by the postponement of the structural reforms. In the conditions of the dis-industrialisation from the 90s' existed a weak preoccupation for the attraction of direct foreign investments and the stimulation to invest the local capital. An extremely negative role is the fact there was no adequate infrastructure. The great agricultural potential of Romania had no great investments, the peaks of production were obtained thanks to the favourable climatic conditions. In the present conditions when the price of agricultural products is increasing it is absolutely necessary a national strategy in the field. It is unacceptable the perpetuation of this situation from 2010 when millions of agricultural land hectares were not cultivated. The Romanian economy was and remains the most energy eating economy from the EU, with a medium consume 6 times higher than the EU average.

Romania took the most inefficient anticrisis measures according to the research center in the economy field, CESifo Group. The anticrisis measures from Romania received only 1,3 points from CESifo. Romania's brief is only a bit above the "insufficient" grade, although there were a number of 12 measures. The solution of a healthy economic growth in Romania, it must be the one proposed by the developed countries, that is, to create new jobs, it is considered to be the most semnificative indicator for crisis transgression. The level of occupation of labour force is situated under 60%, a lot below the target established through Lisboa Agenda at 70%.

In Romania the anti-crisis measures pointed, on the one side, to diminish the budgetary expenses by reducing salaries and social expenses, and, on the other side, the growth of the incomes through suplimentary taxation of the work force, the introduction of the minimum tax on the turnover and the rise of the VAT with 5%. Even with limited financial resources, many emergent economies have implemented staffing stimulation measures, among which we mention: Czech Republic reduced the health insurance contributions paid by the employer and the employee; Poland reduced the tax level on income; Hungary tripled the funds allocated in 2009 than in 2008 for public works of local infrastructure; etc. The economy cannot be restored by reducing the occupation and implicit reducing the effective request. There are even other efficient resources in the economy and in the incomes at the budget which were not exploited. The most obvious is the reduction of the tax evasion of which causes are to be found in the taxing and in the corruption. Bringing up the "grey" economy can be done by diminishing the taxation burden just like in the American economy. It is important the position of foreign investors towards the multiple changes of taxing in 2010. They labeled as "impredictable" the Romanian economic environment and that the risks on long term financial projections are too high.

Abstract

The immediate postwar period included Romania in the USSR influence sphere and marked its evolution, leading to a socialist self-isolation from the other countries of the world, which diminished considerably our country's chances to anchor itself to the international division of work and to the world circuit, to keep up with the international economic progress. But the changes in the political landscape, from Central and Eastern Europe, at the end of the eighth decade of the xxst century, led also to major changes in the economic field. One by one, the countries under the communist domination passed into another evolutionary stage, wishing strongly to become democratic states and free market economies. Romania's adherence to the UE generated profound mutations in the developing of goods trade and marked the passage of our country into a new stage of aperture, development and setting of policies and business strategies.

Key words: exterior trade; imports; exports; trade balance

J.E.L. classification: F14, F15

1. Introduction

The communist period let a notable mark on the entire Romanian economic system, and the evolution of the external commercial relations was strongly marked by the orientations of the centralized leadership, which completely contradicted the theses, the concepts and the objective economic laws. According to the declared data, between 1950 – 1989, the total value volume of the Romanian exterior trade recorded an annual

average developing rhythm of about 10%, increasing about 36 times, the export 42 times and the import 29 times [1]. Comparing the Romanian exterior trade average growth rhythm of 15.75%, during 1960-1980, with the other national economic indicators: GDP = 9.5%; industrial production = 12%; income level = 11%; one can notice that the trade activity overcame all of them.

The period between 1981 – 1989 was strongly marked by the Romanian exterior trade correction measures, powerfully centered on reducing the external debt – through anticipated payments, by increasing the exports and decreasing the imports. The psychosis of paying the external debt led to the restriction of population consumption and to the country's isolation in the international environment. In the first decade of 1989, Romania became a country without external debts, with an excess trade balance, but with a population brought to the brink of despair. Our country share in the international trade, of 0.5% at export and 0.3% at import, expresses, unfortunately, our vulnerability towards the external competition environment and the inferior position towards other developing countries, with similar national potential or with an even lower potential than the Romanian one.

2. The evolution of the Romanian exterior trade during 1990 – 2006

Romania's start in the transition process towards a market economy was a complete failure, economically and socially. **The Romanian exterior trade** knew a powerful decline beginning with 1990, situating itself in 1991 below 50% from the level reached in 1989. If the **export** represented, in 1993, about 40% from the level reached in 1989, in

the following years, although a certain recovery was recorded, it was by 1.6% smaller in 1998 than in 1997 [2]. Practically, the level of the **Romanian exterior trade volume** from 1989 was reached in 1995. The **volume of investments** in economy represented, in 1992, about 20% from the one recorded in 1989, the **currency** depreciated about 100 times, the **inflation** reached three figures, the **prices** increased dramatically, at the beginning of 1993 the **unemployment** exceeded 11% of the total active population, and the living standard decreased catastrophically [3]. **If in 1988 Romania occupied the 38th place in the world trade, in 1999 occupied the 60th place.** This sad painting of Romania's first years of transition towards a market economy expresses the image of the economic recession given the lack of coherent governmental policies and stable economic developing strategies, during a long or average period of time.

Source: Processed after: National Institute of Statistics, Yearbook of International Trade of Romania, 2008, p.23

The structure of the Romanian exterior trade on products degraded strongly during Romania's transition period, as the share growth result of the low added value products detrimental the high tech products. But starting with 2004 one can notice the ascending trend of the high added value products and the decrease of the low production. Practically, after a long period of time, the exports of cars and mechanic devices, apparatus and electrical devices, recording devices and devices for the reproduction of sounds and images have exceeded the exports of clothing, manufactured or fabrics, knitted or crochet, textile materials.

The geographical orientation of Romanian exterior trade during 2002 – 2006 was especially towards the EU countries, on average 68.6% at export and 61.1% at import, reaching the maximum level in 2004. Italy and Germany remained the main commercial partners of Romania, with an average at export of 21.5% and respectively at import of 17.5% and 14.7%. If before 1990, half of the Romanian exports were orientated towards the former socialist countries, in 2006 the exports had as preponderant destination the countries with market economy.

Analysing the destination of the **Romanian exports** the following aspects are emphasized:

- If in the first two years of the analysed period, 40% of the total Romanian exports were concentrated in two countries (Italy and Germany), starting with 2004 the exports towards Italy started to decrease, being, in 2006, smaller by 30% than in 2002.
- The exports towards USA had an oscillatory, but negative, evolution which placed it from the fifth place in 2002 on the ninth place in 2006.
- Turkey ascended rapidly in the classification, from the sixth place in 2002 to the third place in 2005, almost doubling its share.
- Greece got out of the top ten in 2005 when Bulgaria entered.
- The ten partner countries totaled, during the analysed period, about 72.7% from the total of Romanian exports, and EU about 68.6%.

The orientation of the **Romanian imports**, on partner countries, during the analysed period, shows the following evolutions:

- Almost 40% from the Romanian imports were concentrated in Italy, Germany and Russian Federation. But starting with 2003, Italy starting losing as share, in the total of imports, and in 2006 was overcome by Germany, which became the first partner at import.
- Although France had a slightly oscillatory evolution, it maintained itself on the fourth place, except for 2004 when exceeded the Russian Federation and reached the third place.

- Turkey increased its share permanently and ascended from the eighth place in 2003 to the fifth place, maintaining this position in 2006 too.
- USA, Netherlands and Great Britain left the top ten. Starting with 2003 China entered the top and ascended rapidly from the ninth place up to the sixth place, doubling its share in 2006 from 2003. Kazakhstan and Poland are the new countries which entered the top, starting with 2005, with a share of 3.2% and respectively 2.8% in 2006.
- The ten partner countries totaled, during the analysed period, about 67.4% from the total of Romanian imports, and EU about 61.1%.

There's no doubt that the Romanian exterior trade development, during the transition period, with a limited number of countries, in an overwhelming majority UE member countries, confirms the orientation of the external economic relations of our country towards this area. Naturally, the access on a demanding market leads to a stimulation of the national potential in order to increase the competitiveness and to improve the export characteristics. But Romania lost, by giving up to the traditional safe sources of indigenous products sale.

3. Evolutionary aspects of the Romanian exterior trade, after the adherence

In the first three years from the adherence to the EU, the Romanian exterior trade structure was dominated by six groups of products, which controlled, on average 75.5% from the total of exports and 74.8% from the total of imports. Five of these can be found in this top, at export as well as at import, and the exception comes from the group *Plastic materials, rubber and this kind of articles*, which can be found only in top six at export and from the group *Chemical products*, for the import.

The group *Cars and apparatus; electrical equipments; devices for recording or reproducing sounds and images (XVI)* increased its share in the total of Romanian exports from 22.2% in 2007 up to 26.4% in

2009 and in the total of imports, from 25% to 27.1% maintaining itself on the first position in the classification, in both flows. The group *Mineral products (V)* oscillated between increases and decreases, and the groups: *Textile materials and this kind of articles (XI)* and *Common metals and this kind of articles (XV)* decreased as share in the total of exports. The group *Means and materials for transport (XVII)*, ascended from the fourth place up to the second place, at export and descended from the second place to the fifth place at import. The group *Chemical products (VI)* increased its share in the total of imports, ascending from the fifth place to the second place in the classification.

The geographical orientation of the Romanian exterior trade in the first three years since the adherence, was inside the EU, with an average of 72.2% at export and of 71.3% at import, growing from the period previous to the adherence. Romania had in 2009 commercial relations with 205 countries [4], by 4 more countries than in 2008 and by 12 more countries than in 2007. Italy and Germany remained the main commercial partners of Romania, with an export average of 15.9% and respectively 17.3% and with an import average of 12% and 16.9%. [5]

Analysing the **Romanian exports** destination, in the first three years since the adherence, the following aspects stand out:

- The concentration remained in two countries (Germany and Italy) in an average percent of 33.2% from the total of exports.
- Italy was overcome, starting with 2008, by Germany, who became the main commercial partner of Romania at export too.
- USA got out of the top 10, starting with 2007.
- Turkey and Hungary descended progressively, as share, in the total of exports.
- Poland got out of top 10, in 2008, and Netherlands got in.
- The ten partner countries totaled, during the analysed period, on average 66.7% from the total of Romanian exports, with a descending tendency, and the EU on average 72.2%, ascending from the period prior to the adherence.

The orientation of **Romanian imports**, on partner countries, during the analysed period show the following evolutions:

- Almost 29% from the Romanian imports were concentrated in Germany and Italy, the first two partners at import. After a decrease of the two countries in 2008, from 2007, Germany reconfirmed its ascending trend - Germany ascended slightly as share, but Italy remained below the level from 2007.
- The Russian Federation and Turkey decreased, as share, from 6.3% and 5.3% in 2007, to 3.9% and respectively 3.7% in 2009.
- Hungary maintained itself on the third position, increasing as share in the total of exports of our country.
- China entered in top 10 in 2003, with 2.7% of the total Romanian imports, and followed a constant ascending direction, holding in 2009 almost 5%.

The ten partner countries totaled, during the analysed period, on average 68.5% from the total of Romanian imports, in a slightly growth from the period previous to the adherence, and the EU on average 71.3%, increasing with 10.2%.

Source: <http://www.arisinvest.ro/ro/de-ce-romania/date-macroeconomice/>; *INS, BNR*.

Under the impact of world economic crisis, the economic activity from our country reduced notably, generating a sudden decrease of the exterior trade during 2009, with 25% less than the previous year. The economic context in Romania became less favorable than the previous years, and the crisis reverberations were felt economically but also socially. In 2009, the economy decreased with 7.1%, the final consumption decreased with 8.2%, the prices increased, on average, by 4.3%, the budget deficit wes of 7.3% from the GDP, the current account deficit of 5.5%, and FDI totaled 4,4 billion Euro [6].

4. Conclusions

In the first eight months of 2010, according to the estimations made by the Romanian Center for the Promotion of Trade and Foreign Investments, the exterior trade totaled 52.746, 6 million Euro, growing with 22.1% from the same period of the previous year, the export recording a growth up to 23.315,6 million Euro (+25.3%), and the import up to 29.431,0 million Euro (+19.7%). Romania continued to develop the trade inside EU, with 20.5%, from the first eight months of 2009, the exports being by 4.6% larger than the imports, and the trade balance deficit in the relations with the EU partners increased by 3.6%. The extra – communitary trade increased by 26.6% , with a larger rate at export (+31.5%) than the import (+23.0%), and the trade balance deficit outside EU decreased by 0.9%.

Due to the trade pronounced increase on the extra – communitary relation comparative to the intra – communitary one, the share of the commercial exchanges with the EU countries decreased from 73.4% in the first

eight months of 2009 to 72.5% in the first eight months of 2010[7].

The Romanian exterior trade continued to be significantly orientated towards Europe, in a proportion of 89.1% from the total of exports and 87.4% from the total of imports. In the relation with the member states of the EU, this was of 72.5% at export and 72.4% at import, Germany and Italy remaining the main commercial members, which hold 32.2% from the total of exports and 28.7% from the total of imports.

The Romanian exterior trade remains vulnerable due to the lack of a coherent developing strategy, orientated towards the growth of our competitive national advantage. Making more efficient the economic sectors, focusing on the industry, agriculture, services and infrastructure, on the exploitation of the European funds through eligible projects, the development and diversification of the export offer, the growth of the high added value products share, in the total of exports, the reduction of trade deficit, are objectives of national interest, of maximum urgency, for the economic development and, implicitly, for the commercial development of Romania.

Abstract

For the catering services, the economic efficiency includes the consumers' satisfaction and the guarantee of the hygiene of products.

The integration into the EU imposes obligations on all service providers that are related to human nutrition.

In this context, McDonald's promotes four basic principles of business philosophy: Quality, Service, Cleanliness and Value. These principles are valid in every restaurant in the world.

The focus on the customer, the employee value, material management and the permanent improvement are the most important quality objectives that McDonald's is trying to achieve.

Although it seems to be a large corporation, McDonald's is actually a system comprised of a lot of small units and of individual franchisees, the McDonald's entrepreneurs.

McDonald's is a leader in this business, as it is both a global and local service company, as well as a franchising company.

The company's business strategy is focused on opening new restaurants, maximizing profits and sales volume.

Key words: strategy, business, McDonald's, management.

J.E.L. classification: L21

The market economy mechanisms impose the criterion of economic efficiency in the organization and the development of the economic activity.

For the catering services, the economic efficiency includes satisfying the consumers' guarantee metabolic requirements and the guarantee of products in terms of individual health.

Romania's European integration imposes obligations on all service providers related to human nutrition.

In this context, McDonald's promotes four basic principles of business philosophy: Quality, Service, Cleanliness and Value, available in every restaurant in the world.

Quality, the most important principle of the company, is particularly highlighted in the selection and preparation of products. The restaurants offer 100% fresh products at any time of day, and their schedule was extended even on holidays.

The techniques used by McDonald's ensure product quality and are recognized by certified national institutions and are often more stringent than the limits set by authorities.

The quality control process is not even over when the product is packed and is waiting to be consumed by the customer. The control system covers the entire production process from raw materials to finished products.

McDonald's menu is continuously diversified with a wide range of sandwiches that often comply with the culinary traditions of the country where the restaurant is open.

The menu is not the typical American one, in some countries it contains products belonging to the national cuisines. But Big Mac is still the favorite product, as a symbol of the company.

High quality products are served in a pleasant, clean environment, at the lowest possible price, without compromising quality.

At McDonald's, quality management is based on four principles: [1]

- ◆ focusing on the client;
- ◆ the employee value;
- ◆ material management;
- ◆ continuous improvement.

Under these principles, to meet and even to exceed the customers' expectations, you need good communication between the restaurant employees and the respective clients. Communication must be open, complete, without distortion, any complaints should be dealt with promptly and effectively. It was found that, in general, one customer out of twenty complained of dissatisfaction.

Serving standards are intended not only for speed but also how to serve, for which the following steps are foreseen:

- use a form of greeting when taking the order;
- assembly the order in the following order: shake, soft drinks, hot drinks, sandwiches, pies, fries, ice cream;
- presentation of order and cashing the money;
- addressing an appreciation formula and an invitation to come back to the restaurant.

Among the team members on each shift there must be a team spirit based on the 3Cs: communication, coordination and cooperation.

On each shift they check the quality of products, the hygiene and the times at which the product expires. They can be kept on the preparation table up to 2 hours (for example, the cheese slices have a time limited to 30 minutes). Also, to prevent any non-compliance or to detect those emerging, quality control is also exercised over the area for the public. So, on the one hand, they check the serving line, and on the other hand, the dining room.

The following aspects are pursued with the serving line [1]:

- the sufficient opening of cash desks in report with the periods of day and the flow of customers, evenly/symmetrically spread over the counter;

- the proper training of the team members regarding the serving criteria;

- directing customers to the free cash desks;

- maintaining an appropriate level for the money change and checking the banknotes of high value.

The reduction of the speed service will cover the following aspects:

- a) queuing up to maximum 2 minutes;
- b) staying in front of the cash desk within 1 minute;
- c) standing in a "drive" window for 30 seconds.

Suggestive selling is an option for undecided customers, focusing on ordering a large portion, unless this was not specified.

The company's business strategy focuses on the following elements:

- a) opening new restaurants;
- b) maximizing the profits and the sales volume through better restaurant management, an intense policy of reinvestment, development and product improvement, cost-effective marketing and reduced costs for development and operation.

Each opening of a McDonald's restaurant means important contracts with local construction and equipment installation companies.

A new McDonald's restaurant in Central Europe creates, on average, about 100 new jobs [2]. The first McDonald's restaurant in Romania was opened in June 1995 in Bucharest, within Unirea Shopping Center.

McDonald's is a world leader in business because of the following characteristics:

→ it is a service company, which aims to satisfy customers' desires by quality food, in a fast and friendly service, and an environment known for its cleanliness and providing a menu that is worth its value;

→ it is a global and local company, involved in marketing;

→ is a property development company - about 60% of the places where McDonald's restaurants are built represent company properties, others are leased through long-term lease agreements;

→ it is a franchising company.

Worldwide, about 66% of McDonald's restaurants are operated by independent franchisees, 21% are operated by local branches of McDonald's Corporation and

13% are operated under license by association [2].

McDonald's is known for its restaurants principle of providing services and products needed by local independent producers, accepting only those that can provide standard quality products to McDonald's since the beginning of their cooperation.

Although it seems a large corporation, McDonald's is actually a system composed of many small units and individual franchisees, the McDonald's entrepreneurs.

Franchising [3] is a modern system of selling goods and services, based on a long-term cooperation contract (approximately 20 years) between two independent legal partners:

- the franchisor – McDonald's;
- the franchisee – the business entrepreneur partner that can have between 60 and 100 people in his restaurant.

The one who receives the right franchise can use the trademark, company facilities and rights of the authorized franchise.

