Informal Employment in Romania in the Actual European Context

Aceleanu Mirela Ionela
Academy of Economic Studies, Bucharest
aceleanu_mirela@yahoo.com

Abstract

The labour market in Romania is faced with many problems such as certain demographic imbalances, legislative instability, a weak correlation between educational supplies with market demands and a rising of informal economy and informal employment.

The paper aims to capture the labour market conditions in Romania in terms of informal employment in the current context. Informal employment in Romania cannot be understood without recognizing its diverse nature. There are presented some causes and forms of the informal employment in Romania in order to identify measures to reduce it.

Key words: labour market, informal employment, undeclared work

J.E.L classification: E 26, J 0

1. Features of labour market

The labour market has formed and operates in conjunction with the role of the labour in economic and social development and general requirements in markets and price theory.

The labour market represents all acts of sale and purchase of labour, of the relations with their specific, taking place in an economic space.

Man is more than merchandise, so that the labour market has a special place in economic theory and practice, as a secondary market and regulated. It is heterogeneous, encompassing several areas of activities defined by gender, the economic zones, the professions or occupations, the categories and skill levels, etc.

As a secondary market, it receives the influences the other markets and also generates effects that are found in all socio-

economic sectors. The labour market behaves, on the one hand, as any market and, on the other hand, has its own characteristics, determined by the human specific of the object with which it operates and that of services generated by it.

The historical experience shows us that the labour market always involves establishing relationships between carriers and demand of labour supply. This determines certain specifics regarding the adjustment of supply and demand, on price formation of the labour, the existence of a system of norms and social values.

The labour market represents one of the most complex forms of market existing in the economy, because the factor that is traded is labour. This factor is composed of a series of bio-psychological, demographic, educational and behavioral characteristics, which clearly distinguishes it from any other factor that falls under the exchange relations in other markets.

All the time and space conditions, the economic activity involves the labour factor systematically designed to value the resources to his interest. Like other factors of production, they are obtained through the market that is a *subsystem of the economy of a competitive market*. Transactions in this market have as their object work or labour force.

If we understand labour force as a total of the physical and intellectual skills that exist in the human life and personality and that he puts into service when they create economic goods, then work represents conscious labour- spending.

In specialized literature, it is considered that in the *process of development and operation of the national economy, employment fulfills important economic, socio-economic and educational functions*. It ensures the implementation of balance between the needs of work resources of the national economy and their employment

opportunities; determines the orientation of use of labour resources of each country, both by assigning them to jobs, branches and cities, and by their use in each market economic units; and makes the process of unification and combination of the human factor with the material ones of production, it influences the shaping and the revenue sharing.

The labour market has an active role within the market system. In support this role it is considered the first fact, that the market is the most important factor of production. Work is the production factor which contributes decisively to the creation, development and improvement of other production factors.

The labour market in Romania is faced with certain demographic imbalances, with legislative instability and weak correlation between educational supplies with market demands. In recent years, the economic and financial crisis led to increased the informal economy.

2. Informal employment –conceptual approach

The informal economy is present in all societies irrespective of their dominant social and political system. Nevertheless, there are considerable differences in the scope and form that the informal economy may assume in each society. In developing countries, the informal economy is linked neither to fringe groups, nor to additional job opportunities; nor is it a response to the rigidity of the government's plan. It is rather the consequence of the dual economic structure and itself the result of economic underdevelopment.

Pisces Pierre's definition, according to which the shadow economy is "all the economic activity occurred outside the criminal, social or fiscal laws or the ones that escape the national inventory", is considered by specialists as being the most comprehensive definition of the informal economy (Radulescu, 2007). Informal employment is the most important part of the underground economy.

Informal employment is defined as the '*total number of informal jobs, whether carried out in formal sector enterprises, informal sector enterprises, or households*'

(ILO, 2002).

There has been a revival of research on informal employment and labour market segmentation in developing countries over the last two decades. There are 3 point of view about the nature of informal employment, taking recourse to three schools of thought. (Lehmann, Pignatti, 2007)

The traditional school (classical) sees informal employment as a predominantly involuntary engagement of workers in a segmented labour market: there is a primary, formal labour market with "good" jobs, i.e. well paid jobs with substantial fringe benefits, and a secondary, informal labour market with "bad" jobs, i.e. having the opposite characteristics of the good jobs. All workers would like to work in the primary labour market, but access to it is restricted, while there is free entry to the secondary labour market.