Given these issues, McDonald's believes that the following qualities are essential for the application to obtain a franchise agreement:

1. entrepreneurial spirit and a strong desire for success (obtaining an extraordinary profit, which often requires significant investments);
2. extensive business experience, with emphasis on developing sales;
3. willingness to participate in specific training lasting 10 to 14 months;
4. geographical flexibility, considering the possibility of moving to other cities;
5. financial flexibility to have a good start in the business.

The strategic location of the restaurants, their construction and equipment-making are made by McDonald's on the basis of its broad experience, according to a long-term business strategy. Thus, the partner of the firm receives ongoing support throughout the franchise. He also benefits from the stability of a national advertising strategy.

As for the financial demands of the franchiser, they can charge a fee. Part of the restaurant franchise costs must be supported from personal resources and the rest can be financed from other sources, according to the method of acquisition [1]:

- the BFL method - Business Facilities Lease – the leasing package of current activities requires a certain amount payable in lei. It represents a guarantee (no interest deposit), the stock of food and package products and the costs of preparing and opening the restaurant (the training staff and the managers, an initial set of uniforms, the campaign ad);

- the direct conventional method, which requires a certain amount payable in lei. It represents the minimum of 60% of McDonald's assets that may increase, depending on the size and position of the restaurant current assets. The acquired assets consist of an interest rate (no interest deposit), an initial franchise fee and the cost of the restaurant equipment.

McDonald's does not provide financing for the letters of credit for loans and does not allow any investors as third parties.

In the current context, traditional indigenous affairs, with well-established franchise networks working on the food and services segment, are the most sought to place franchise investments. The investments on the food segment are made in fast-food concepts (take away food) and less on the segment of franchise restaurants, where the sitting time is influenced by the consumer's purchasing power [4].

The Prospects of the European Social Model – A Post-Crisis Approach

Voicu Victor

Academy of Economic Studies, Bucharest
Doctoral School, International Business and Economics
pinnconsult@gmail.com

Abstract

Since the mid '80s Europe has tried to assert a single common social model with better welfare and social inclusion than its ultra-liberal competitor – the United States. The reality shows that many different social models coexist in Europe and they have been put to a tremendous test during the recent economic crisis. Some of them have bitterly failed this test and must undergo deep structural reforms.

On the other hand, the recently exposed shortcomings of the neoliberal paradigm require a profound reconsideration of the role of the state as a regulator of imperfect markets.

With its flaws revealed in the aftermath of the crisis, Europe has a unique opportunity to move forward in promoting a smart, sustainable and inclusive growth.

Key words: European Social Model; welfare state; labor market; social inclusion

J.E.L. classification: F15

1. Introduction

The financial and economic crisis of the last three years still generates consequences that few economists and scholars have guessed at its outset. The original crisis within the banking system, which the governments seemed to be able to contain through unprecedented bail-out packages and/or nationalization of crippled financial institutions has soon overgrown its hatching environment and burst into the faces of the same governments in the form of huge deficits that triggered the sovereign debt crisis.

This chain of events that swept throughout the developed world has led the public opinion to raise their voices and point fingers

at fundamental concepts and paradigms that the Western world had taken for granted such as globalization (that led to a worldwide contagion), the neoliberal paradigm (that failed in its claims that de-regulation is best because the private sector is superior to the government in the optimum allocation of resources) and even capitalism itself (whose mantra that profit is king proved detrimental to millions of citizens confronted with layoffs, foreclosures and insecurity).

The harsh reality is that the markets are far from being capable of fixing themselves and the governments have a social responsibility to step in and try to fix what has been damaged because of their neutral and rather contemplative position to the abuses of the almighty market forces.

The European Social Model, with its claims of superior welfare states and large public sectors (compared to the US) failed to prove its strengths in the face of these developments. This, along with the underlying economic challenges of today (increased competition from US and China, the prospects of an ageing population etc.), prompted the European Union to reconsider its strategies and priorities (severely hurt and undermined after the failure of the ambitious goals set under the Lisbon strategy).

2. The European Social Model(s)

The term "European Social Model" is widely attributed to former President of the European Commission Jacques Delors who introduced it in the mid '80s by designating it as an alternative to the American (and British) pure form of free-market capitalism [1]. In retrospect, this politically charged term was launched to give weight to a European identity that was yet to be outlined and to propose an alternative to the ultraliberal capitalisms of the United States and the United Kingdom [2].

Officially [3], the term was intended to designate a set of common values, namely the commitment to democracy, personal freedom, social dialogue, equal opportunities for all, adequate social security and solidarity towards the weaker individuals in society [4]. The strength of the model would thus reside in the mitigation of two critical concepts: competitiveness (sustainable economic growth) and solidarity (social cohesion).

To this day, the term has been associated more to a political abstraction rather than to an actual and coherent body of shared social principles to which all Member States adhered. Different national values, traditions and priorities naturally resulted in different policies and mechanisms governing more strictly or loosely the labor markets and the social security systems. The result is a diverse collection of rules and policies that vary greatly from one European country to the next. So instead of speaking of a unique European Social Model, some authors [5] argued that there were at least four distinct social models within the EU, namely:

- (i) the Nordic social-democratic welfare states (Scandinavian countries plus the Netherlands) with the highest levels of social protection expenditures and provision of universal welfare, which results in a high degree of inclusion and social cohesion;
- (ii) the Continental corporate welfare states (Austria, Germany, Belgium, France) with insurance-based benefits, heavily unionized workforce, collective bargaining and last resort services provided by the state;
- (iii) the liberal or Anglo-Saxon welfare states (United Kingdom, Ireland) with high involvement of the private sector in social security and very flexible labor markets, which triggers wide dispersion of wages and higher levels of social exclusion;
- (iv) the Mediterranean welfare states (Greece, Spain, Portugal, Italy) with very high job security and high benefits based on seniority, which triggers high levels of youth unemployment and gender divide, as well as a highly compressed wage structure.

There are clearly many differences between these social models. So, how can Europe claim to oppose the US with a single

common social model?

We need thus to look at the common denominators of Europe's four main social models. To start with, most European governments have a rather long-standing tradition of interfering with labor market mechanisms, especially when it comes to minimum wages or maximum working hours, but also collective bargaining, power conferred to unions etc.

More importantly maybe, Europe has long struggled with (or enjoyed, depending on which side of the debate you are) large public sectors. This does not automatically translate into the appetite for bureaucracy on which many Euro-skeptics like to focus. A large public sector has often meant wider, better and cheaper (if not free) access to social services such as health, education, culture etc. which usually translated into fewer discrepancies and higher social inclusion. However, the dimension of the state has not been limited to the provision of these basic services. The state has often been an active player in the markets in areas as varied as energy (production, transport and distribution), resources, manufacturing, banking etc. One of the advantages of retaining some state-owned banks has become clear during the recent crisis, where some governments were able to intervene directly in the economy instead of relying only on indirect measures. Conversely, some governments faced difficulties in persuading private banks to lend some of the money they received as part of the banking sector bailout packages [2].

Last but certainly not least, virtually all European governments have developed comprehensive welfare states that cater for the vast majority of the population. In contrast to the USA, where the welfare is privatized and therefore not granted to all citizens, the European countries have shared the principle that welfare should cover all citizens and must remain one of the main prerogatives of the government.

These common traits of the various social practices that co-exist throughout the continent entitle Europe to claim a unique social model as its own. Moreover, the value of this model is fully supported by statistics and economic indicators showing that Europe has a significantly smaller proportion of poor

citizens and consequently a higher degree of social cohesion than the US, for example.

Nevertheless, the performance of Europe's four main social models has varied greatly. Some of these models seem to be more sustainable and have escaped the recent crisis virtually unscathed, while others (most notably the Mediterranean welfare states) have barely survived the recent turbulences and are currently undergoing painful adjustments of their inner mechanisms.

3. EU sustainable growth strategies: Lisbon and Europe 2020

Faced with the challenges of globalization and increased economic competition with other economic blocks (USA, China and Japan), but also with the imminent consequences of a ageing population, the European Union launched the Lisbon Strategy in 2000 as an ambitious project to coordinate the economic and social policies of the 15 member states.

The declared objective of the Strategy was to transform the Union in the most dynamic and competitive knowledge-based economy in the world by 2010 capable of sustainable economic growth with more and better jobs and greater social cohesion.

The review performed halfway through the implementation period (through the so-called Win Kok Report in 2004 [6]) revealed that, despite some progresses (increased occupancy rate among women, development of the knowledge economy etc.), the most important objectives of the Lisbon Strategy were not achieved for reasons such as (i) lack of political will and action; (ii) too many and too vague objectives; (iii) poor coordination of actions at national and EU level; and (iv) differences in the priorities of the member states.

In fact, the very objectives of the Lisbon Strategy – economic competitiveness and social cohesion – could be viewed as antagonistic. It is hard to imagine a manner in which the EU could become more competitive than the most liberal economy in the world (USA) and at the same time ensuring an increased social cohesion.

In the context of the partial failure of the Lisbon strategy and faced with the new challenges induced by the world economic

crisis, rising unemployment, sovereign debt and public deficit crisis, in March 2010 the European Commission proposed a new 10-year strategy (Europe 2020), aimed at providing the necessary thrust to the European economy. Its declared purpose is a "smart, sustainable and inclusive growth".

The strategy proposes three mutually reinforcing priorities, namely

- (i) smart growth: development of a knowledge- and innovation-based economy;
- (ii) sustainable growth: a more efficient, competitive and environmental- friendly economy;
- (iii) inclusive growth: an economy with a high occupancy rate, investments in skills and training to ensure social cohesion.

How can these objectives be met in the aftermath of a deep economic crisis, if similar goals failed to be reached during far better economic conditions? No one can guarantee a more coherent coordination of national policies or the adoption of a single list of priorities, now that the national governments are consumed with fighting their way out of the crisis and maintaining the recent fragile signs of growth.

4. The aftermath of the crisis

As in all hard times, the answers should rest precisely in the very nature of hardships that the member states have to endure.

The economic crisis acted as a very accurate diagnostic tool that exposed bluntly all the shortcomings of each individual social model, as well as their overall lack of harmonization. So the governments need to focus on the weakest links in their respective social policies.

Perhaps the most important action that is required in the member states that nearly collapsed during the crisis is a deep reform of their labor market conditions. Some deeply rooted habits and traditions should be shaken because they created patterns of behavior that are no longer sustainable in a rapidly ageing society. All barriers to enter the labor market should be removed, especially for the young people; public employees should not be immune to layoffs; remuneration should be linked to performance rather than seniority; retirement age and social benefits should be

revised; some public services should be made more efficient through privatization, while others might need more regulation etc.

Some governments need to be involved less, while others need to be more present in regulating the markets. In any case, the governments can no longer ignore the obvious signs and leave the almighty market to fix itself because the harsh reality of the last three years clearly demonstrated that more but smarter regulation is needed.

The governments might take some solace in the fact that it's their turn to show their regulatory muscles, after years of being played down and told that globalization did not need them anymore. This happened because an all-encompassing market did not need its dominion fragmented by old-fashioned concepts like sovereignty and could not trip itself on myriad of local, regional, national or supranational regulations. Moreover, any abnormality in the functioning of the market was for the market itself to fix, not for bureaucrats that could not understand the merits of free market.

Authors [7] have argued that the globalization as the neoliberal theory asserted it must live its last moments and should be replaced by a "smart globalization" where smart governments should assert a more important role as regulators and guardians of the best interest of their citizens.

With this end in mind, thanks to its institutional architecture Europe appears uniquely well-placed to do just that because whatever a single government might not be able to impose to large corporations might be easier enforceable through the political and economic clout of the Union.

5. Conclusion

Although the European Social Model might still be more a political assertion of a common identity than a functional reality, the recent economic crisis may provide the perfect trigger for a substantial reformation of Europe's flawed social models. Governments of member states can no longer ignore the critical faults revealed in the aftermath of the crisis. They must act both individually and collectively to improve their social systems and to give the necessary thrust to the European economy in its ambitious pursuit of a smart, sustainable and inclusive growth.

Optimum Currency Areas Theory: Economic Foundation for Monetary Unification

Voinea Gheorghe

"Alexandru Ioan Cuza" University of Iasi

Avădanei Andreea

„Alexandru Ioan Cuza” University of Iasi, Doctoral School of Economics

andreea_avadanei@yahoo.com

Abstract

The aim of the present paper is to highlight the optimum currency areas (OCAs) theory contribution to the development of European monetary unification. In order to point out its implications, we structured our research on two parts. The first one illustrates the main achievements and limits of monetary cooperation at European level and the second analyses OCA theory's influence on Economic and Monetary Union (EMU). We conclude by saying that this theory could not provide a clear answer about the optimality degree of EU as currency area. We also consider the European model as a laboratory test of OCA proprieties defined by Mundell, McKinnon and Kenen.

Key words: Economic and Monetary Union, optimum currency area, single market, common currency.

J.E.L. classification: E40, E42, F33, G15.

1. Introduction

Nowadays, the European Union (EU) represents the perfect model of integration, but without any doubt, the functioning of its mechanisms remains subject of ongoing debate.

Following the history of the events and factors influencing its development, the general perception about the EU changes very quickly, highlighting a multitude of problems with regard to foreign trade and single market, competitive agricultural policy, financial market and monetary union, alongside issues of social and regional cohesion.

In early 1960s, Robert Mundell constructed the foundation for OCA theory, which analyses the economic costs and benefits of a monetary union, based on the characteristic features of states pursuing this goal. According to his vision, *optimum currency area defines a set of regions where the migration trend is high enough to ensure full employment in the case of a severe shock affecting one of these groups* [1].

McKinnon (1963) added *economic openness* to OCA properties [2] and Kenen (1969) showed that the *diversity of outputs and consumption* can also be a feature of optimal currency areas [3].

Frankel (1999) argued that OCA is a space that demands for *a common currency and a single monetary policy*.

More recently, Mongelli (2002) considers OCA *as an optimal geographic region with a common currency or a group of countries which have irrevocably fixed the exchange rates and are about to unify* [4].

Pelkmans (2003) definition states that *OCA is that area for which the cost of abandoning the flexible exchange rate or the realignment option is lower than the benefits of a single currency* [5].

We believe that the judgments of the pioneering OCA theory stage pointed out very clearly the challenges faced by the countries wishing to form a monetary union, although the theory has evolved over time.

Thus, optimum currency area defines a space characterized by certain features that allow the absorbance of asymmetric shocks without the exchange rate or monetary policy instruments use.

The purpose of this theory is to indicate the most adequate moment and the ideal situation in order for two or more states to create a monetary union.

Generally, monetary integration requires three conditions: *explicit harmonization of monetary policies, a common pool of foreign reserves and a single central bank*. The concern for monetary union is an issue that has generated countless debates. Monetary integration has a long history, Maastricht Treaty marking the transition point from statements of principle to specific initiatives.

2. Achievements and limits of European monetary cooperation

The evolution of monetary cooperation process began with the establishment of the European Payments Union (EPU) on 1 July 1950, a structure that functioned as a clearing house for the European payments.

In 1957-1958, EPU has shown its limits, so that at the end of 1958 the participating countries have decided to switch to full convertibility of national currencies. In formal terms, EPU was replaced by the European Monetary Agreement (EMA), negotiated in order to maintain a zone of monetary stability.

Analyzing the role of EPU, we believe that its abolition was an involuntary step for the European monetary integration. However, one of the most important events related to the process of European integration is the signing and ratification of Rome Treaties. The European Economic Community (EEC) Treaty established a *custom union* and then the *single market*, integration stages logically followed by *monetary unification*.

In December 1969, the Hague high-level meeting established a phased plan in order to create an *economic and monetary union*. Subsequently, the Werner Plan (1970) proposed a challenging objective, that of substitution of national currencies with a common currency or "failing that, national currencies should be interchangeable at a fixed parity" ([6]), and three stages towards EMU, included 18 years later in the Delors Plan (1988).

In order to limit the exchange rate fluctuations of European currencies, at the French president Valerie Giscard D'Estaing initiative, the European Council decided in 1979 the creation of European Monetary System (EMS), as important preparatory step for establishing a monetary stability zone.

EMS was designed in a skeptical context, generated by the oil shock and the failure of monetary snake whose mechanisms have crushed under the international crisis.

Considering its results, we believe that after a difficult start, EMS has greatly contributed to monetary stability within the EEC, but did not lead to a satisfactory coordination of national monetary and exchange rate policies in all states.

EMS has shown its limits and risks, demonstrating that an incomplete form of integration that provided a certain degree of monetary stability can cause a major crisis.

Certain tensions manifested right after 1987 became apparent when Portugal announced in April 1992 its intention to join the system. The decision of Norway, Finland and Sweden to link their currencies to ECU (European Currency Unit) increased EMS vulnerability even further, as a consequence of their competitiveness problems perceived by financial operators.

In the early 1990s, economic recession has led to an increase in unemployment at the European level, the uncertainties on the Treaty of Maastricht affecting EMS even more.

Although EMS fundamentals have remained solid, the lacks of consensus in respect to some features of the 1992-1993 events raised serious concerns about the possibilities of establishing the economic and monetary union.

Given EMS limits and fragility, the Ministerial Council asked Jacques Delors to chair a committee in order to propose a timetable towards economic and monetary union.

Thus, the part of Maastricht Treaty signed on 7 February 1992 concerning EMU caught up the major guidelines of Delors report: *the common currency, the three-phased convergence and the irreversibility of the process*.

The main three stages of EMU creation were designed as follows:

Monetary policy coordination period (July 1, 1990 to December 31, 1993)

This stage began in mid-1990 by the liberalization of capital flows between EEC members and ended in October 1993 with the completion of the Single Market (basically,

according to the Single Act this stage ended on 1 January 1993, before the Treaty entry into force).

Convergence strengthening and technical preparations period (January 1, 1994 to December 31, 1998)

The second phase began in November 1993 with the entry into force of the Treaty and ended in December 1998. This involved setting up the European Monetary Institute, with a main role in coordinating efforts in respect to convergence criteria, as well as making preparations for the European Central Bank (ECB) creation. Within this timeframe, the ECB prepared to manage the practical issues of EMU final stage, i.e. the launch of single currency.

Euro introduction period (January 1, 1990 to July 1, 2002)

This stage was marked by the irrevocable parity fixing between euro and the currencies of participating countries and the actual single currency introduction. Initially, the timeframe involved two periods: if the majority of Member States met the convergence criteria in 1996, switching to this phase would be implemented from 1997, otherwise, the third stage would start on 1 January 1999.

Thus, according to the Maastricht Treaty, EMU is one of the pillars of European integration, conceived as engine for further financial integration in Western Europe, in order to ensure strong economic growth.

EMU was a response to macroeconomic instability manifested in Europe.

Single currency *supporters* argued that the elimination of exchange rate risk reduces transaction costs and facilitates cross border trade and investment flows, enhancing the Single Market and economic welfare based on economies of scale and growing competition.

Alongside the elimination of currency depreciation as a last resort for economic misalignments, the latter determined structural reforms improving national productivity and growth. Considering all these aspects, the launch of the euro has transformed EU into an increasingly strong presence of global economy.

Still, there were many skeptical opinions about the future of the euro, questioning its ability to eliminate country-specific shocks and the interaction between centralized monetary policy and decentralized fiscal policy. Given the diversity of the participating economies, skeptics argued that the power loss on monetary policy and exchange rate would make domestic adjustments to be less than optimal. As regards fiscal policy, which will remain the responsibility of each Member State, the widespread fraud has been the main concern.

In relation to stabilization efforts of other participants, the *free-rider behavior* of some countries can create tensions between fiscal and monetary policy perspective. As last argument, skeptics believed that at the country level, real interest rates would display a pro-cyclical trend, decreasing as inflation increases in the recovery periods and vice versa, transforming the natural shock adjustment into a very difficult process.

Alternative adjustment mechanisms, such as price and wage flexibility or labor migration in the EZ were considered weak or, as federal fiscal transfers, inconvenient. However, the numerous achievements of EMU and the euro have largely abolished the skeptical forecasts of earlier critics.

3. Influence of optimum currency areas theory on EMU design

The major features of the Delors Report, on which the Maastricht Treaty is based, acted mainly to reduce exchange rate volatility risk and the existent misalignments generating significant costs. Given these aspects, common currency is likely to complete the Single Market.

However, many opinions consider that this argument does not provide a direct link, or involves a very weak one at best, to OCA theory ([6], [7]; for example, OCA properties do not appear explicitly in the Delors Report).

Moreover, the "One Market, One Money" Report has displayed a very critique vision on the early-stage OCA theory [8]. There are many factors explaining the above mentioned approach and the expressed skepticism.

Undoubtedly, rigorous concurrent enforcement of all OCA properties would have offered a wide range of results. From a political point of view, this would have not been an attractive proposal in terms of efforts to achieve monetary union. Consequently, the theory of optimum currency areas has been sidelined.

However, we notice the existence of a paradox, in light of the fact that 'One Market, One Money' Report has greatly contributed to reviving interest in OCA theory, bringing together the many strands of empirical and theoretical research (directly or indirectly related to this theory).

Another merit of the Report is that it has supported various debates focused on individual characteristics and potential EMU implications. Reference [9] pointed out that it didn't particularly highlight the impact of monetary unification on economic integration (nor postulated any effect of the kind discussed by [10]).

Empirical studies reveal major implications of increased exchange rate volatility neither on trade nor on international investment flows. This justifies the view of monetary unification as a limited case to reduce exchange rate volatility, resulting in the removal and dilution of uncertainties related to the costs of trading and hedging.

Reference [11] argued that the many shortcomings of OCA theory reduced the expected net benefits of monetary unification; it is possible that real EMU implications to be more favorable than those estimated if applied OCA properties solely.

Although labor mobility in Europe is relatively low, capital mobility is higher and higher, providing an alternative adjustment channel. Meanwhile, the new OCA theory developed slowly. The hypothesis of OCA endogeneity has done the rest, in terms of revitalizing the debate, playing a major role in the political discussions of the '90s.

Considering the juxtaposition between the supporters of a long convergence process in order to foster the harmonization of monetary policies (*the economists*) and those who considered nominal convergence before EMU as a dispensable feature (*the monetarists*), first group issued the five criteria included in the Maastricht Treaty while the second set the final date for commencement of EMU third stage.

We believe there are two particular aspects that must be mentioned. While the OCA theory has mainly considered the positive aspects of monetary unification, implementation and management of monetary union is primarily subject to the normative elements.

First, over the last 30-35 years there have been extensive discussions related to exchange rate arrangements and institutional features of monetary union; what later became the Central Bank or the Eurosystem is just one of those arrangements ([3], [12], [13], [14]).

Reference [15] examines the pros and cons of the two extreme exchange rate arrangements, a *pseudo monetary* union and a *full monetary union*. The first type of arrangement is a precursor of EMS while the second presented similar EMU characteristics.

In his view, a full monetary union can reach at most the stage of introducing a common currency issued by a common central bank, which manages union foreign exchange reserves. It may be attributed the role of ensuring price stability and securing parity in relation to foreign currencies.

Domestic monetary objectives can be set independently, but they may not always be optimal for each individual country or region. At that time, the level of budgetary independence consistent with a monetary union was a very unclear aspect. Thus, Corden (1972) vision attempts to link the two perspectives, *positive* and *normative*.

Second, the creation of a supranational central banking system demands specific arrangements for its future operation. From an organizational and administrative side, the Eurosystem concluded the process of institutionalization of monetary cooperation among central banks began in 1958 with the establishment of the Monetary Committee and 1964, the year that marks the creation of the Governing Committee of the EEC member central banks.

The arrangement proved to be very effective, so that the Governing Committee and its subcommittees prepared in 1990 an ECB draft statute for the future Maastricht Treaty. After its ratification and the creation of European Monetary Institute in 1994, connections between national central banks

(NCBs) have become increasingly systematic [16].

The European path to EMU passes, as proposed by optimum currency areas theory through Single Market. Basically, it suggests certain properties that a monetary union must meet in order to work with benefits: *trade integration* (closely related to the free movement of goods), *free movement of capital and financial integration* and *free movement of labor*, as essence of Mundell's theory.

We believe that the flexibility provided by Single Market creation can replace the loss of monetary instruments as a mean of economic adjustment in the event of asymmetric shocks.

The European Union experience provides an answer to the question: what must go first, completing the single market or monetary union? Today we know that monetary union can not be beneficial in the absence of the integration measures specific to Single Market.

At the same time, a single market can not function properly only in terms of exchange rate stability.

The best way to achieve this objective is ultimately, the monetary union. Further, it raises the level of market integration leading to the finalization of the Single Market, which makes EMU a construction with significant net advantages. Single Market is in fact the beginning of Economic and Monetary Union.

4. Conclusion

OCA theory could not provide a clear answer on the optimality degree of EU as a currency area, the studies results being rather pessimistic. One possible explanation is the fact that classical theory has not assessed the changes effect that occurs after the monetary union in the sense that the discontinuity caused by major regime change may act in the group interest, turning it into an optimal space *after* unification.

Between OCA theory and the European model there is a "from theory to practice" type of relationship ". Thus, we consider the European model as a laboratory "test" of the OCA properties defined by Mundell, McKinnon and Kenen.

The European experience shows that efforts to remove economic and territorial barriers do not automatically eliminate all Single Market distortions caused by differences in the quality of infrastructure, the level of development or the existence of industrial clusters which continue to manifest.

However, the dynamics of economic development, the success of world's largest single market, the creation of the euro area, the existence of common well-defined policies define the unique character of European economic integration process.

Paradoxes in the Diet of Modern Consumer at the Confluence between Food Science and Food Industry

Abstract

Food is a customary part of our daily lives, because living means feeding, but it shouldn't be approached merely as a trivial factor for meeting physiological needs of macro and micro-nutrients, but from a holistic perspective in terms of the social and identity functions and the effects on individual health.

In the last decades, through the application of industrial processes such as refining or hydrogenation and the widespread use of feed additives and genetically modified organisms, considered major innovations in food industry, it was created a distance between man and aliments, which systematically transforms into an abyss, culminated with real alimentary crisis, a result of some breakings in natural order.

This paper highlights the hazards of food industrialization in the nutritionism era and analises the paradoxes which were appeared in the diet of the modern consumer at the confluence between food science and food industry.

Key words: foodstuff, consumer, food industry, food science, paradoxes

J.E.L. classification: O 14, O32, I 31

1. Introduction

Food history is a surprising history of civilizations that has changed and includes several periods, which have lasted thousands or hundreds of years [6]:

- *The first period* began with primitive men who were hunters and harvesters, who ate what they found and migrated to safer places and with more abundant feed.
- *The second period*, between the years 10000-7000 BC, can be considered the first revolution in food, because, after Ice Age, people buried roots and seeds, starting to practice agriculture. In this way it was provided food for entire communities.
- *The third period* began with The Great Geographical Discoveries of the fifteenth-seventeenth century and was manifested mainly in Europe. Europeans began to cultivate potatoes and corn, changing its eating habits. Isolated populations in Asia, Africa, South America and Oceania remained with old culinary traditions, some of them still held today. The keeping of these old culinary traditions is explained primarily by the fact that, in order to survive, populations from some isolated areas were forced to experience all sources of food. Some nutritional resources have penetrated so deeply into local traditions that have become their symbols. In such way can be explained why in these isolated geographical areas were kept until today, some special and strange dishes, inherited from old times.
- *The last period, considered the second revolution in food, started after the Second World War and began in the USA.* Through technology (machinery, fertilizers, storage and transport), agriculture and zootechnics led to a powerful food industry.

The third millennium began with striking inequalities in the world: more than eight hundred million people in third world countries suffer from hunger, while food abundance in industrialized countries has encouraged over-consumption and unhealthy eating habits (preference for foods high in fat, especially saturated or hydrogenated fats and sweets instead of products based on whole grains, fresh vegetables and fruit) [7]. Analyzing the modern consumer's eating habits we note that it is marked by a series of paradoxes, which will be discussed below.

2. Hazards of food industrialization in the nutritionism era

The scientific and technological innovations accomplished in the last years had a powerful impact on agricultural and food sectors from all over the world. Innovating methods of production revolutionized numerous traditional systems, and also the capacity of producing the food for a continuous increasing population.

Analyzing the predominant foodstuff supply from our days, we see that it has its origins in the industrial period. Also, at that time appeared fast-food, canning and ready meals industries, which have conquered the market, but at the same time, they brought with them the diseases of modern civilization.

Thus, agro-food materials, obtained through extensive use of fertilizers, pesticides, growth hormones and antibiotics, are highly processed, which results in the production of contaminated food that is depleted of its essential nutrients [8].

In addition, the sensorial characteristics of food are not always natural, because of products with artificial taste, aroma, color and texture, due to the use of food additives, the consequence being the extension of a range of goods with an unbalanced nutritional profile

Thus, the gap appears between the exceptional sensory properties of foodstuff and their unbalanced nutritional profiles. Taste, smell, appearance of the product becomes a joke for the body, and since food is more attractive and tasty, the more nutritionally unbalanced and unhealthy is [3].

Intensive industrialization of food has had some negative consequences for society, reflected, in the early XXI century, in the very high incidence of civilization diseases, especially on over consumption (cardiovascular diseases, cancer, obesity, diabetes, cirrhosis, renal failure), which involves huge costs for treatment. These negative consequences were generated by: transformation of whole foods in refined foods, reduction of natural complexity of alimentary products to industrial simplicity, sacrificing food quality for quantity, replacing the landmarks of food culture with the principles of food science.

One of the key features of the modern food is the adoption of foodstuff more and more refined, especially refined carbohydrates. This refinery determines an increase in consumption of "empty" calories per food unit.

There are two ways in which the energy density of refined carbohydrates leads to obesity. First, it increases calories consumption per unit of food. This happens, because dietary fibers, which were removed from refined foodstuff, are those that would give the feeling of satiety, leading to cessation of food intake. When these dietary fibers are missing from the diet, this process is delayed. Secondly, the flow of glucose, which suddenly invading the blood, causes a sudden increase of insulin levels after glucose is assimilated, suddenly fall, creating the sensation of hunger [4].

The problem is that all refined products have empty calories, because it does not contain those micro-nutrients essential for body's biochemistry.

Food Science, supported closely by the food industry has tried to offset these losses by further adding of some of the missing nutrients, in the processing of refined raw materials: vitamins of group B in refined flour, vitamins and minerals to breakfast cereals and bread etc. Even if some of the micro-nutrients lost in processing raw materials are further reinstated, it was proved that food science is not sufficiently advanced that it can offset all the negative effects of whole food processing, because complexity of the whole food is impossible to restore through artificial way.

This conclusion, also ignored for decades, has been highlighted by many researchers since 1930. One of the first remarkable works on this subject was one of Weston Price, a Canadian physician, "Nutrition and Physical Degeneration", published in 1939. Price concluded that modern civilization has largely sacrificed food quality for quantity and the preservation period.

The new nutritionist theory, which treated food merely as simple delivery systems of a single nutrient, emerged in the U.S. at the beginning of the 80s, was agreed by the processed food manufacturers. The term of "nutritionism", created by M. Pollan, is largely pejorative, implying that this way of viewing food is simplistic and harmful.

Although nutritionism proved to be just an ideology, because it was based on a series of unverified assumptions, its basic principle, that of considering foodstuff only the sum of nutrients (different types of fats, carbohydrates, antioxidants, vitamins, minerals, etc.) was adopted immediately with great enthusiasm by the food industry, because it offered the key of an unprecedented diversification range of processed foodstuff. When attention is focused on quantifying the nutrients contained in the food products, it becomes almost seamless the distinction between whole foodstuff and processed foodstuff [9].

What has been ignored both by nutritionism ideology and by the modern food industry was the concept of "food synergy", namely that food is more than the sum of its nutrients.

Using modern modification techniques of raw materials, food industry has brought us into a situation that is the nutritional equivalent of inflation, that means consumer have to eat more to get the same amount of essential nutrients.

Another assumption of nutritionism was that the only purpose of the act of eating is to maintain and improve our health. This assumption has been contradicted by the example of traditional food culture, which showed that people are not less healthy if they see in food something else than a way of satisfying the needs for macro-and micronutrients, highlighting it a social function and an identity one [9].

After a few decades of consumption of over processed foodstuff, based on poor information regarding the health benefits, the balance is sad: people are getting heavier, more sick and underfed.

Thus, we can say that people are trapped in a vicious circle from which they can escape only if they will find nutritional guidelines specific of food culture to which they belong, sent by family education across generations.

3. Paradoxes in the diet of the modern consumer

In general, human history has been marked by uncertainty of food, with periods of relative abundance, alternating with periods of shortage, caused by the combination of crop problems, adverse weather conditions or even political issues. The last two major periods of famine and poverty in Europe between 1712-1742 in France, between 1846-1848 in Ireland, between 1920-1921 in Russia and during the two Great World Wars, between 1914-1918 and 1939-1945. In China, food shortages of the years 1958-1964, linked to social reform movement, resulted in twenty million deaths.

- ***In some countries, food abundance determines the over-consumption while in other countries people are suffering from chronic underfeeding.***

The immediate consequence of this paradox is the increasing number of nutritional diseases, caused by either insufficient or improper food consumption.

Primitive man did not eat much because food was hard to obtain. Contemporary human body has adapted to a certain nutritional level. Excessive quantitative consumption, but unbalanced in terms of quality (preference for fats and sweets at the expense of whole grain and vegetables) are potential sources of disease [2].

In the last decades it can be observed an increase in the number of regions characterized by abundance and food safety. This leads to the disappearance, in those countries considered rich, a many diseases caused by nutritional deficiency, which were still raging in Europe and North America earlier this century [6].

While in Western Europe, North America and parts of Asia there is an excess of food, accessible to everyone, in other countries around the world daily food is a problem. The paradox is that in some countries, food abundance determines the culinary sophistication and waste, while in other countries people are starving.

Worldwide, in developed countries, improved hygiene, nutrition and life has helped to increase life expectancy by almost twenty years, between 1950 and 1990, and to the growth average height of Asian populations.

But when people live longer and begin to consume more and consequently, they have more time available to get sick, and if people are not starving in rich countries, increased longevity has been accompanied by the emergence of the most serious chronic diseases (different forms of cancer, cardiovascular diseases, diabetes, obesity), resulting from a conjunction of physiological, genetic, psychological and environmental factors. Among the last factors, it is widely accepted that nutrition plays a significant role both in triggering and in preventing these diseases. These diseases pose serious public health problems.

Among the causes of these severe degenerative diseases are found the following: abuse of saturated fats and refined sweets, lack of vegetable fiber, vitamins and minerals, which reduces the body's resistance to germs, pollutants and chemical substances or stress conditions. For example, the USA, which is a superpower, where food opportunities are abundant and accessible, 40% of population are overweight and 20% obese. In the USA, treatment of degenerative diseases cost 50 billion dollars, approximately 200 dollars per capita.

If food abundance that characterizes the industrialized countries has led to over-consumption, present situation of over eight hundred million people around the world, who still suffer from diseases caused by chronic malnutrition, has not improved [5].

Unlike developed countries, which face the consequences of an excessive foodstuff offer, developing countries are facing the consequences of insufficient food intake: decay (energy and protein intake too weak), scurvy (vitamin deficiency C9), beriberi (vitamin B1 deficiency), rachitism (calcium

deficiency), anemia (especially iron deficiency), poor eyesight and even blindness (vitamin A deficiency).

Most of these people live in developing countries. African continent is most affected by malnutrition; more than half of Africans live in poverty. In the diet of these countries the proportion of calories from animal food products is less than 5%, while in rich countries exceed 30% or even 40%. This situation is also encountered in developed countries, but the proportion of people affected by food deficiency is less [6].

- ***The pressures of food industry encourage over-consumption, while the canons of fashion require the cult of supple shapes.***

The consequence of this paradoxical situation is the consumer disruption, which loses his nutritional guidelines empirically submitted from generation to generation, in family education.

Consumption society of the third millennium is characterized by a high-availability and accessibility of food, but also by a very strong pressure from the food industry, exercised through the media, to encourage over-consumption. The consumer is faced with contradictory messages: first, incited to consume more and more, under pressure of aggressive advertising, but on the other hand forced to remain slim, by the dictatorship of fashion standards [7].

The current occidental societies are currently marked by a culture of supple forms, without historical precedent.

In the nineteenth century, weight gain in men was associated with health, prosperity and respectability. And for women, some curves and even excess weight were appreciated. In that time is considered that beauty lies mostly in the roundness of forms [1].

At the end of the nineteenth century this perception of the body has been deeply changed. The onset of the twentieth century was marked by the spread of slimming regimes in Western European countries. This dictatorship is still in force.

In societies characterized by food abundance it was developed a real obsession for restrictive regimes, aiming to limit food intake. North American society is the one that has developed, since the early '30s, the

largest number of slimming regimes, some of them being fantasist and even dangerous. Every year, Americans spend tremendous amounts for weight loss clubs, dietetic foodstuff and other dietary remedies that are supposed to favor weight loss.

4. Conclusions

If in general, human history was marked by alternating periods of shortages and relative abundance, in recent decades there is an increasing number of regions characterized by abundant food. However, this abundance of food, that currently characterizes the developed countries, has led to over-consumption and, with it, the loss of nutritional items acquired in family education.

The analysis of alimentary behavior of modern consumer highlights the primacy of quantitative aspects, resulted in high consumption of animal protein and saturated fat, derived especially from refined products, to the detriment of quality, which be could translated by providing the necessary proteins and fats of vegetal origin, micro-and macronutrients and fibers, taken from raw food products. All these led first to a deterioration in the nutritional plan of food, being one of the main factors (along with the genetic, physiological, psychological, environmental) in the onset of serious chronic diseases (cardiovascular diseases, cancer, diabetes, obesity) [10].

Thus, we can say that in developed societies, food based on quantity instead of quality led to a new type of consumer – the individual overfed and malnourished at the same time, two features rarely found in the same body throughout the history of our species [9].