The second school of thought by the contributions of Rosenzweig (1988) and Maloney (2004) shows that many workers choose informal employment voluntarily. This school of thought also raises doubts about the preferability of formal sector jobs along the various dimensions mentioned in the traditional literature on labour market segmentation. For example, if formal employment is linked with the provision of pension benefits, in less developed countries such benefits might not be unequivocally good in the eyes of the employed. Health care benefits provide a second example for the possibly dubious nature of fringe benefits connected to formal employment. Having health care insurance might be undesirable because of the low quality of health services or unnecessary because of family coverage of the health insurance through another member of the household. Also, given that this benefits generate costs to the employer – who might or might not be able to shift these costs on to the worker – it is not a priori clear that wages are lower in the informal sector, and empirical evidence is required to establish the relative wage levels.

The third strand in the literature starts out with the labour market segmented into a formal and informal sector. It paints, however, a more complex picture of labour market segmentation than the traditional school of thought as it sees "upper tier jobs" and "free entry jobs" in the secondary,

informal sector. Access to "upper tier jobs" – good jobs that people like to take up in the informal sector – is restricted. Most of the jobs in the secondary, informal sector are "free entry jobs", which can be had by anyone and which people only involuntarily take up.

Of course, the reality of labour markets in developing countries is complex and the available evidence does not lead to the acceptance of one school of thought and the unequivocal rejection of the other competing paradigms. The evidence suggests, instead, that labour markets in developing countries exhibit characteristics that point to the partial validity of all three schools of thought.

3. Informal economy and informal employment in Romania

The extent of the underground economy and informal employment in Romania has taken alarming proportions, which can threaten the macroeconomic and macro social balance. A high scale of the underground economy has as the main negative effects the decrease of the growth rate for the official economy.

Informal employment is one of the key features of the Romanian labour market. Most people have been going into the informal economy because they cannot find jobs or are unable to start businesses in the formal economy.

Sectors where it is practiced informal work are about the same in all EU countries, such as the fields of construction, repair of cars, clothing, tailoring, agriculture, tourism, barber shops, street vendors or at home, housekeeping, childcare, legal advice, tax or accounting. Despite the apparent heterogeneity, these industries have some common points: they require little infrastructure and can be made more often at home or in small units.

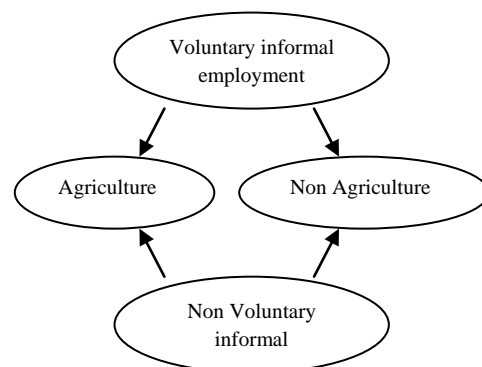

Informal employment in Romania cannot be understood without recognizing its diverse nature. It is present in many sectors, such as construction, services and agriculture, and takes various shapes and forms, including non-registered firms, false self-employment, workers without labour contracts, tax evasion both by employees and employers and under-declaration of earnings. While some deliberately opt out of the formal system

others have no choice but to use informal employment as a livelihood strategy. (Drechsler, Xenogiani, 2008)

So, two main groups can be identified among those in informal employment: those who work informally because they have no real alternative and for whom informal employment constitutes a survival strategy (non voluntary informal employment), and those who deliberately evade taxes and social security contributions (voluntary informal employment).

The first group includes some forms of *informal work* in agriculture and contributing family workers. The second comprises non-registered firms, or firms which do not register their workers and hire them without labour contracts, firms that under-report their sales and workers who under-declare their earnings and receive so-called "envelope payments" (payments in cash). It should be noted that most people in informal employment around the world are in that situation against their will and informal work provides their only opportunity for generating income. (OECD)

Figure 1. Forms of Informal Employment in Romania

Source: Drechsler D., Xenogiani Th., "The Two Faces of Informal Employment in Romania", p. 24

A second important distinction needs to be made between agriculture and non-agricultural activities. Currently there is no consensus among experts on Romania on whether agricultural activities are indeed "hidden" and should be part of informal employment (Stanculescu, 2006). Some authors (for example, Daianu, Albu) limit informal activities to legal non-agricultural activities, whereas others (Ciupagea) include

agriculture in their definition of informal employment. On the one hand, the plots are registered and authorities are aware of the production (Ghinararu, 2007). On the other hand, normally no taxes are paid on this type of activities, nor are workers engaged in this type of work offered a registered labour contract and social contributions. However, it should be noted that agriculture does form part of the informal sector as employment in this sector is not reported, taxed or in compliance with labour regulations, even though the goods are in some cases sold at the market.