Therefore, now more than ever, the individual must be aware of the links between diet and health and understand the notions promoted along the historical ages, by great thinkers of humanity (for example Hippocrates) and strongly stated by our days nutritionist, namely: "Man is what he eats. "

In the future, people must have an *intelligent alimentation, which emphasize healthy food*. This will be possible only if they'll improve their style of eating through education, communication and information.

Only in this way, in the future, consumer's demands regarding food quality will increase.

Measurements of Local Community Autonomy from the Perspective of Local Public Administration Management

Zaharia Petronela

"Stefan cel Mare" University of Suceava

petronelaz@seap.usv.ro

Abstract

Being the major vehicle of all activities of public administration in territorial-administrative units, local autonomy ensures a high degree of democracy in local community management. But, although this autonomy involves their participation in meeting their own interests, it is limited by the fact that local autonomy does not mean the right of communities to govern themselves in any matter.

Therefore, a proper understanding of this principle is necessary, especially from a practical point of view, in order not to assign an absolute character to the local autonomy and to avoid stressing it.

Key words: public administration, local autonomy, local government management, local communities, local administrative authorities

J.E.L. classification: H83

1. Introduction

Given the current and future requirements imposed by the modernization and reformation of public administration, local autonomy should not remain on paper. Ensuring local autonomy is a present and future reality of local public management, with significant implications for the welfare of the administrative-territorial units, and more importantly, in building an efficient, competent and, last but not least, democratic public administration, which would respond to the needs and demands of communities. In this context, this paper will deal with the local autonomy principle, considering its vital role in meeting the needs of members of the administrative-territorial communities.

2. Conceptual foundations of local autonomy - a basic rule in public administration management

The rules under which local government of administrative-territorial units is organized and functions are formulated by constitutional provisions and the Law on local government. Among these rules is local autonomy as a fundamental principle without which the effective functioning of local government would not be possible.

The definition of this principle is found in Art. 3, Paragraph 1 of Law no. 215/2001 on local public administration which states that "Local self-government denotes the right and effective capacity of local authorities to solve and manage, on behalf of and in the interest of the local communities they represent, the public affairs, under the law." Further, Paragraph 2 of the same article sets the holders of local autonomy, stating that "this right is exercised by local councils and mayors, as well as by county councils and their chairmen, local government authorities elected by universal, equal, direct, secret and freely expressed vote."

Therefore, from the interpretation of the provision above, we notice that in practice, the exercise of local autonomy belongs to local government authorities (mayors and city councils, county councils and their presidents), acting on behalf of the community that have elected them to represent their interests.

Whenever it comes to investigating local autonomy, one should not ignore the fact that it is not only a right but most of all a duty of the representative authorities of local communities who have the mission to manage and solve all the problems of their administrative-territorial unit. In addition, all the rights and duties arising from the content of local autonomy are exercised on behalf of

the local community, as a consequence of the powers given by those who they represent, in other words, only on the basis of the mandate from local voters [1, p. 39].

The above regulations are in line with those existing in this field at European level. Thus, local autonomy is defined for the first time by the European Charter of Local Autonomy, which was adopted in Strasbourg on 15 October 1985 and drafted from the initiative of the Standing Conference of Local and Regional Authorities of Europe, within the Council of Europe.

In the very preamble to the Charter the arguments that led to its adoption are set out, namely that Member States consider that:

- local government authorities is one of the main foundations of any democratic regime;
- the right of citizens to participate in public affairs is part of the democratic principles common to all Member States of the Council;
- at local level, this right can be exercised in the most direct way;
- the existence of public administrative authorities empowered with real responsibilities can provide an effective and close to citizens administration;
- safeguarding and strengthening of local autonomy in different European countries is an important contribution to building a Europe based on the principles of democracy and decentralization of power, this assuming the existence of local public administration authorities, endowed with decision-making bodies, democratically constituted and possessing a wide range in terms of skills, how to exercise them and means to fulfil their mission.

In Article 3, European Charter of Local Autonomy defined local autonomy as "the right and the ability of local authorities to resolve and manage within the law, in their own name and in the interests of local people, an important part of public affairs." According to the Charter, "this right is exercised by councils or assemblies composed of members elected by free, secret, direct and universal vote, which may have executive and deliberative bodies responsible in front of them."

We notice that the rules of the Charter provide a more limited sense to the local autonomy, in that it refers only to "a part of public affairs", unlike the Romanian legislature that seeks to provide a wider sense to autonomy, without limiting the scope of public affairs that local authorities have to manage on behalf of the community whose interests they represent.

But even in such circumstances, no matter how extensive the content of the local autonomy, it is not and cannot be an absolute. Moreover, the Local Government Law itself states that the application of this principle "cannot prejudice the unitary and indivisible character of Romania as a national state" (Article 2, Paragraph 2). Therefore, local autonomy should not impede or affect the character of state sovereignty and national unity of the state, precisely the latter guaranteeing the autonomy of local communities. Being interested in meeting both local interests, as well as the national one, the state creates appropriate conditions for local authorities in the administrative-territorial units at central level to work together to ensure the smooth functioning of the whole society. In other words, the Romanian state recognizes the necessary autonomy for local management of their specific affairs, but only insofar as they are integrated in the legal system of the state [2, p. 149].

3. Local community autonomy from the perspective of local public administration management – forms and dimensions

According to legal provisions, local autonomy is only *administrative* and *financial*, being exerted on the basis and within the limits prescribed by law (Art. 4, Paragraph 1). This provision is likely to curb any tendency or action to distort the exact meaning and content of this principle, to promulgate "local autonomies" on ethnic, linguistic, territorial criteria. [4, p. 352].

Regarded solely administrative, local autonomy does not differ significantly in terms of content from the administrative decentralization. The exercise of local autonomy by the local government is only possible in the context of a decentralized

administrative management, in which the autonomous authorities are elected by the community, and on the other hand, decentralization is what ensures that local authorities provide a wide autonomy, understood as the right to decide on local issues of direct interest to them.

Most opinions expressed in the literature on local government management focus on the nature of local financial autonomy. Lack of financial resources would make it impossible for local authorities to meet the needs of its members, which would lead to failure of the administrative decentralization [5, p. 66].

An effective and efficient local autonomy is possible only where there is financial autonomy. Lack of financial autonomy would make the concept of local autonomy have no content. Satisfying the following conditions ensure the existence of a genuine financial autonomy [3, p. 67]:

- opportunity of the local community to have their own financial resources to cover their scheduled spending;
- freedom of local authorities to determine, in an autonomous manner, their own revenues and expenditures;
- appropriate management information system to link continuous optimal revenue and expenditure;
- local authorities' financial decisions are subject to a posteriori control.

Without the materialization of the financial dimension of autonomy, there cannot be a real self-government. Ensuring effective implementation of local autonomy in managing local government presupposes the existence of financial resources, without which self-management would not be possible and local authorities, representatives of the community, would be unable to complete their mission.

From a practical point of view, local autonomy acquires two forms: *functional* autonomy (technical) and *territorial* autonomy. Functional autonomy entails the recognition of a degree of autonomy for some public work in their field, and territorial autonomy consists in recognizing the right of administrative-territorial units to self-administrate. [2, p. 144]

Regarded from this perspective, local autonomy presupposes that certain conditions are met to ensure this principle, namely the

existence of communities in each administrative-territorial unit, with their own needs distinct from the national community needs; the existence of material and financial resources available to the local community that it can use for self-management; elections by universal, equal, direct, secret and freely expressed vote of the local public administration bodies - holding autonomy - by members of the community; recognition of the plenitude of competence of local authorities in solving problems of direct interest to them; consulting the citizens in solving local problems of special interest as well as the control over the guardianship administration exercised over the activities of the authorities of local administrative units by the central government or its territorial representatives.

The dimensions of local autonomy derive from Article 4, paragraph 2 of Local Government Law according to which "local autonomy regards the organization, operation, powers and duties, as well as the management of resources which, by law, belong to the village, town, municipality or county, as appropriate." From the interpretation of these provisions one has to keep in mind the following dimensions of local autonomy: *organizational*, *functional* and *management* related.

From an organizational perspective, local autonomy is manifested by the eligibility of local public administration authorities. For local autonomy to be possible it is necessary to organize local elections in order to appoint local governing bodies, specific to the local power, without them being subjected to any procedure of confirmation from the authorities at central level. Therefore, the independent character is guaranteed by the fact that the citizens who have the right to vote and who reside in that very administrative-territorial unit designate themselves, without the intervention of other structures, the authorities which will represent their interests. In conclusion, the local administrative bodies - local councils and mayors, county councils and their presidents - administer the affairs of the administrative-territorial units in which they are chosen, serve the interests and ensure compliance with the mandate entrusted by the local electorate.

From the same organisational perspective, we note the relationship between local public administration authorities in villages, towns and cities, on the one hand and local authorities at county level, on the other hand. Between the administrative authorities who serve the interests of local communities there isn't a hierarchical subordination of some over the others, a situation which results without a doubt from the provision of Article 6, paragraph 2 of Law no. 215/2001, which states that "in the relations between local authorities and county council, on the one hand, and between the local council and the mayor, on the other hand, there is no subordination." If such hierarchical relationships between the public authorities at county level and the local elected officials existed, local autonomy would be affected. In this sense, Article 6, paragraph 1 of the Local Government Law provides that "the relations between local public administration authorities in villages, towns and municipalities and public authorities at the county level are based on the principles of autonomy, legality, responsibility, cooperation and solidarity in solving problems throughout the county."

At the functional level, local administrative bodies have the power to solve all of the problems specific to their community, being limited only by issues within the competence of other public authorities. According to Article 5, paragraph 2 of the Local Government Law, "local autonomy gives local authorities the right, under the law, to take initiatives in all areas, except those which are expressly given jurisdiction of other public authorities." This, more so as, local communities know best their needs and interests, and are therefore best in the position to seek and find ways of meeting them.

From a managerial point of view, public authorities of local administrative units are entitled to own property and financial resources in accordance with the principle of ensuring adequate financial compensation correspondent to the competencies and responsibilities incumbent upon them. In this sense, Article 27 of the Public Administration Law provides that "in order to ensure local autonomy, local government authorities have the right to establish and collect local taxes and to develop and

approve the local budgets of communes, towns, municipalities and counties". Article 10 of the same law prescribes that "local authorities administer or decide on financial resources and public or private property of municipalities, cities, municipalities and districts, in accordance with the principle of local autonomy." The communities of local administrative-territorial units hold ownership and administrate buildings, land, different equipment and other miscellaneous goods, plus many financial means they use in the interests of local people. The heritage of each community, its efficient development and capitalisation is, in fact, the main source of prosperity of the inhabitants of each administrative-territorial unit. [1, p. 39]. Without this material support and without the possibility of local authorities to manage it according to the needs of the community, local autonomy would be, from a practical point of view, nothing but an empty principle.

4. Conclusions

In light of the above aspects dealt with in this paper, we can conclude that local government should be based on genuine local autonomy in all aspects: organizational, functional and managerial. The lack of genuine autonomy leads to the impossibility of local authorities to exercise their functions effectively in the service and interest of the people in their administrative-territorial unit. In the virtue of local autonomy, the local government authorities are responsible in front of the citizens who elected them to represent their interests and also decide on making local government work more efficient.

Abstract

The topic of the strategic management of service organizations and its implications on the regional development is highly debated nowadays. Therefore, the aim of this study is to reveal recent research focused on the strategic management of service organizations in the context of the regional development. This study reveals firstly the key factors of the regional development, and secondly some strategic management models for service organizations. Furthermore, new approaches for the strategic management of service organizations in the context of the regional development are emphasized. The findings of this study reveal that there are some changes in the way of thinking about the management of service organizations, which seem to influence the practices in the management of services in a regional context. The findings of this study may be helpful for upcoming research in the area of managing regional service organizations.

Key words: regional development, strategic management, service organizations.

J.E.L. classification: L80, M10, R10.

1. Introduction

This study investigates the core facets of the strategic management of service organizations in the context of the regional development. Firstly, this study reveals the key factors of the regional development, and secondly it highlights some strategic management models for service organizations. Furthermore, new approaches for the strategic management of service organizations in the context of the regional

development are emphasized.

The research was conducted using evidence provided by articles (such as research papers, literature reviews, and conceptual papers) as well as books. The research question was answered by analyzing published sources, and by evaluating and interpreting evidence. Answering the research question was difficult, due to the variety of approaches, concepts, and definitions found in the literature.

2. Key factors of the regional development

The persistent durability of regional successes and failures, as well as of the digital divides, suggest that only the knowledge regions may be good "hosts" to the (networked) knowledge-based economy [1]. Moreover, learning ability and innovations making are considered key factors of the regional development in institutional economics [2]. In this context, universities can have the largest impact on regional economic growth by excelling in advanced research and by augmenting the region's stock of human capital [3]. Under the regional development, the innovative process is more important than innovation production, because it potent the human capital.

Within the knowledge-based economy there is a strong correlation between knowledge, education, information and communication technologies, economic growth and regional development. The new economic growth models are connected to other more dynamic factors, as: human capital, knowledge, innovation and entrepreneurship. Innovation, knowledge and innovation capacity are essential elements in achieving the regional sustainable

development [4]. Geographic position and natural resources are not key concurrence advantages anymore, because knowledge and abilities of employees are becoming key factors for success [5]. Therefore, the key factors of the regional development are: strategic management, information and communication technologies, knowledge, specialized human capital, employees' skills, education, learning ability, research and development, innovation making and entrepreneurship (figure 1).

Figure 1 Key factors of the regional development

The knowledge-based society is characterized by the focus on knowledge, people, and virtual networks. These, as well as the transformations of services determine changes in the way service organizations are managed. We can assert that within the knowledge-based society the management of services is knowledge-driven, it relies on people's continuous development, network-intense collaboration (sharing ideas and knowledge), and value co-creation to attain sustainable competitive advantage.

The interest in studying the specific issues of services and its management emerged (surprisingly or not) among marketing researchers, e.g. [6, 7, 8, 9], who identified managerial implications of the service characteristics and changes. As it was observed in 1994 [10], "researchers interested in services did not predominantly attempt to change old management models and concepts in a marginal fashion in order to fit services. Instead a totally new approach to the problem of how to manage various aspects of service organizations was taken". This approach is what we may call the marketing approach of managerial aspects of services. Furthermore, we may suggest that this marketing approach could be considered

when we attempt to manage service organizations, but it is also needed a rethinking of the managerial concepts and practices in the context of service specificities within the knowledge-based society. This is because from a managerial perspective marketing is only a component of the organization's whole activity, in other words management means much more than marketing, and thus a holistic managerial approach of service organizations may be more suitable within the knowledge-based society in the context of the regional development.

3. Strategic management models for service organizations

A considerable amount of management literature has been published on strategic management, and more specific, various models for the strategic management have been developed [11, 12, 13, 14]. Nevertheless, there is no consensus in the strategic management literature regarding the sequence of activities and phases of strategic management. Although there are differences in the literature, the various models are logically created and include, more or less, phases such as:

- Mission statement;
- Analysis of the external environment;
- Analysis of the company (internal environment);
- Long-term, middle-term and short-term objectives;
- Strategic options;
- Strategy implementation and control.

The LCAG (Learned, Christensen, Andrews, and Guth) strategic management model includes company's external and internal environment analysis, action possibilities, cultural values, strategy identification, implementation and evaluation. It should be mentioned that the company's cultural values integration into the external environment has an indirect impact on the company's strategy [11].

The strategic management model constructed by Pearce and Robinson includes mission statement, company's field of activity, external environment analysis, strategic analysis, global strategy, objectives, functional strategies, policies, strategy

implementation, control and evaluation. We may note the major impact of company's field of activity on the external environment and furthermore, the minor impact of the strategy implementation on the external environment [12].

The strategic management model proposed by Daft is based on the SWOT analysis. The inner component of this model is company's mission statement and objectives redefining, based on strengths, weaknesses, opportunities and threats identification. Founded on the new mission statement and objectives, the company's strategies (global, by activities and functional) are defined and the strategy is implemented [13].

The strategic management model proposed by Rue and Holland comprises the following phases:

- Strategy founding;
- Comparison of the strategy with the previous strategy (if a previous strategy existed);
- Mission statement;
- Long-term objectives identification;
- External environment diagnosis;
- Internal environment diagnosis;
- Strategic alternatives identification;
- Business alternatives identification;
- Strategic alternatives comparison;
- Functional strategies identification;
- Particularities of the organization system;
- Strategy evaluation and control [14].

All these models that have been mentioned above could be applied to service organizations. The main rationale of the strategic management is to set and put into action a global strategy of the service organization (at the level of the organization), having in mind the organization's mission statement and attempting to reach it through the objectives' achievement. Starting from the (different) phases of strategic management found in literature we may assert that within the knowledge-based society a model for the strategic management of service organizations in the context of the regional development may include the following phases:

- Mission statement and corporate social responsibility (CSR);
- Assessment of the company's internal and external knowledge;

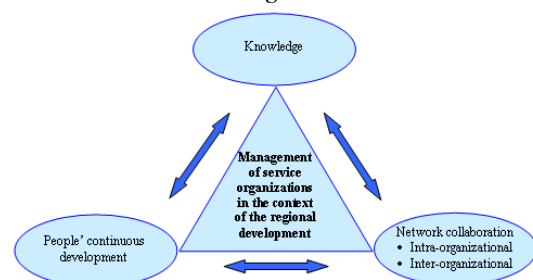

- SWOT analysis (Strengths, Weaknesses, Opportunities, and Threats);
- Mission statement refinement and identification of the long-term organizational and societal objectives;
- Strategic alternatives (options) identification, selection, and communication;
- Strategies (global and functional) identification, selection, and communication;
- Strategic alternatives (options) and strategies (global and functional) refinement;
- Strategy implementation and refinement;
- Strategy evaluation and refinement [15].

We may suggest that the strategic management of services is a process that ought to be reiterated over and over again for service organizations to respond to change (or even to generate it) and to create knowledge for the development of the region in which they work.

4. New approaches of the strategic management of service organizations

In the context of the regional development we can identify some key features of the management of service organizations, namely knowledge, network collaboration (both intra and inter-organizational) and people's continuous development (figure 2).

Figure 2 Key features of the management of service organizations

At the outset, the management of service organizations is knowledge-driven and not customer driven or market driven for two reasons. Firstly, knowledge is the "heart" of society, and implicitly it is the "heart" of all activities, including the management of service organizations. Secondly, knowledge includes, among other things, the criteria for a company's evaluation, which may be internal (such as efficiency or effectiveness)

or external (such as environment or health).

The management of services is a holistic perspective which emphasises network collaboration, both intra-organizational and inter-organizational, since knowledge is created and transferred both within and outside the organization through various networks created at regional level.

The management of service organizations relies on the continuous development of people, which is indispensable for success. There are four arguments for this assertion:

- Besides knowledge, people are the next most important core resource of the management of service organizations which has to evolve on the knowledge spiral;
- People learn throughout their life (lifelong learning);
- Learning may occur inside and/or outside the service organization;
- People could learn traditionally – devoid of electronic devices, as well as through electronic learning (e-learning) or mobile learning (m-learning) – using information and communication technology.