Four main groups of factors can explain the persistence and increase of informal employment in Romania.

First, socio-economic developments, such as economic restructuring and privatisation of state owned enterprises, low or negative economic growth, unemployment, and increased poverty and inequality are among the main reasons pushing people into informality. Moreover, emigration abroad with its links to informal employment is an additional determinant of informal work, as many temporary migrants return to Romania for short periods of time and engage in informal work.

Second, institutional factors, such as labour market regulations and the structure of the tax and social security systems, bureaucracy, heavy public administration and the subsequent corruption also determine informal employment.

Informal employment is also determined by *a number of behavioural/societal factors* such as the culture, the lack of trust in public institutions, the negative perception of the role of the state, partial understanding or underestimation of the benefits derived from social security.

For the last years an important factor which determinate the rise of informal employment is the economic crisis. Thus, the crisis by increasing unemployment, reducing workload, and the measures applied (increase taxes, reduce working time, pay cut) has increased the informal employment.

Those who practice informal (undeclared) work are generally people with low education and training, who have real difficulties finding a job and find work on the underground market an alternative employment, but also people forced to work

under part-time basis and those who prefer activities free of constraints. At the other extreme, but in small numbers, there are super-qualified people who, benefiting from higher education and intellectual capacity are willing for amounts of money, to get involved in organizing and carrying out economic activities such as informal ones.

Undeclared work has multiple causes: higher taxes on employment, labour relations bureaucracy, lack of legislation, unemployment. In general the causes of undeclared work are of economic nature, it offers significant advantages in the short term both for the employee and employer. The employer reduces his costs and has a higher profit if it is committed to the policy of obtaining short-term significant profits to the detriment of the company's development strategies and long-term average. The employee, through the informal employment benefits of higher finances but he is disadvantaged on the long term, because they no longer benefit from wage increases, per diems and allowances, leave, insurance, pensions and benefits.

There are three basic forms of undeclared work:

- *work without a contract* – these are either employees that do not have any written contract with their employer or free lanced professionals that render services without declaring the proceeds from them. Usually, employees do not have a written contract for their additional work, besides their main occupation. The profile of people working without a contract can be rather different. On the one side these might be wealthy, highly educated and well skilled free lancers who can afford to use privately delivered public services (pension and health insurance), do not fear of losing their jobs and have a fairly reasonable understanding that the chances of being caught are low, as is the punishment. On the other – these might be poor, unskilled people who have long lost their jobs, receive under-subsistence social safety payments and do not see any opportunity in finding a job under present institutional conditions.

- *work with a contract, which has hidden clauses*. The additional money as well as the money being paid out without a contract comes out of the 'black boxes' of companies, which are involved in informal activities. It represents a kind of tacit

agreement between the state and some of its citizens. The citizens (employers and employees) would pay the minimum required amount (or the amount they deem appropriate) of taxes and public funds' contributions, while the state would leave them control over the rest of very scarce income. Gradually, the minimum threshold would be pushed upwards to ensure the funds necessary for the proper functioning of the administration, while reflecting the increase in incomes among the citizens. These practices are used in labour intensive, seasonal industries, which are hard for government inspection.

- *household work, which produce is sold on the market. This refers to work in family farms.* As much as 30% of the home production of some items (milk, eggs, meat) is sold on the market, without the transaction being registered. Additionally, especially in rural areas, neighbourhood help against payment is a frequent occurrence. This reflects some socialist time traditions of barter dealing, which have now turned paid but is also a survival strategy for many rural poor who have been left without work, lack capital and have small spots of widely dispersed land.

The phenomenon of undeclared work is difficult to quantify. In Romania in the first nine months of 2008, the informal employment represented 50.8% in the informal economy, and in 2009, informal employment represented 12% of GDP (<http://standard.money.ro/>).

The share of underground economy in Romania's GDP has different values, according to specialized studies, depending on the method used for determination. Thus, according to Kaufmann-Kaliberda model based on electricity consumption, the share of shadow economy in GDP is currently of 26%. This model is based on the idea that economies consume electricity as they develop, as the ratio between the growth rate of electricity consumption and the growth rate of GDP will be the size of corruption in an economy.