Providing quality services has been identified as one of the most difficult long-term strategies for establishing a business [16]. Today's leading companies operate on a global basis, cooperating with regional suppliers, partners and a multitude of stakeholders, to deliver service and/or product packages [17]. Service providers who understand the needs and interests of clients thoroughly are capable of incorporating customer knowledge into the operation of the organization when enhancing the service intensity. This is not only helpful for the integration of the relationship and input of resources, but also has a positive effect on the improvement of customer satisfaction [18]. Therefore, service quality management may be a key factor for the success of service organizations which operate at regional level.

All these changes in the way of thinking about the management of service organizations seem to influence the practices in the management of services within the knowledge-based society. The managerial objectives, resources, relationships and methods used are all changing. Furthermore, business processes are changing due to the information and communication technology development, and their increasing / widening

acceptance in day-to-day life. The application of information and communication technology in business processes leads to e-business. In a broad sense, e-business currently symbolizes new ways of conducting business, where electronic networks of companies make e-business an inter-organizational activity to a large extent. The performance of the inter-organizational alliance and the ability of the partners to create value in such networks would therefore depend on their relationship competency. With better knowledge of how to influence their business networks, service organizations could increase their influence and their outcome of such relationships [19]. According to [20], "in the virtual plane the effort must be made in the direction of studying those activities that are conductors or generators of value, seeking to support and promote them with a view to sustaining this value creation". However, the same effort is made even though the company provides services in a traditional manner (face-to-face contact with clients). This may be important because traditional business is not excluded by e-business. The distinctive features of the knowledge-based society allow service organizations to generate value in an electronic way that is an alternative, and not an impediment, to business of a "conventional" type [20]. Regardless of the manner of providing services, however, people (employees, clients, partners, and competitors) are connected via open networks (e.g. internet) and management has to take this fact into account.

5. Conclusions

We have emphasized in this study that there are some key factors of the regional development, namely strategic management, information and communication technologies, knowledge, specialized human capital, employees' skills, education, learning ability, research and development, innovation making and entrepreneurship.

Furthermore, this study has revealed some strategic management models for service organizations. On this basis, new approaches for the strategic management of service organizations in the context of the regional development have been emphasized.

This study has shown that there are some changes in the way of thinking about the management of service organizations, which seem to influence the practices in the management of services in a regional context.

The results of this study may be helpful for upcoming research in the area of managing regional service organizations.

Mortgage Loan Negotiating – Applications and Outcomes

Zamfir Cristina-Mihaela
„Ovidius” University of Constanta
cristina_m_zamfir@yahoo.com

Abstract

In business English, certain communicative rules may be extracted by observing behaviour in various contexts and the reactions of the business people community members. In studying language and communication, there is one fundamental approach, i.e. the ethnolinguistic approach. In applying the ethnolinguistic approach to business English, specific categories of vocabulary, types of grammatical constructions, types of sentences and syntactic patterns, types of questions and answers used by business people are studied. In order to clear up such aspects and to further make up statistics, individual speakers (Romanian business people) were interviewed. In this respect, it was very interesting to study the language (concepts, simple words, collocations, set phrases, syntagms, polite formulas, requests) used by the participants in the dialogues.

Key words: business English, mortgage loan, negotiating techniques, polite formulas, banking collocations

J.E.L. classification: F 51, G 21

1. Introduction

In pointing out differences in the way language is used, such factors as gender, age, class, ethnicity, origin have to be considered. In this respect, it should be mentioned that each speaker makes use of the options available in the community. For example, in the businesspeople community, a businessman will have certain options of vocabulary, grammatical constructions, sentence patterns, unlike a businesswoman. The dialogues between a businessman and his interlocutor or a businesswoman and her interlocutor may be illustrative of these aspects. Studying sample dialogues, it will be

obvious that a businessman commonly makes use of certain types of sentences and syntactic patterns when he has to make a deal with a businessman partner, unlike the vocabulary and grammar (the formulas of address and behavioural patterns) when making a deal with a businesswoman. Moreover, “choices in speech style are motivated by many aspects of one’s identity. Sociolinguistic studies consider the ways that specific attributes influence a speaker’s selection in any given situation” [1].

2. Mortgage Loan Negotiating

STEP 1: WELCOMING THE CUSTOMER

Manager: Good afternoon. How can I help you?

Client: I am interested in getting a loan from you.

STEP 2: IDENTIFYING THE CUSTOMER’S NEEDS

Manager: Due to the fact that we have several options, may I ask you some questions in order to find out which of our products suits you best? How do you intend to use the money? I mean for what purpose?

Client: I need an amount of money to buy a house.

Manager: How much money do you need?

Client: EUR 40,000.

Manager: I suppose you are interested in buying an apartment.

Client: Not an apartment, only a studio apartment.

STEP 3: OFFERING CONSULTANCY

Manager: As you are young, our bank can offer you a mortgage loan on a maximum period of time of 30 years, which means that

you are supposed to pay smaller monthly installments.

Client: Smaller installments? So, what you are telling me is that, due to the fact that I am younger, I will have the possibility to pay back for a period of 30 years, but I could also repay the amount in advance, couldn't I?

Manager: Yes, you can make partial or total advance repayments. Your advantage is that the bank will not charge you any fee for advance repayment and you will no longer pay the interest corresponding to the installments paid in advance.

Client: What interest will I have to pay for this loan?

Manager: The good news is that we have just launched a new mortgage loan product with a fixed interest of 8.0% until January 1st 2011. After this date, the interest will be variable. How does that sound to you?

Client: It sounds interesting! I have also been to other banks and the interest was higher.

Manager: Should I give you any other details about the loan?

Client: Yes, please.

Manager: The loan we are offering you involves reduced costs: a granting fee and an annual administration fee. Do you have any other loans?

Client: One single loan of personal needs.

Manager: We can refund that loan. So there will be a bigger loan and you will have to pay only one monthly installment.

Client: What is the security of the loan?

Manager: The security is the very studio apartment you will buy by means of this loan. The bank mortgages what you buy.

Client: And yet, will there be any other loan related costs?

Manager: Yes, you will have to pay the mortgage protection insurance besides the life insurance.

Client: What amount are we talking about?

Manager: Life insurance is made for a loan exceeding EUR 25,000 and it is made for an amount equal to 20% of the loan value valid for the entire loan period. The real estate insurance will be paid by you in monthly installments that are added to the loan's installments.

May I ask you other questions as well?

Client: Of course.

Manager: What is your monthly income and what is the seniority at your last employment?

Client: I earn RON 3,000 per month, and I have been working for the same company for 2 years.

Manager: Based on your information and according to a prescoring, you can be granted EUR 42,000 for a period of 30 years. In financial terms, you are an eligible customer for our bank.

Client: Then, may I be absolutely certain of getting the amount of EUR 40,000 that I need?

Manager: That's right. Besides, I must tell you that you will need a down payment from your own sources amounting to 15% of the investment's value.

Client: When am I supposed to pay this down payment?

Manager: You have to pay this down payment by a pre-agreement at the notary public or at the real estate agency before the approval of the loan.

STEP 4: CLOSING / FOLLOW UP

Manager: I see you have some doubts. How can I help you?

Client: I find this real estate mortgage a little risky. If I cannot pay, is my house supposed to be taken away?

Manager: I can understand your concern. Under no circumstances will the bank take away your house on the first delay. Besides, you will receive a notification at home in case you delay paying the installment. This way, you will know for sure what the period of delay is and the amount you have to pay. Bear in mind that after 3 consecutive non payments, the bank may start the forced execution procedure.

Client: I wish I didn't have any problems and could pay all the debts to the bank. May I also get an amount of money for fitting up the house?

Manager: For fitting up the house we can offer you a credit card loan with an advantageous interest.

Client: Yes, let me think about your offer. May I have your business card, please?

Manager: Of course, here you are (she offers her business card to the client). Have a nice day. I will be waiting for you to fill in the forms together.

Client: Thank you. Good bye.

3. Analysis and Comments

Mortgage loan negotiation

Step 1: Welcoming the customer

At the beginning of the conversation, the manager takes a positive, direct approach to the potential customer, greeting her warmly and friendly. Linguistically, the manager uses the open question "How can I help you?" placing herself at her client's disposal.

Step 2: Identifying the client's needs

The second step, i.e. identifying the client's needs, concentrates on asking those types of questions which allow for a complete understanding of the client's financial needs. The manager uses the *technique of informing* the client of the various alternatives that the bank can offer, wanting to identify, together with the customer, that specific product which seems to correspond best to the needs of the customer. The manager uses simple and direct language like "Due to the fact that we have several options", addressing her client in a polite way by using the verb *allow*: „allow me to ask you a few questions in order to find out which of our products suits you best". In this respect, the open question „For what purpose do you intend to use the money?" is likely to gather information and explore the interlocutor's buying intention. Once the intention has been identified, the manager addresses a closed question in order to ask for precise information: „How much money do you need?" Following the client's short answer indicating the amount of money she wants to borrow, the manager uses the presupposition „I suppose you are interested in buying an apartment". Her guess about the client's intention is not entirely correct and the customer comes with the clarifying statement „Not an apartment, only a studio apartment".

Step 3: Offering consultancy

The manager shows the advantages of the mortgage loan offer. To attract the customer, she engages in a conversation based on what

specialists in the field of selling call *characteristics – benefits* presentation. Thus, she shows the way in which the characteristics of the offer result in benefits to the client. From a linguistic point of view, the advantage is expressed through the linking phrase *which means that*: „Our bank can offer you a mortgage loan on a maximum period of time of 30 years, because you are a young person, *which means that* you will pay smaller monthly installments". The customer's positive reaction immediately signals a real interest in the offer by the use of the repetition „smaller installments?". In negotiating terms, the language structures that she uses, i.e. „So what you are telling me is that, due to the fact that I am younger, I will have the possibility to pay on 30 years" stand for the *checking understanding* and *summarizing techniques*. She uses the manager's words and goes over the points already covered to make sure that she understands correctly. She ends her statement by using the tag question „couldn't I?" inviting the hearer to respond to the statement affirmatively. The client's negative tag question expects a *Yes* answer. It has a falling tone whose „translation" might be „I know that what I said is true, so please agree with me!". The manager strengthens the client's belief with a firm „Yes" followed by detailed explanations. These are connected by the linking phrase *your advantage is that* which combines two benefits linked by the subordinating conjunction *and*: „Your advantage is that the bank will not charge you any fee for advance repayment and you will no longer pay the interest corresponding to the installments paid in advance". Both the manager and the customer match sensory predicates by using the verb *sound*, a verb belonging to the auditory system of representation: „How does that *sound* to you?" and „It *sounds* interesting!" The manager uses two types of information. On the one hand, what is usually called *given* information, is placed at the beginning of the sentence, and, on the other hand, *new* information which normally goes at the end of the sentence. In the dialogue, the given information is represented by the loan itself which the client is already familiarized with from her discussion with the manager, whereas the new information is introduced

with the purpose of favourably presenting the advantages of the loan:

GIVEN	NEW
The loan we are offering you	involves reduced costs, respectively a granting fee and an annual administration fee.

As it can be clearly seen, the new information is introduced by the verb in the present tense simple „involves” followed by the advantage „reduced costs” further divided into „a granting fee” and „an annual administration fee”. This clause sends a message which contains a theme and a rheme. According to Katan (2004:154) [2], „In English, the theme is at the beginning of the clause and normally coincides with *given* information”. Wolfgang Dressler (1992) [3] also considers that English respects the *ordo naturalis*, i.e. starting with the given information and continuing with the new information. Torsello (1992:152, 153) [4] insists on the role of given and new information concluding that „It is the assignment of given and new which serves primarily to relate the stretch of text to what has gone before in the text”.

In my analysis of the conversation, I found many set phrases, most of them collocations relating to the field of banking such as:

Phrase	Meaning in English for Banking
<i>get a loan</i>	borrow money from the bank in order to buy a property
<i>An amount of money</i>	a sum of money that someone borrows
<i>mortgage loan</i>	a loan to buy a property; a legal arrangement where you borrow money from a financial institution in order to buy land or a house, and you pay back the money over a period of years.
<i>monthly installments</i>	a series of regular payments that are made until all of an agreed amount has been paid.
<i>repay an amount</i>	to pay back money that has been borrowed.
<i>partial repayment; total repayment</i>	a payment that is part of the total payment for something; the final amount of payments

	when everything has been counted.
<i>charge a fee</i>	to ask someone to pay a particular amount of money for something.
<i>advance repayment</i>	a payment made before a loan is completed.
<i>interest</i>	an amount paid by a borrower to a lender, for example to a bank by someone borrowing money for a loan.
<i>refund a loan</i>	to replace one loan with another one, usually at a lower rate of interest.
<i>security</i>	property or other assets that you promise to give someone if you cannot pay back the money that you owe them.
<i>mortgage insurance protection</i>	insurance against not being able to make repayments on a mortgage.
<i>life insurance</i>	insurance that pays out an amount when someone dies, or, with an endowment policy, when someone reaches a particular age or dies.
<i>income</i>	money that you earn from your job or that you receive from investments.
<i>seniority</i>	the official advantage someone has because they have worked for an organization for a long time.
<i>prescoring</i>	an economic calculation to find out if someone can be granted a credit.
<i>Grant an amount of money</i>	a sum of money given to a person for a particular purpose.
<i>eligible customer</i>	a customer allowed to do something or receive something.
<i>down payment</i>	a first payment made in the repayment of a large debt, such as a mortgage.
<i>pre-agreement</i>	a formal agreement which contains the main ideas or parts but not all the details.
<i>notification</i>	a formal document warning someone about something or asking them to do something.
<i>pay the debts</i>	to give a financial institution (the bank) the money you owe them.

<i>credit card loan</i>	money borrowed by using a credit card.
<i>fill in the forms</i>	to complete an official document by adding information.

There are also linking words which join ideas within a sentence or between sentences like: *because, due to the fact that, yet, but, in order to, in this case*, an inversion after the negative adverbial *under no circumstances*: „Under no circumstances will the bank take your house on the first delay”.

Step 4: Closing/Follow-up

The follow up stage is also accompanied by another business proposal: *For fitting up the house I can offer you a credit card loan with an advantageous interest*. This kind of phrase known as **hook phrase** is very useful as a selling strategy to attract and determine the customer to also buy a new product, other than the one he has originally agreed on.

4. Conclusions

The essential element in the sociolinguistic approach is the context itself with its components: environment, participants, topics and goals, all of them influencing speech. This approach may be obviously applied to business English. For example, the first component, i.e. the *business*

environment is as important as the other components, i.e. participants, topics and goals. By way of illustration, I considered the following situation: a mortgage loan negotiation in a big bank. When a bank clerk has to negotiate the loan with a potential customer, he has to apply the modelling technique. He should be sensitive to contextual cues and adjust his speech accordingly. In order to illustrate these aspects I made up certain statistics and a number of linguistic inquires, besides other (experimental and) situational observations and analyses.

The Timelining Technique and Its Linguistic Expression in Business English

Zamfir Cristina-Mihaela
"Ovidius" University of Constanta
cristina_m_zamfir@yahoo.com

Abstract

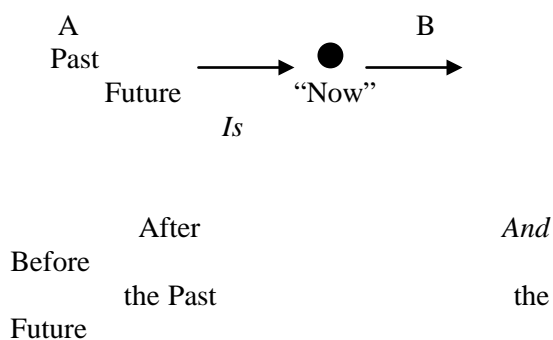

The present paper deals with the concept of timeline as a perceptual filter. This has been interpreted as an essential principle in forming our unique representation of the world. Measuring *time as motion* has made leaders aware of how *time as an entity* can exert a strong influence on the dynamics of business. The notion of timeline draws on the *in and through time dichotomy*. From this point of view, language contains a constellation of idioms. People usually express their preference for either the "through time" or the "in time" in their linguistic use of certain *phrasal verbs, adjectives, idiomatic phrases*, as well as critical *submodalities*.

Key words: timeline, in and through time dichotomy, Anglo-European business, idiomatic phrases, submodalities

J.E.L. classification: A 29

1. Introduction

The concept of timeline as a perceptual filter has been interpreted as an essential principle in forming our unique representation of the world. For many centuries, scientists and philosophers, starting from Aristotle to Einstein and Freud, considered the influence of time on the way people give meaning to an experience. From Aristotle's point of view, time resembles a *point in motion* along a line, an approach which is very similar to the modern concept of time in today's business life. His view of time as "points" on "lengths" of a line in such a way that "now" is "after" the past (A) and "before" the future (B) matches the leaders' use of motion to conceptualize time into their experiences.

(Source: Dilts and DeLozier 2000:1425) [1]

In other words, time perception or *time coding* as motion has come to represent the primary mode of thinking and the best way of planning future actions in Western societies. That is why, measuring *time as motion* has made leaders and managers aware of how *time as an entity* can exert a strong influence on the dynamics of business.

Our internal perception of time greatly affects our recalling of past experiences, the importance of "now" events, and the planning of future objectives.

The Webster's Dictionary (1996:1485) defines time as "a non-spatial continuum that is measured in terms of events that succeed one another from past through present to future" [2], certifying that events are chronologically arranged on a continuum, extending from left to right, with the *present* being somewhere in the middle.

The *timeline* continuum has been a major preoccupation for many researchers. Significant explorations have been made by theorists into the way people represent time subjectively, starting with Richard Bandler (1987) and continuing with Tad James and Wyatt Woodsmall (1988) in their book *Time Line Therapy and the Basis of Personality*. Moreover, James and Woodsmall's notable contributions to the notions of the "*in time*" and "*through time*" *time lines* [3] revealed

the way in which our memories are sorted and stored by the brain. James and Woodsmall's two basic timeline perspectives, namely *through time* and *in time*, are a reflection of how people choose to live their life.

Tad James describes these two main types of timelines. The first, i.e. the "through time", is also called the Anglo-European type of time, and includes the past on one side, the future on another and both are visible in front of the person. The second type he calls "in time", or Arabic time, where the timeline stretches from front to back so that one part (usually the past) is behind you, and invisible.

Traditionally, we refer to two broad types of time awareness and timelines. Once you are aware of your timeline and are flexible about how you use it, you can choose what activities you use each type for. A summary of some generalizations about in time and through time differences was made by O'Connor and Seymour (2002) and O'Connor (2001):

Through Time
Anglo-European type of time
Western
Left to right
Past/present/future
Memories usually dissociated
Time schedules important

In Time
Arabic time
Eastern
Back to front
Time happens now
Usually associated memories
Time schedules not so important

Source: O'Connor and Seymour (2002)

Through Time
Your time line passes outside your body
You are dissociated from the now
You tend to have dissociated memories
You tend to plan ahead
You are aware of deadlines and are good at keeping them

In Time

Your time line goes through your body
You are associated in the now
You tend to have associated memories
You tend not to plan
You avoid deadlines or are not good at keeping them

Source: O'Connor (2001)

A study which taps into Molden's conceptualization of time examines the correlation between time and leadership. It draws on the ***in and through time dichotomy*** which explains the concept of time management. The notion of timeline, seen as a useful technique, is relevant to the way we do business today. In an increasingly competitive environment, leaders must keep up the pace and rethink time coding as a perceptual filter. In other words, they will need to mastermind their projects in relation to time. From this point of view, language contains a constellation of idioms that stem from the metaphorical use of the notion of time:

e.g. ***We have all the time in the world for preparing a good advertising campaign.*** (time is at our disposal and we can own it)

Now that her boss is abroad, she has too much time on her hands. (time is possession)

You can't make time to listen to all the applicants. (time as something we manufacture)

The team were racing/battling against time to finish the report by Thursday. (time has physical form, time is enemy)

Time is on their side. (time is partial to them)

Time is a great healer/heals all wounds. (time is cure)

Time is of the essence. (time allows you to take quick action)

There's never enough time. (time is a commodity which is always in short supply).

The time is ripe for an investment in American real estate. (time is opportunity)

We invest a great amount of time in mergers and acquisitions. (invest time – time as a unit of currency)

Timelines are important to a person's sense of reality. Ways of talking about events are likely to program how we represent them in our minds.

2. 'Through time' timeline

The first time configuration, i.e. people with a *through time pattern*, characterizes those with a high value on time, even having an obsession with time by planning and scheduling every task easily. Due to their "v-shaped through time" timeline (see Figure 1 below), they are more likely to "use complex personal organizer systems because the past and future have as much importance as the now" (Molden 1996:42) [4].

Fig.1 Through time timeline
(Source: Molden 1996:43)

It should be pointed out that the distinction regarding *through time* people contrasted with *in time* people is that the timeline of the first ones does not pass through their body, but it is in front of them. They pay equal importance to past, present and future events. That is why their *memories* are usually *dissociated*: they are fully aware of time, recording exactly what they have done lately, what they are doing now, and what they will be doing in the future.

According to Dilts and DeLozier (2000:1422), "When one perceives an event 'through time', one takes a vantage point that is outside of the sequence of events, disassociated from whatever is being observed or modeled. Perceiving an event 'through time' involves **being disassociated from the immediate moment and seeing its relationship to past and future**".

In business, planning is more like a 'through time' activity because of the sequence of events that it presupposes, and the way this sequence progresses in time. The *through time* perspective helps a businessman keep sight of the whole in making quantitative analyses, for instance. As Bradbury (2006:73) puts it, "Someone in 'outside time' mode 'sees' events as

something like a stream flowing past in front of them. They are better able to *view the past* and *plan ahead* and thus see how events are developing"[5]. People with a 'through time' pattern are usually involved in operations like production and work from traditional linear timelines.

This kind of timeline has a practical application in management being mostly suited to the *Anglo-European business* where businesspeople are *dissociated from the present* and *associated with their schedule*, and for whom *Time is money*. O'Connor and Seymour (2002:137) pointed out the sequence and linearity of time from the point of view of a 'through time' person, stating that, in the Anglo-European type of time, "the timeline goes from side to side" and that "This is the time that is prevalent in the business world"[6]. This perspective is also shared by O'Connor (2001:109) who mentions that "In Western cultures, the past is often on the left and the future on the right because of the standard language reading sequence and accessing cues"[7].

3. 'In time' timeline

The second time configuration, i.e. people with an *in time style*, represents those people who are more concerned with the content of an activity, with *how* something should be done rather than what is to be done. Metaphorically speaking, this timeline "actually **cuts through the body at the present**" (Molden 2001:156) [8], making people receptive to the task in hand, and hence, more associated with time (see Figure 2):

Fig. 2 In time timeline

(Source: Molden 2001:157)

Compared to the *through time* people, the *in time* people unconsciously ignore time schedules and are more flexible with time since, for them, there is no such thing as

the present moment. So deadlines, business appointments and time-keeping are less important than they are for a through time person. In the *Arabic time*, as it is frequently called, business deadlines are more flexible than in the Western world, business people leave the past behind and the future is looked on "like a series of nows" (O'Connor and Seymour 2002:138).

In Dilts and DeLozier's (2000:536) view, "being 'in-time' refers to being 'in the moment'". Perceiving an event 'in time' involves **taking a vantage point associated within the event that is unfolding**". Thus, from an *in time* perspective, one can view **the non-linear temporal relationship of past and future as frames which influence ongoing experiences**. In the business environment, those who run an 'in time' timeline are more recommended for jobs in Research and Development because they show a talent for creative work and are tempted to perceive time more non-linearly. They are likely to view the timing of a project more like the assembly of a "jigsaw puzzle". The elements "fell into place" when enough other pieces had been assembled and the "time was right". Upper level managers tended to perceive time more in terms of cycles and pie charts, representing relative amounts of time measured with respect to one another.

In my opinion, the two perspectives, i.e. *in time* and *through time* could be described in terms of *active* and *passive*. Thus, on the one hand, an *in time perspective* is more *active* because the person who displays this style can easily get *associated* into the past and into the future, acting as if it were happening 'in the moment'. On the other hand, the *through time perspective* is more *passive* because it is more *dissociated* (disconnected) from the immediate moment and the emotion attached to it, and so are the internal representations and accompanying physiology.

4. The language of the timeline

People usually express their preference for either the "through time" or the "in time" in their linguistic use of certain words and phrases. Sometimes our language can suggest a lot about the ways in which we habitually relate to time, when we use phrases such as:

- looking *forward* to something
- putting something *behind* you
- looking a long way *ahead*
- leaving issues *to one side*.

These phrases can be coordinated as well with specific body language cues. The structure of these expressions may be:

- *let's + verb + object + particle* (an adverb or preposition) + *pronoun* as a way of making a suggestion for the speaker and hearer to do something:

e.g. (1) *Let's put that behind us* (gesturing backwards).

- *let's + verb + object + particle*:

e.g. (2) *Let's set that aside* (pointing to one side).

- *let's + verb + 2 particles + pronoun*

e.g. (3) *Let's move forward on this* (pointing forward).

- "let" in its imperative form with the meaning "allow" (allow me to...)

e.g. (4) *Let me get a clearer picture of what is to be done* (unfolding his/her arms out in front).

It should be pointed out that sentences (1) and (2) indicate a *through time* perspective through the use of the phrasal verbs *put behind* and *set aside*, whereas the phrasal verb *move forward on* in (3) and the idiomatic phrase *get a clearer picture* in (4) illustrate the *in time* timeline.

Besides the previous pattern *let's + phrasal verb*, there are also *adverbs* and *prepositions* which are likely to put an action in time: *before*, *during*, *after*, *until*, *by*, *when*, *previously*, *simultaneously*, *subsequently*:

e.g. **Before** you talk to the customer, I need you to check up on this with me.

After you talk to the customer, I need you to check up on this with me.

Before you talk to the customer, but **after** you have introduced the database in the computer, I need you to check up on this with me.

Through their positioning at the beginning or in the middle of the sentence, *before* and *after* introduce subordinate clauses and become subordinating conjunctions whose function is to indicate which event happened first. The *earlier time* is suggested by *before*, and the *later time* by *after* (Leech, Cruickshank & Ivanič 2001:29-30, 99)[9].

The arrangement of events which create a certain mental space can affect us. According to O'Connor (2001:113), "These prepositions

position us in time and affect our experience". Another perspective for analyzing time language is by paying attention to how people give different **submodalities** to events. As O'Connor puts it, "You can find out a lot about how people think about time together with their critical submodalities by listening to their language" (O'Connor 2001:112). People may change submodalities in relation to distant/ recent past or near / distant future:

e.g. (1) *It happened in the dim and distant past.*

(2) *The small company faces a bleak future.*

(3) *The leader's looking forward to receiving a huge payoff.*

(4) *Put this failure behind you.*

(5) *Time is running out.*

(6) *Time is on our side.*

The verb *happened* refers to the past time frame, the verb *faces* in the present tense makes reference to the present time frame, and the phrasal verb *is looking forward* has a future meaning. The adjectives *dim* and *bleak* and the phrasal verb *looking forward* are critical submodalities for the visual system of representation, while the phrasal verb *running out* and the prepositional phrase *on our side* correspond to the kinesthetic representational channel.

5. Conclusions

Whether we treat such language as metaphorical or as reflecting distinct neural patterns, it provides a useful model for understanding subjective experience and personal change and communication. Just as with sensory predicates, time predicates can seem strange to a person with different internal strategies or preferences. They give us an insight into another person's map of the world.

Although we all have a timeline, it may differ from another person's. We store and recall memories in a very different way, create our own map of reality, and thus change the very meaning of time. When we identify our own timeline, we will understand better how we 'code' time.

Persons with Disabilities and Employment

Zodieriu Elena

„Alexandru Ioan Cuza” University of Iasi

elena_zodieriu@yahoo.com

Abstract

People with disabilities represent an important social category inadequate used on the labor market in Romania, which generates losses for both labor market and for these people who are isolated and forced to live in poverty.

Many employers are reluctant to hire such a person, even where the law requires it when the employers exceed 50, and prefer to pay the amounts required by the state. Although there is much work for these people, however the number of hiring people with disabilities remains quite small, due to the fact that employers must invest in job accessibility, which means additional costs for the employers.

Key words: disabled person, protected unit, quota system, employment accessibility.

J.E.L. classification: J 14

1. Disability

The social disadvantage resulting from the loss or limitation of opportunities – because of the existence of an impairment or disability – to take part in the community life in a level equivalent to other members.

The disability comprises a number of functional limitations that may be encountered in any population of any country in the world. Disability describes the interaction between the person with disability and the environment. This term (Standard Rules, 1993) is to focus attention on the shortcomings in the environment and actions organized by the society, such as information, communication and education, which prevents people with disabilities to participate on equal terms. The term disability first appeared in English. Beginnings are identified in the XVI th century, in an equivalent gamble with lottery today. Later

the term is used to evaluate differences in racing performance of horses. Conțiu Șoitu apud. Rusu first identifies current uses of the term with meaning at the end of fourth decade of the XX th century in the form of "physical disability".

People with disabilities are considered high risk social categories with multiple social exclusions. Thus the consequences of disability are reflected on several levels: on an individual level by limiting opportunities and social integration of those affected to have access to the resources of society, on the family level by taking care of the family, especially by women in the family by reducing family income, labor market participation, which increases the risk of reaching families in poverty and through the stigma faced by the family of the other, on the community level we are dealing, first with increased risk of poverty in the community and on the other side with possible tensions caused by the stigma associated with disability, and not least the effects are visible in society economically, in the labor market by decreasing the number of persons employed and growth number of those assisted.

In 1993, the United Nations adopted the Standard Rules on the Equalization of Opportunities for Persons with Disabilities, along with an action plan, and recently launched a powerful new legal instrument - the Convention on the Rights of Persons with Disabilities, adopted in 2006. The Convention stipulates the right of persons with disabilities to earn a living through work, which is their choice and freely accepts the principles of equal opportunity, equal treatment and non-discrimination, and ensures this human right by law. At the same time, there is forbidden any discrimination based on disability for any form of employment and provides protection for those who acquire a disability during employment through measures relating to job

retention, vocational and professional recovery, where appropriate, return to work. The Council of Europe with the Malaga Declaration in 2003 and the Action Plan 2006-2015 have the same purpose.

In 2005, NAPH has developed a national strategy for protection, integration and social inclusion of persons with disabilities for the period 2006-2013 "Equal opportunities for people with disabilities - towards a society without discrimination." This strategy aims to shift from a passive policy, creating opportunities for the development of an active policy (notably to increase coverage of people with disabilities in educational and training services). An active policy requires rethinking the kinds of institutions and social services through diversification and increased participation of the NGO sector in the provision of complementary services (Preda et al., 2006).

In December 2006 it was promulgated the law 448/2006 on the protection and promotion of the Rights of Persons with Disabilities, which is in agreement with the European documents on the matter. One way that a person can integrate is the social engagement or participation in the labor market. A low degree of engagement of persons with disabilities is recognized both at national and European level (Commission of the European Communities, 2007). Current legislation (Law 448/2006) provides measures to encourage employment of persons with disabilities by establishing a rate of 4% for firms with fewer than 50 employees, tax incentives and protected forms of employment (sheltered workshops, protected units) which also benefit from tax breaks.

2. Employment systems for persons with disabilities

The most common system for the employment of persons with disabilities is the form of quota. The share is the obligation of employers that a certain percentage of staff are persons with disabilities, an obligation imposed on both public sector employers and the private sector, especially those who are over a certain number of employees.

The quota system was developed after First World War, Germany being among the first countries to have introduced such provisions (1922), followed by most European countries. Most often, compliance with those obligations attract financial penalties on employers, and funds raised are used for rehabilitation services or socio-professional reintegration for persons with disabilities. This system is based on the fact that without the obligation prescribed by law for employers, they will not hire people with disabilities because of low productivity and people with disabilities cannot compete with free labor.

These assumptions have been criticized by activist movement of persons with disabilities, and the quota system was considered stigmatized because it focuses on the idea of disability and dependence. Activist movement promoted the concept of civil rights for people with disabilities and non-discrimination policies and structured in the U.S. and later in Britain. This approach considers that people with disabilities can compete equally in the labor market with the condition that the social environment should not create barriers, while rejecting such positive discrimination quota programs.

The quota system was retained in many countries, particularly those such as Germany, where national constitutions emphasize positive rights. OECD (2003) notes that the choice between the anti-discrimination model and the quota model is based on quota rather cultural and attitudinal differences. Thus, in Anglo-Saxon and Scandinavian countries, the obligation bound by the central level (quota system) is not considered suitable or effective, while in continental Europe such policies are well defined.

In Romania, the quota system was introduced by the Law nr.57/1992 that requires employers with over 250 employees have at least 3% of disabled staff. If this condition is not fulfilled, the penalty was a minimum gross salary multiplied by the number of unfilled vacancies. Subsequent amendments have expanded the scope of law firms including more than 100 employees, and later with more than 50 employees. Also, the percentage required of employees with disabilities increased from 4%, but sanctions were dropped, now being 50% of national

gross minimum wage multiplied by the number of unfilled vacancies. It has been taken into account the possibility of firms to purchase goods or services in the amount due from authorized protected units. If the initial penalties paid by employers were paid into a special fund used to finance various programs to assist people with disabilities, currently they are transferred to the general budget.

In 2000, the EU protected units where worked around 500,000 people with disabilities but there are significant differences between countries in terms of employment in the open market vs. protected units. Sweden and France have chosen to subsidize the employment of persons with disabilities; the Netherlands and Poland are the countries that have developed particular segregated employment programs, protected units employing about 1% of the total working age population. Norway is the only country where the transition rate is significant - over 30%. In Ireland, where the units are an important form of protected employment in number of beneficiaries and the amounts allocated from public funds, efforts were made to improve the rate of transition by imposing maximum period a person can work in a protected unit and to put a greater emphasis on training component. Similarly, in Netherlands it was encouraged the establishment of protected places under ordinary companies. Even so, the rate of transition to the open labor market remains under 10% in Ireland and less than 4% in the Netherlands.

3. Integrating people with disabilities in economic and social life

Current legislation provides that the disabled person can work on the free market in units or sheltered workshops and at home. Supported employment is considered to be (CEC, 2007) an insufficient means used to support the employment of people with disabilities. This involves providing coaching and workplace adjustments on the open market to meet the needs of the disabled person. In Romania, this form of support was introduced in the new legislation in 2007, being used mainly by NGOs.

In 2010, in Romania there were about 400 units protected. However, the number of people with disabilities working in protected units is very small. Thus only 1% of all employees with disabilities work in protected units, the rest of them being employed on the open labor market. In Romania, the unit system has grown weak, being absent significant incentives offered to compensate for any loss of competitiveness. The protected units work, in most cases, only as a secondary labor market. There isn't an obligation for the protected units to develop related training or rehabilitation services; these are offered only by some units which have acquired the protected target voluntarily, especially those affiliated organizations of persons with disabilities.

According to Article 44, the Order 60/2007 - are considered protected units, entities with or without legal personality, under which they operate persons with disabilities, in these conditions in the legal sense:

- economic operators with legal personality, regardless of ownership and organization, with at least 30% of the total number of employed persons with disabilities assigned to individual employment contract;
- sections, workshops or other structures of economic operators, public institutions or nongovernmental organizations, which have their own management and at least 30% of the total number of employees employed and paid by persons with disabilities;
- physically disabled person authorized by law to carry out independent economic activities, including familial association with at least a person with disabilities. This includes individuals with disabilities authorized under special laws, operating both individually and in one of the forms of occupation.

Authorized protected units have the following rights: exemption from paying the establishment and renewal authorization, exemption from income tax, provided that at least 75% obtained relief fund to be reinvested for restructuring or for the purchase of technological equipment or creating protected jobs and other rights granted by local authorities financed from their own funds.

Licensing and implicit recognition of protected units began in 2003. Although in recent years their number has even increased by more than 50% in one year (2008 to 2007) they are still very few compared to the number of people with disabilities who could benefit from employment. In comparison, in the U.S., the employment rate of people with disabilities of 16-64 years was around 20% to 65% of the general population and the unemployment rate of 14% compared to 8.7% of the general population (U.S. Bureau of Labor, 2009). The European level shows that women with disabilities participate in the labor market to a lower extent than those without disabilities (CEC, 2007).

In both the European Union and the United States, people with disabilities have a lower employment rate than those without disabilities, but there are wide variations between countries. In the EU, about 50% of people with disabilities have a job. OECD estimates that in the Nordic countries the employment rate reached 52-54% (Sweden, Finland and Switzerland), 50% in Luxembourg and 40-45% in Norway, Britain and the Netherlands. In Ireland less than a third of people with disabilities have a job, while in Poland the percentage is lower than 20%. In France between 50 and 70% of people with disabilities have a job. There, all the companies that have up to 20 employees are required to have 6% of employees with disabilities. In Romania, this binding occurs only at firms with over 50 employees, and the percentage is only 4 people with disabilities.

If they don't meet this requirement, employers are obliged to turn to the budget half of the minimum wage for each position to be filled by a person with disabilities. In Romania, the employment rate of persons with disabilities is significantly lower compared with the general population. Only 12.7% of disabled people aged 18-55 years have a job, while the employment rate in the general population sample of the same age is 70%. Lately, the employment rate of disabled people has doubled in the period 2003- 2009, and in absolute terms the number of people with disabilities who have a job has increased 3 times.

Currently the number of disabled employees is about 29,000 in total, including those working in small firms under 50

employees and in sheltered workshops. If we consider that all these people would be employed in the quota system, which does not conform to reality, it follows a reserved seat-occupancy rate of 15% quota system, however well below other countries with system rate.