According to a study coordinated by Albu Lucian (Romanian Academy), the shadow economy is between 20% of GDP (using the model of energy consumption) and 45% of GDP (based on the monetary model).

The model developed by Friedrich Schneider, the share of shadow economy in Romania reaches 36%. Friedrich Schneider states that "when the global economy is undergoing a recession, more people will be tempted to operate outside the legal framework". Also, Schneider confirmed that there is a close link between the prevalence of cash payments and the size of underground economy in a country.

Employers choose informality in Romania because of high perceived tax and contribution rates, and they get away with it because of insufficient mechanisms to penalise tax evasion. Workers fail to see the link between social security contributions and benefits, and in any case deplore the low quality of public services. Hence they prefer informal employment.

Informality in Romania is above all an expression of the lack of trust in public institutions, the negative perception of the role of the state and the limited understanding of the benefits derived from social security.

For some groups of the population informal work leads to poverty and lives exclusion whereas for others it serves as a safety net. After all, informal employment is an important livelihood strategy for many poor households that have no other income-generating opportunities.

3. Ways of action

Social policies should therefore target those segments of the informal sector while fiscal, labour and other policies should provide the right incentives for people to join formal employment.

Among the measures that may reduce undeclared work there are: reducing the social contributions of employees, the employer tax reduction, the stimulation of SME development. Furthermore, the promotion, development and implementation of training and learning create the conditions for the security of the workplace along their entire lives. The greatest need is training for the less qualified workers. It is necessary to promote that policies which help the most vulnerable groups and offer them the necessary skills and assets to participate in formal work.

For policies to be effective, they have to take into account the dualistic structure of informal employment. On the one hand, active labour market policies combined with well designed social assistance programmes can be used to address informal work for those with no other alternatives. On the other hand, better control, inspection and enforcement are needed for those who choose to be informal. In addition, simplified procedures for business and workers' registration would reduce the cost of formalisation. Overall, improving the quality of public services provided and communicating effectively the benefits of formal work and the costs of informal employment are necessary actions to bring people back into formal work.

Long term sustainable change requires a transformation of people's attitudes and beliefs. More innovative policies, such as information campaigns on the benefits of formal work and the risks of informality can gradually change people's opinions. While these things won't happen overnight, Romania needs to pave the ground with the right policies and regulations now.

Abstract

In this paper we propose a critical reflection occurring mutations in the methodology for measuring a company's performance in the current context of sustainable development.

In this context, companies need to pay more and more attention to accomplishing economic growth and market growth, while ensuring environmental protection and promoting social responsibilities, including the protection of consumers' interests. The need to know and measure non-financial performance is becoming more acute and on this path also the need to define a framework of information and reporting to meet the information needs of stakeholders of the company.

In this paper, we propose a review of key aspects of social and environmental performances, as well as a new dimension of company performance in the current context of sustainable development

Key words: social responsibility, environmental performance, corporate social responsibility.

J.E.L. classification: G39, M10, M14, M21

1. Introduction

The companies of industrialized countries showed, especially after the 50's, their weaknesses in adequately considering the fundamental needs of societies – jobs, food, quality of life, the necessity of the present generation and of the future ones.

However, nowadays, the public and civil society believe that it is not longer sufficient for a company to asserts that its only concern is making profit for shareholders, as long as these are based on operations that fundamentally (either positively or negatively) affect the life of the community. In this context, a growing number of companies adopt, as part of their organizational culture and business strategies, CSR. More and more companies become aware of the fact that they are able to get involved in a sustainable development, leading their operations so that they would achieve both economic growth and market growth while ensuring environmental protection and promoting social responsibility, including the protection of consumers' interests.

In this context it becomes more acute the need for developing a framework for identifying, measuring and reporting social and environmental performance, frame designed to complete the image of a company's overall performance.

2. Literature review on approaches to performance in social and environmental terms

Bunea reviews three international approaches on performance dimensions that performance as follows in the next paragraphs [3]. A first approach mentioned is that of Morin, Savoie & Beaudig (1994), which identifies four dimensions of performance: social - human resources, economic - economic efficiency, political - the legitimacy of the organization against

external and systemic groups - organization sustainability. Another approach that the author mentions is that of the Jacot & Micaelli in the paper *La Performance économique en entreprise* from 1996 supporting the idea de-globalization of performance. According to this two at the level of a company there are four levels of decision (metapolitical, strategic, tactical and operational) and each level has attached a performance level (societal, financial, commercial and physically).