However, the employment rate of people with disabilities remains one of the lowest in Europe. The participation of persons with disabilities in society is one of the objectives of the Convention and the European regulations in the field of disability. Accessible access routes in public places, the premises of establishments are a way to facilitate the growth of their social participation. In general, any job can be adapted to the specific needs of persons with disabilities. To streamline this process is desirable to identify the best match between job description and skills requirements of the disabled person.

Recently there were developed standards for airport accessibility for people with disabilities in accordance with Regulation (EC) no. 1107/2006 of the European Parliament and the Council on rights of disabled persons and persons with reduced mobility when traveling by air. In Romania, by law, employed persons with disabilities (severe and bold) are exempt from income tax. Thus employers can deduct from their taxable profits for the money spent to adapt the job to transport the disabled person at work. Training expenses for the disabled person may be reimbursed in full from the unemployment insurance budget, compared to 50% as it settled for the remaining employees. Also, employers receive a monthly amount of about 115 EUR for each disabled person employed irrespective of the type or degree of disability (employers with more than 50 employees receive this subsidy for people with disabilities employed more than 4% mandatory quota of staff). In case of hiring young graduates with disabilities, the employer generally may receive subsidy for young graduates for a longer period (18 months versus 12 months as it is for those without disabilities).

A person with a disability certificate may cumulate, regardless of the degree of disability, income from salaries monthly allowance (care costs) and additional personal budget. Disability pension is granted

if at least 50% loss of working capacity in relation to the requirements of the position held previously. For grades I and II are deemed to have lost all capacity for work, and third degree is granted for the loss of at least 50% of working capacity. Under these conditions only those with a III grade can work without losing pension rights. If before 1990 there were disability specific jobs (e.g., the bookbinders, the packaged products, massage - for the blind - to the achievement of wire brushes etc.), currently these activities are more diverse (e.g., screen printing, web design, tourism, computer, graphics, etc.).

For example, people with locomotors disabilities are suitable for different jobs that involve working in front of a table / desk / work bench, with no movement in other locations. Examples: operators in call centers, telephone operators, telephone operators by sales, help-desk operators, information, public relations, computer operators and other jobs working on the computer: computer operator accounts.

In a publisher people with disabilities can type the manuscript text on computer, corrections, typing on the computer. Many modern magazines on the market come bundled with various promotional items. The packaging activity of these gifts with magazines can be done by persons with disabilities. There are also posts that can easily accommodate people with different skills deficiencies: receptionist goods / services, commission xerox operator, accountant, secretary, treasurer / seller, physiotherapy, massage. In the arts and in particular plastics, people with disabilities may be used in manual finishing operations or to decorate objects made of ceramic, glass, metal, wood, leather, etc., making cards, trinkets, jewelry, small gifts, candles, handicrafts, especially unique or small series objects. People with low vision can work on the third shift (night) without consuming power for lighting. A blind person receiving the necessary assistive technology - a screen reader to translate the audio information on the desktop - can handle any job that involves working at the computer. People with hearing disabilities can face very noisy environments, which causes great stress on a person without disabilities. Otherwise, these people can cope well in all areas of activity: mechanical, light

industry (clothing), wood. People with intellectual disabilities, with careful preparation and a preliminary assessment can successfully perform job tasks that require a long routine, simple repetitive work on the treadmill. Depending on the deficiency of each person can identify the "man in the right place".

4. Conclusions

If in the developed countries people with disabilities are visible to the naked eye, in Romania, many of them prefer to remain isolated or to reduce their interaction with the outside world. Explanatory factors of this situation may be on one hand, coupled with fear of the reaction of others, and on the other hand, the poor accessibility of the social environment.

Legislation drafted in 1999 (GEO 102/1999) provided time to achieve accessibility, but these terms were not met, so that the new law in 2006, abandoned setting time limits. Despite NADP's efforts to monitor public institutions and penalize them the situation is far from being encouraging. Thus, from the institutions evaluated in 2006 and 2007 over 150 were accessible. The media has presented numerous situations in which accessibility was a formal (eg. too high angle ramps).

Romania also faces a number of problems related to poor education that preferred to hide the disabled, and to treat them as if they were unable to fend for themselves. People with disabilities are egocentric. All their lives have been grown in a climate in which the family gave them all the attention and have been assisted. Or when they engage must behave like everyone else and be treated the same. "If you want to be considered like everyone you have to behave like everyone else. Not going to call to say that you do not feel well, that you won't come today because the owner wants to have a profitable business" (Stephane Meuret).

The law 448 stipulates the establishment of Protected Units Authorized, many of them having so-called employees with disabilities just to benefit from tax relief. Such a unit should have 30% of employees with disabilities, and can receive orders and contracts without competition from the state or third parties who may choose to purchase

such products from a UPA with the money that they would give to the state for the unemployed persons with disabilities.

Because these revenues fall in the general budget it is not clear whether this money come back to people with disabilities in the form of labor market integration services, as happens in most countries that have a quota system. Given that the proliferation of special funds within the budget is not a good practice, being discouraged by the external partners that gave assistance to Romania, you can assume as a public policy the allocation of similar amounts to those collected for the employment policies, even without a separate fund.

Rationality, Intuition and Flair in Entrepreneur's Configuration - an Epistemological Approach

romulusv@seap.usv.ro

Abstract

The present paper proposes an overview of the evolution of the concept of entrepreneur in an epistemological approach. After a brief history of the concept, there are some basic economic and managerial guidelines in entrepreneur's configuration; these guidelines are found in the work of experts in management, respectively, leading economists. Rationality, flair and intuition of the entrepreneur are then analyzed in terms of existing trends in the economy, acknowledging the entrepreneurship and again stressing the importance that the entrepreneur has in a global market.

Key words: entrepreneur, entrepreneurship, limited rationality, economic rationality, limited irrationality.

J.E.L. classification: B10, L26, N8, O12

1. Introduction– the concept of entrepreneur from a historical perspective

Over time, the concept of "entrepreneur" has different meanings. A chronological approach to the concept, at least in its early stages, may be appropriate since it is difficult, or at least questionable, to set a time from which we can speak about the modern entrepreneur significantly different from the traditional one. The evolution of society as a whole up to current stage - the stage of knowledge society - or individualization of new sciences derived from economics may constitute as many landmarks in entrepreneur's configuration.

In the *early years*, the typical entrepreneur could be found among the military and merchants. At that time, wars were often deployed for economic reasons; the military leaders, assuming considerable risks, could achieve substantial gains through a successful strategy. The merchants of those times were risking their fortunes too. The merchant and adventurer could often be found in the same person. Marco Polo, for example, was an adventurer who sought to establish trade routes to the Far East. The adventurer-merchant was assuming physical and emotional risk of such an action, and the capitalist, the economic risk. At the end of the mission, the capitalist received 75% of earnings and merchant the rest.

Because the trade in the *Middle Ages* was considered a degrading act because of the existence of church restrictions on the supply of capital, the entrepreneur typically was a cleric. He had as assignment the construction of large architectural works, such as castles and fortifications, public buildings, monasteries and cathedrals. Employed in such huge projects, the entrepreneur does not assume any risk, but rather was a project leader who used the resources most of the times provided by the government. Although primarily concerned with ethics, medieval writers, however, said that a good trader must be steady in taking risks and well-informed about quality, price and cost of goods, pay attention to detail and emotionally prepared in case of failure.

The entrepreneur of the *seventeenth century* was the person who enters into a contractual arrangement with the government to provide a service or purchase a product, assuming the risk of such transactions. Since the contract price was fixed, the entrepreneur can win or lose in the transaction, as he

bought at a lower or higher price. In England, land speculators and farmers were considered entrepreneurs.

The eighteenth century brought the first explanations of the concept of entrepreneurship as we perceive today. The first use of the term *entrepreneur* in an economic context is attributed to Richard Cantillon in his work „Essai sur la nature de commerce en general”[1], published in 1755, 21 years after his death. Cantillon gives a broad definition of entrepreneur. According to his definition, the entrepreneur is the agent who purchases inputs to combine them into products for sale on the market, while the costs are known and certain, and the income is unknown and uncertain. The uncertainty of income lies in the fact that the market demand can not be fully known. He considers the entrepreneur the main figure in economy.

In the same period, in England takes place the industrial revolution, a process in which the entrepreneur had a visible role in taking risks and transforming resources. The term „adventure” associated to the entrepreneur left gradually the place for „undertaker”, about which Adam Smith wrote that has become synonymous with regular businessman [2].

Also during this period the entrepreneur was particularly different from the capitalist. Many inventions of the industrial revolution would not have been possible without the support of the capital owners who did not have an entrepreneurial spirit. Thomas Edison, for example, to carry out his experiments in chemistry and electricity resorted to various private sources of capital.

2. Reference points in economics and management regarding to entrepreneur's configuration

2.1. Jean Baptiste Say

Jean Baptiste Say is a famous scientist, considered the first professor in the field of political economy in Europe. He brings an important contribution in developing the concept of entrepreneurship. Moreover, Jean Baptiste Say was also entrepreneur, which allowed him a better understanding of the entrepreneur's business activity. Say's definition of entrepreneur puts him in a more

specialized and detailed role, being less general. He believes that the entrepreneur must have „... judgment, perseverance and an understanding of world and business. He must estimate the importance of product with tolerable accuracy, the probable demand and the factors of production required at a given time, on the other hand, he has to buy raw materials, to ensure the workforce, to identify customers, paying particular attention to the economy and policy, in a word, he must possess the art of control and administration.” Say insists on the need for simultaneous affirmation of these qualities as a condition for success in business. If any of the above qualities is missing, then the activity of the entrepreneur might fail. [3]

The crucial role of the entrepreneur in the allocation and reallocation of resources where there is a perpetual imbalance (due to the fact that supply and demand are in a permanent change) was noted since 1871 by the Austrian school's founder, Carl Menger. He stressed the entrepreneur's need for information and his ability to analyze it successfully in order to be able to allocate properly resources. Menger has also examined the role of uncertainty to entrepreneur's activity. [4]

British classic economists have given to entrepreneur a minor role in overall economic activity, considering that he only provides capital, and does not play a direct role in leading this process. English Classical School addressed the economic issues mainly at the macroeconomic level. If British classical liberals gave a less importance to the entrepreneur, considering that he is only meant to provide the business with necessary capital and having an indirect role in guiding this process, during the subsequent period the economic reality proved the groundlessness of this attitude.

2.2. Joseph Schumpeter

Thus, in the *twentieth century*, the entrepreneur has become synonymous or at least associated with free enterprise and capitalism. He is recognized as an agent of change. The entrepreneur is a creative person with innovative business ideas that contribute to business growth and profitability.

A major contribution to deepening the concept of entrepreneurship and its role was made by Joseph Schumpeter (1954). The key word in his work relating to entrepreneur is innovation; the two concepts practically overlap in his work. He believes that the entrepreneur is the person who makes a new product or new production process, a new combination of the factors of production, in essence, through an innovation.

In Schumpeter's view, the true entrepreneur is no longer seen as a person who responds to market forces or to an adjustment process led by a new relation between supply and demand, but rather as the person that causes the change. [5]

Joseph Schumpeter disagrees to marshallian definition of the entrepreneur - according to which the entrepreneur function is an "administration" function taken in its broadest meaning - saying that it is currently performed by individuals with a high degree of talent and professionalism. The rarity of the successful entrepreneurs lies in their psychology.[6] Although they are rational economic people, their aim is not simply following consumption, in a common sense.

At the beginning of last century, Schumpeter's theory on entrepreneur's "innovative spirit", who carries out new combinations of existing things, becoming a promoter of innovation progress and generator of economic progress, enjoyed high ratings, especially since it explained the economic superiority of capitalism against the socialist alternative.[7] This is because individual liberties, freedom of social relations, civil rights - as basic pillars of democracy, which yet can operate only in capitalism - have been translated into free trade and labor in economic terms. These basic trends are also reflected by the liberal philosophy of Scotsman David Hume (1711-1776), which revealed that the competitive system fosters the spirit of competition among countries and among ordinary individuals. [8]

2.3. Herbert Simon

The neoclassical theory states as main objective for entrepreneur the profit maximization. If this is the owner of the company and perform turnovers higher than

explicit and implicit costs then he obtain a higher income than that he would obtain from the best alternative use of its resources. To achieve this objective, the company adopts an optimization behavior based on complete rationality and obtains, in this way, a maximum profit [9]. The neoclassical model is missing, however, the central character: the entrepreneur, respectively he is treated impersonally as long as the neoclassical company is presented as an agent without dimensions ("point company") and as a passive agent ("automatic company").

One of the most famous economists who have criticized the classical model of rationality is Herbert Simon who proposed the concept of *procedural* or *limited rationality* which constitutes a major contribution to the decision theory within economic organizations, and for which he received the Nobel Prize for Economics 1978. The perfect rationality from the classical model - which is based on decision results, and objectives and means of achieving them are considered a priori - is replaced with procedural or limited rationality - which is based on decision-making procedures, and objectives and means of achieving them is taken as a baseline and as a result of the research. [10]

Whereas the twentieth century marks the emergence and development of management as an independent science, the concerns aimed at entrepreneur's configuration receive a special focus given primarily by changing the macroeconomic analysis framework to the microeconomic level of analysis.

As regards the rationality, it is most often encountered in addressing decision-making processes within firms. Therefore, in essence, Simon argues that the rationality of decisions in organizations is affected (limited) by two major factors: the limited cognitive capacities of decision makers and the constraints of the organizational environment. As a result of the influence of these factors, managers often renounce to "inventorize" all possible alternatives to find the best, and they are contented to examine a limited number of alternatives, retaining the first one that they seem to be satisfactory (good enough). [11]

But what fundamentally distinguishes entrepreneur from other players in the business and social environment is action, for

which his configuration analysis emphasis on its behavior determined by *economic rationality*, namely the choice of the best ways to use resources to maximize the objective on the one hand, and on the other hand, to ensure coherent functioning to economic structures of the enterprise and / or of a national level. [12] In this sense, the *intuition* of the entrepreneur can occur in: investigation of internal and external environment through inspired seeking and interpretation of relevant information; identifying the real problem by detecting some causal link less obvious by logical way; generating new and unusual alternatives; evaluating the generated solutions by estimating the evolution of some uncontrollable factors (intuitive prediction); selecting a solution; implementing the decision by choosing inspired ways to achieve the planned actions.

2.4. Peter Drucker

The famous American professor Peter Drucker, considered a guru of modern management, defines the entrepreneur in a pragmatic manner, from a managerial perspective. He believes that the entrepreneur is always looking for change, identify it, respond to it and exploit it as an opportunity, and its activity is neither science nor art, but practice. Drucker's definition focuses on the existence of a genuine culture of entrepreneurship, which is based on exploiting new market opportunities. The author believes that the characteristic features of entrepreneur's successful behavior can be developed within existing organizations, so ensuring a competitive advantage. (This definition is in line with American pragmatic school, being found also to other authors). In same context, Sexton, Kent and Vesper (1982) believes that entrepreneur is not any business owner-manager. If an innovative aspect of its activity does not appear, it can be considered an administrator.[13] As a result, says Drucker, the entrepreneur must be seen from the perspective of results which he achieve in business and less in terms of what he is as a distinct personality. [14]

Currently, in developed countries, the entrepreneurs' behavior becomes more strategic, seeking to change the external

environment conditions, whereas they activates mostly in foreign markets with increased competition. Therefore, open market competition plays the role of entrepreneurs' coordination and the connection of production to consumption. This coordination is achieved through profit and loss mechanism which, on the one hand, rewards the entrepreneurs who anticipate correctly the public desires and allocates resources towards meeting these needs and, on the other hand, amends the entrepreneurs who waste resources by investing them in less important directions. The continuous entrepreneurial class selection made by the competition ensures the coordination of individuals plans (as F. Hayek said) or harmony of interests (as F. Bastiat said) [15] by the phenomenon of "creative destruction" mentioned by Schumpeter [16].

Therefore, in the contemporary economy, "the entrepreneur's ability" is considered a special human resource, a neo-factor of production required to combine the other factors of production in terms of efficiency, to manifest the motion and the degree of adaptability to market requirements, to produce new economic goods, to find the most advantageous supply sources and markets, to assume the risks of making and implementing economic decisions. Therefore, the entrepreneur has his role well defined. He manifests itself as a true "interface" of production and consumption processes, called to ensure the achievement and maintenance of company's competitive advantage in the global market. [17]

3. Current trends in addressing the concept of entrepreneur

Thus, the entrepreneur's configuration can be analyzed in relation to company's development as an independent entity: if we consider its various operating forms (legal status) or its size, from small and very small businesses to transnational corporations, we can talk about the emergence of *collective entrepreneur*, about process of group decision making, about innovation through cooperation etc. Although many of the assertions presented in this paper also refer to collectively entrepreneur, the generic name is the same: entrepreneur. Management

literature explores separately the two concepts and delimits them the roles and functions (for example, many books, articles and studies are dedicated to small and medium enterprises, in which the central figure is the individual entrepreneur).

Increasingly present in management literature, but also in practice, is the notion of *entrepreneurship* defined as the process by which an individual or a group of individuals called employers or entrepreneurs, make organized efforts to exploit the existing market opportunities, explicitly appealing to innovation and adaptation to change. [18]

According to Drucker, the management was the new technology that has transformed the American economy into an entrepreneurial economy; it is concerning successive innovations in education, healthcare, government, business, economy and society. [19]

Entrepreneurship means monitoring the environment trends and changes in the market or in society which nobody has seen or has not paid attention to before. [20] The most important aspect regarding to entrepreneurship is related to innovation and adaptation to changing required by market and / or society; it involves change, the introduction of new products / services or of new ways of doing business. [21]

In general, having as reference the management literature, in recent years is made little distinction, at least for small and medium sized companies, between the entrepreneur-owner and manager-owner. Unlike classical design, the owner of capital is not seen as an entrepreneur as long as he is not the one who is running the business. And this is not because things wouldn't stay that way (he make the initial decision to invest his money in a business, "undertake" this first step), but the emphasis is placed on the diversity of roles and activities which must be fulfilled, respectively, performed, by the managers who run that business.

Thus, in most management works can be found various typologies of entrepreneurs, each identified type comprising a range of personality characteristics, abilities and skills, more or less similar, more or less specific. Among these typologies is found also the criterion of ownership that marks the difference mentioned above, but only this: for example, there are not analyzed in depth

the relations between owners and those who manage their businesses, respectively the extent to which the latter ones are free to operate in accordance with the training they have and with their understanding of those businesses. In other words, how much power of decision they have and if this is limited, to what extent they have the responsibility of implementing the decisions, with the whole "suite" of consequences arising therefrom.

Given those written before, we believe that intuition is implicit in the entrepreneur's conception of innovation - inherently linked to the concept of entrepreneur - and flair, defined as "sense of quickly orientation in a difficult circumstance or situation" (DEX) is inextricably linked with the intuition materialization by putting the innovation into practice (in the schumpeterian sense and not only) at the right time and right place. Moreover, flair is the expression of the strategic dimension of entrepreneur's thinking, and without it he can not cope with the frequent and rapid changes specific to the current economy. As an example, we can examine how the manager-owner (as generally, the entrepreneur) faces the growing crisis of the company that he started it: the moment of enthusiastic beginning (the intuition of profitable business idea and its implementation) will be overshadowed by the problems posed by the need to extend organizational structure and to delegate attributions. Initially, flair will be useful for him, especially since the changes will be rapid, after which the he will feel the need, among others, to use the well-known strategic management tools as rational option for company's management.

On the other hand, as an extension of Simon 's thinking about limited rationality of individuals (in this case, the entrepreneur) in addressing the organizations decision-making processes was introduced the term of *limited irrationality* (LI) which can be defined as a specific human behavior whose basic principle to human activity system is represented by the logical-rational structures, but which as an exception (in limited circumstances), also calls the experience, intuition and imagination; in other words, LI is a sequence of "extra-logical" accepted as an exception from the desire to highlight the three components invoked, respectively experience, intuition and imagination. [22]

This is because human thinking (therefore entrepreneur's thinking) is far from being perfect and precise, both rational and irrational are being specifically human attributes; the idea that the irrational may put its mark in a positive sense, on an individual's rational approach is not new, being frequently found in many scientific papers. For example, Karl Popper believes that scientific discovery is, in essence, an irrational moment to which you can not attain to any logical path as it is based solely on purest intuition. [23]

We could say that a modern approach to the concept of entrepreneur has to take into account issues that have totally changed the current business environment, primarily related aspects of the information revolution. The abundance of information available due to Internet proliferation can not contradict the theory of limited rationality of H. Simon, maybe even strengthened it because of redundancy phenomena that occur many times and, paradoxically, impede the communication.

However, mutations occurring in the contemporary economy show transition increasingly obvious to another form of economy - the knowledge economy - where businesses based on knowledge have an important place. They are becoming more numerous and extend throughout many areas, generating the need for a new type of entrepreneurs: providers of knowledge entrepreneurs, entrepreneurs in the field of information and services on the web. The knowledge economy is creating new business opportunities and, of course, entrepreneurs to fill this niche market. [24]

The entrepreneurship and capital accumulation as endogenous features of an economic system, give the measure of current and potential progress in society. Not every manager, whether he is worthy, is also a visionary, capable to identify major opportunities. Joseph Schumpeter, with his famous "Theory of Economic Development" and the Austrian (neo-Austrian) school generally have significantly contributed to explaining the role of entrepreneur in economic growth. History of recent decades shows exemplary entrepreneurs; it is enough to think of a Bill Gates, who formed what has become the Microsoft, or the team that has made Nokia a world leader in

telecommunications equipment. Likewise intense capital accumulation, as investment process, ensures sustainable economic growth. New information and communication technologies emphasizes the role of entrepreneurship, knowledge (based on higher education), for economic growth. [25]

4. Conclusions

A fundamental role in entrepreneur's configuration we believe that have the institutional framework in which he acts, and not only the markets which he addresses to. Entrepreneur's behavior will be the more opportunistic the more he will be forced to act in situations of economic instability or unfavorable circumstances in a legal framework with serious gaps. Moreover, he will use his rationality, flair and intuition not to create value, but to exploit the weaknesses of social-economic system in which he operates. If he finds itself constrained to do so or not remain an open question. It is certain that over a long period of time, this behavior tends to become a tradition, and a model to follow due to the lack of alternative.

Thus, "the behavioral patterns that have passed «the customs» (n. are selected by market) are those consonant with the environmental rules. The sum of these rules is a condensed experience, consumed in the spirit of rationality. Also from rationalist spirit (but without making a special concern of this) economic agents assume this experience and imitate it. Rather than rewrite the history of business, is more comfortable ("rational") to take it over and eventually transmit it further." [26]

We believe that opinions presented in this paper are far from circumscribing a frame of reference for configuring the entrepreneur from yesterday and nowadays especially since the perspectives of analysis are somehow different: on the one hand, pure economy on the other hand, sciences derived from it. As each has developed its own concepts and analysis tools balancing the points of view in a language understandable for all specialists in economics of one kind or another, becomes a laborious approach.

Personally we are much closer to the managerial approach but we consider extremely useful the widening of entrepreneur's analysis framework beyond the company's boundaries whereas the microeconomic perspective often personalizes up to superficiality and the macroeconomic depersonalizes up to excessive formalism.

The Synergy Issues in Organizations' Strategies in a Global Economy

Zoltan Raluca

"Ștefan cel Mare" University of Suceava
ralucaz@seap.usv.ro

Abstract

The present paper aims to define the concept of synergy in the context of strategic management of organizations and to emphasize the importance of taking it into consideration by the companies that activate today in a global economy. The transposition of synergy into objectives aimed by the company depends on whether the strategy would be implemented according to the available resources and these objectives may take the form of operating synergy, investment synergy, managerial synergy etc.

Thus, there are presented considerations concerning the strategic analysis and strategic segmentation tools through which companies will identify which strategy are timely and, especially, which ones will lead to achieving the expected synergy effects. It is also argued the special attention that should be paid to implementation of corporate-level strategies and to the role of human resources in achieving synergy effects.

Key words: synergy, synergy effects, strategic segmentation tools, organization level strategies, corporate-level strategies

J.E.L. classification: L1, L2, M1, O3

1. Introduction

According to the company's systemic approach, the concept of synergy is quite limited to the meaning of "to link", "to work together" in order to achieve the aim of the company seen as a whole. In a wider understanding of the term, synergy means to achieve in joint action of the elements that make the system a better result than the sum of individual actions, respectively $1 + 1 = 2$ or $2 + 2 = 5$. These non-mathematical relations reveal the existence of the subsystems interdependence, they couldn't operate one without another under the

conditions of pre-existing common objectives.

Haken (1984), the founder of Synergetics, points that the synergy refers mainly to transactions related to several subsystems (generally, the same or different) to generate an ordered structure and a system functions at a macroscopic level. (Qingrui Xu and others, 2007) Since the business organizations are complex systems, the attempt to define and measure the synergy effects arising from activities taking place within them (and between them) is a difficult endeavor that requires different approaches depending on the specific area covered. Therefore the synergy issue in implementing the strategies firms was not a major and self-reliant theme for researchers and practitioners than in a small extent or tangential.

2. The synergy in Ansoff's strategic model

Over the years, a significant amount of research on strategic management has been devoted to identifying what companies should do to increase their business value and gain competitive advantage. The *synergy effect* term was first introduced by Igor Ansoff in the '60s as a generic definition for effects derived from the union between two products or markets. The basic idea was that the combination effects may lead to an increased value that was impossible to obtain separately. (Ansoff, 1965 apud Nedelcu, 2008)

Igor Ansoff described the synergy as the combined effects of two products or markets. Synergy, he says, occurs when the two combined resources generate results greater than the amount of each part. He discusses on 4 types of synergy: sales synergy, operational synergy, management synergy and investments synergy. Ansoff argued that the most successful companies are those that manage to exploit advantages in core

business through diversification on carefully selected markets. This diversification may then lead to positive effects of synergy. (Ansoff, 1965 apud Goldberg and Katz, 2008) Furthermore, synergy in the use of organizational resources in Ansoff's view encompasses an inherent part of any strategy. Similarly, R. Daft considers synergy a component of the strategy and it "defines the conditions that exist when components of the organization interact, producing a greater effect than that obtained by the action of separate parts." (Istocescu, 2005)

The realization of potential synergies may occur on different organizational levels, by reducing costs and increasing revenues. However, with a poor implementation of the strategy, synergies will be limited or even negative. (Ansoff, 1965 apud Goldberg and Katz, 2008). Therefore is essential to design a strategic plan, which sets overall strategy of the organization (broken in several types of strategies, such as administrative, financial and based on the product-market) expressed in the form of objectives whose multiple origin is to be frequently revised. (Istocescu, 2005)

Prospects so far have been those that synergies are created between businesses, which explains the use of nothing else but external data. However, according to Ansoff, the synergy creating is actually likely to occur at different levels of organization which may mean, for example, that synergies are created between business units or specific activities rather than from current businesses. "Corporate strategy must move beyond the idea that the main way to create synergy is combining related businesses. In this case, external data may well be an insufficient source for analysis, while internal data may provide a further understanding of the process of diversification." (Goldberg and Katz, 2008)

Thus, the synergy approach in the strategic options of the company requires, at least in theory, a separation of organizational levels at which value-added can be obtained and, especially, the identification of strategic instruments able to guide the most effective strategic decisions in this regard.

3. The strategic environmental analysis – framework for identifying potential synergy

The general environmental analysis (using PEST model, SWOT analysis, McKinsey 7S model or PIMS) in which the organization operates is the first step in its efforts to achieve synergy in applying one or more management strategies.

The PEST analysis is a useful tool for understanding market growth or decline. PEST is an acronym for Political, Economic, Social and Technological factors, which are used to assess the market for a business or organizational unit. The PEST analysis headings are a framework for reviewing a situation, and can also, be used to review a strategy or position, direction of a company, a marketing proposition, or idea.

The SWOT analysis is an extremely useful tool for understanding and decision-making for all sorts of situations in business and organizations. SWOT is an acronym for Strengths, Weaknesses, Opportunities, and Threats and provides a good framework for reviewing strategy, position and direction of a company or business. The strengths and weaknesses refer to the internal environment, while the opportunities and threats concern the external environment.

The McKinsey 7S model involves seven interdependent factors which are:

- *Strategy*: the plan devised to maintain and build competitive advantage over the competition.
- *Structure*: the way the organization is structured and who reports to whom.
- *Systems*: the daily activities and procedures that staff members engage in to get the job done.
- *Shared Values*: called "superordinate goals"; when the model was first developed, these were the core values of the company that are evidenced in the corporate culture and the general work ethic.
- *Style*: the style of leadership adopted.
- *Staff*: the employees and their general capabilities.
- *Skills*: the actual skills and competencies of the employees working for the company.

Whatever the type of change - restructuring, new processes, organizational merger, new systems, change of leadership,

and so on - the model can be used to understand how the organizational elements are interrelated, and so ensure that the wider impact of changes made in one area is taken into consideration.

Profit Impact of Market strategy (PIMS) is a database of the market profiles and business results of major American and European companies. It was developed with the intention of providing empirical evidence of which business strategies lead to success, within particular industries. Some of the most important strategic variables studied were market share, product quality, investment intensity, and service quality (all of which were found to be highly correlated with profitability).

Porter's Five Forces model can be used to good analytical effect alongside other models such as the SWOT and PEST analysis. The five forces that Porter suggests drive competition are: existing competitive rivalry between suppliers, threat of new market entrants, bargaining power of buyers, power of suppliers, threat of substitute products (including technology change).

The analysis of competitive environment (using Porter's five forces model) and the value chain analysis (Porter, 2001) may be followed by an analysis of external value chain, respectively Suppliers-Enterprise-Distributors-Customer, whereas the basis of "benchmarking" concept is the comparison of value chains of competitors. (Țuclea, 2003) This is important because benchmarking is a continuous process of assessment relative to the best. Its results are process practices and objectives that can be evaluated on the basis of what is the best in the business or is expected to begin and is the rational way to meet customer requirements and to pursue this process, in parallel with customers' needs change over time (Băcanu, 2007)

4. The usefulness of strategic segmentation tools in achieving synergy

The first concerns in strategic management popularized several strategic segmentation and management of businesses portfolio tools useful when they appear, but

less usable in the current competitive context, such as:

- BCG matrix – based on the field lifecycle, inspired by the product lifecycle and the experience curve,
- ADL matrix – based on activity maturity and competitive position in business,
- McKinsey matrix – built on the same variables as the previous, activity growth and competitive position of the company etc.

The evaluation of McKinsey matrix is based on the ADL model by introducing a greater number of KFS (key factors of success). Regarding to attractiveness of the sector, it is finer measured based on criteria reflecting the business own interest: the existence of synergies with other business activities, the possibility or impossibility of raising entry barriers, the security of supply and distribution. (Carpentier and others, 2002) But "these methods are considered too mechanical, even simplistic (BCG) or empirical (ADL and McKinsey) (...) the set policy guidelines are not accompanied by any assessment of the implementing means ". (Carpentier and others, 2002)

However, concerning the portfolio matrices, the current trend of portfolio techniques is to shift the emphasis on industry attractiveness and business position on how the businesses of a portfolio fit together (Johnson, Scholes and Whittington, 2005 apud Băcanu, 2006). It is considered that these must be evaluated also in terms of synergies that arise between them and shared skills. On the other hand, the question arises whether the competencies must be concentrated by parent company, so that it can generate a maximized combination of synergies within existing businesses.

This has implications for the classical set of recommendations relative to the positions in the matrix: partial liquidation is now recommended for business that doesn't match the rest of the portfolio, and not the business that presents poor performances in an unattractive industry. This kind of recommendation correlates with that which suggests to keep businesses that are understood by the company and to take into account the matching between competencies and the chosen business rather than performances of the business judged as independent. (Băcanu, 2006)

5. The synergy effects on corporate-level strategies

Within organization internal environment the synergy is absolutely necessary for its operation as a system. As for the company's external relations through partnerships and strategic alliances or creating new entities through mergers and acquisitions, the synergy is the only reason for cooperation and collaboration. The correct identification of complementarities and interdependencies between activities, groups / teams, structures etc. is a prerequisite for obtaining both desired synergy effects and especially for avoiding negative synergy since "synergy can also be negative, not only positive, such as mathematical representations $1 + 1 = 3$ or $2 + 2 = 5$ suggested". (Popescu, 2004)

Thus, the research in recent years has focused on studying the effects of synergy desirable and obtainable by appealing to corporate-level strategies such as mergers, acquisitions, strategic alliances etc. because "a few companies can create their future on their own; most of them need a helping hand". (Hamel and Prahalad, 2008)

Achieving the synergy effects through mergers and acquisitions, particularly in the implementation stage – because they, mostly, fails in this task – depends, first of all, on the opportunity for integration, the cultural compatibility and other compatibilities, the time after which it can be "seen" the synergy effects (Andersson-Thunberg, Fjellman and Partin, 2008). It also depends on the potential for combining (strategic complementarities and similarities), organizational integration, employees resistance to change and experience in the synergy achievement (the experience in acquisitions or mergers) (Andersson and Karlsson de la Rosa, 2006). Then, these effects – following Ansoff's classification – are essential in maintaining the sustainable competitive advantage in international context (Bjerde and Stahl, 2009) and the main factors that can influence the level of synergy are the resources, the partner characteristics, the relationships between partners, the partnerships characteristics and the external environment. (Lasker, RD and ES Weiss, Miller, R., 2001)

By pursuing the synergy effects in creating strategic alliances, partners can counteract the external markets risks or can outlast in a

crisis period (Pangarkar, 2007) by creating the GSA (Global Strategy Alliance) that bring together the strengths of partners and their complementary resources (Kim, J. and Parkhe, A., 2009), although they will have difficulties because a portfolio of business becoming more diverse in terms of product diversification requires the firms to cope with an increasing level of high complexity, which influences the ability to implement and execute projects for future expansion. (Hutzschenreuter and Guenther, 2009) The motivations for engaging in alliances relate to risk reduction, anticipated economies of scale, market entry, diversification of products portfolio, technological synergy, product or service innovation, collaboration of R & D departments, information exchange or risk sharing within the capital intensive companies. In all these cases, the resources or skills portfolio of companies should be complementary so as to the alliance to generate value for both partners. (Phan, P.H., 2000)

But generally "global domination by brand, sharing the distribution channels and the resources, economies of scale" (Chng and Pangarkar, 2000), available both for MNC (Multinational Company) and for various strategic partnerships, may be considered as many synergy effects as far as the major goals of any organization, namely: achieving efficiency, management of specific risks and development of internal capabilities for innovation and adaptation to future changes, are accomplished.

6. The human resources role in synergy creating

Whatever the type of organization or the type of strategy chosen, the fundamental role in creating and achieving synergy is the human factor because "people are a major source of competitive advantage". (Armstrong, 2003)

Since "not the capital, not the income and not the material resources but human resources is the ultimate foundation of wealth nations" and "human beings are active agents that accumulate the capital, exploit the natural resources, build the social organizations, and promote the economic and political development of nations" (Harbison, 1973), knowledge / skills and qualifications /

multiple qualifications held by human resources within organizations (managers and non-managers) are essential to achieve the synergy effects in analysis, implementation and evaluation of strategic alternatives.

Lifelong learning is a desideratum for all modern organizations, so necessary for survival in a highly competitive environment (through continuous improvement and training of human resources), and, especially, for the possibility of growth, differentiation and diversification by exploiting the synergy effect of teams (managerial teams and operational teams). This can be achieved insofar the inspiring managers / team leaders exist whereas "the synergy is the essence of leadership centered on principles" and it operates effectively in a reality of interdependence – it means teamwork, team building, creating a union between human beings, fostering creativity. (Corvey, 2002)

Also, the continuous learning processes involved by benchmarking is the basis of synergy effects emergence at the teams level, and they can be identified through approaches such as the *microfoundations*, which means "the study of organizations in terms of individual actions and interactions, as a solution to the challenges imposed by learning organization, knowledge transfer, innovation and competitive advantage" (Felin and Foss, 2006) or *developmental work* (DW), which promises (to the employees) a number of possibilities for both working environment improvement and involvement in strategic decisions making and issues related to corporate social responsibility". (Hvide, H. and Møller, N., 2001)

Then, because any implementation of a strategic alternative means change, and this determines mostly unwanted effects on human resources, is needed a proper management of the transition through new desired situation. Especially since the target is to achieve synergy, it is necessary to differentiate between evolutionary change, management change, sequential change and complex change (Hrebiniak, 2009) and to assess the advantages and disadvantages that each of them implies.

7. Conclusions

The low interest in a distinct approach of synergy concept in the strategic analysis and strategies implementation and evaluation comes from the difficulty of locating and measuring the effects of synergy.

Even so, synergy can be approached from a dual perspective: on the one hand, identifying it involves a quantitative analysis of results obtained from the formation of new system (especially for acquisitions, mergers or other strategic alternatives that induce major structural and operational changes); on the other hand, a qualitative analysis of intangible resources that significantly affect the overall results of the organization (know-how, skills, knowledge, relationships, agreements etc.).

If in the first case, the synergy effects can be measured in terms of efficiency, profitability, cost reduction etc. by calculating the economic indicators in each entity and comparing the value of the same indicators in the new system formed (*Any incremental change inherent in the application of any strategy will lead to changes in the original system (the organization as a whole or any subsystem of it)*).

In the second case, as regard to the synergy of teams, synergic communication, agreements development etc. it is required the identification and assessment of qualitative factors likely to influence overall results. In both cases, the time factor is of paramount importance because the synergy implies not only the valorization of interdependences and differences but also synchronization and compatibility.

We can conclude that in the strategies development and materialization the emphasis must be placed equally on operationalization of know-how concept and also of the know-why concept (the detailed examination of compatibilities, interdependences and synchronizations) and of the know-who concept (the in depth analysis of human resources implicated and / or affected by the change process induced by the strategy implementation), their convergence in organizations ensuring the premises for obtaining synergy effects in implementation of strategies.