The third approach is the one of De La Villarmois. According to this last author "all models that offer a representation of the concept of performance reach the same conclusion: it is a concept (or construct) difficult to assimilate because of its multiple dimensions" (quoted by [3]). He believes that performance has two dimensions, namely: social, which includes economic efficiency and sustainability, and the subjective one, which includes the legitimacy of the organization against external groups and the value of human resources

From the literature review we noted that in present social performance is an essential component global performance, component that we can not omit this scientific approach. Social performance is part of the company's overall performance in the context of sustainable development, referring to concerns such as company's health insurance, activities consistent with sustainable development requirements, etc., reason for which it requires an analysis of social performance so we can form a complete and relevant opinion on a company's activities.

Analysis of social performance of the enterprise requires the expression of this dimension of performance in terms of social satisfaction, namely human relationships with the company [6]. The term "people" refers in this situation to different categories such as: employees, customers, managers, community in which that company is operating etc. Therefore the concept of "social performance" exceeds the boundaries of an organization and refers to both internal environment and external environment.

Sainsaulieu (quoted by [6]) in his work *Sociologie de l'organisation de l'entreprise*, refers to the following points of social performance assessment [14, 15]:

- The nature of social relations;

- The importance of social conflicts and crises (number, severity, duration, etc.);

- Level of satisfaction of employees (this level can be appreciated by domestic public opinion surveys);

- Absenteeism and delays in service (or employment de-motivation caused by boring or difficult work);

- The social climate of the enterprise (subjective assessment of the ambience at the company's level and its constituent groups);

- Operation of the staff representative institutions;

- Operation, the number and outcome measures of quality circles and participation in decisions.

How can we define social performance taking into account the issues mentioned above? A definition is provided by Savall & Zardet. According to them social performance is defined by the level of satisfaction of stakeholders, achieved through three levels of quality: quality products appreciated by foreign customers, the quality of the operation and management quality especially appreciated by the "internal customers" (employees, managers) [15].

The social dimension of sustainability refers to the impact that an organization has on social systems within which it operates. Now we notice that efforts made in terms of measurement (assessment) and management of social performance are still underdevelopment. The question therefore arises of developing a conceptual framework to enable a quantitative assessment of data on the social dimension of performance and their comparative analysis with either standard or data previously established by other companies that work in the same area, to the extent that these comparisons and evaluations are possible, considering that a part of social performance information is required to be presented in a descriptive manner.

Measuring social performance has the following characteristics [10]:

- Focuses on the company as a whole;
- Requires frequent data collection to allow early correction;

- Compare with an initial state, taken as a yardstick;

- Is externally audited and based on comparable data internally and externally;

- Is accessible and meaningful;
- Is connected with the future goals that the company proposes;
- Should ensure a balance between costs and benefits involved in measuring, reporting and obtaining results.

According to F. Székely and M. Knirsch companies that evaluate social performance are using a series of indicators that capture the following aspects [17]:

- Human rights: human rights issue arises particularly in the poorest countries in the context of globalization;

- Problems at work or those related to employment: it is wanted to assess some aspects of health and safety at work, continuing education, training, industrial relations, wages, benefits and compensation, working conditions and employment, etc;

- Relations with suppliers: is wished to ensure the diversity of suppliers, are assessing company's policies regarding the selection and evaluation of providers including the various contractual arrangements with them;

- Community initiatives: the indicators used should reflect the contributions to local economic development, involvement in the problems of local community, improving personal skills of employees and other matters;

- Corporate philanthropy: it wants to know different information on donations made, in presents interest the total profits before tax and financing of local initiatives by private funds.

The literature which attracted our attention on social performance measurement has been the proposed typology by Iamadi. According to the author societal (social) performance is measured (assessed) by some relevant areas. The author has stated the following relevant areas [9]:

- rules, codes of conduct;
- resources used: this refers to how certain resources are used in the production or various measures to reduce consumption of certain materials (water polluting products);
- internal processes: this refers to various measures of motivation and creation of appropriate social climate for a company, division of work tasks , etc;

- activities: gifts, communicating information to the public / community, social audits and certifications;

- consequences: the author refers to the number of dissatisfied customers processes, the stage of staff training;

- synthetic and combined approaches.

We consider relevant in this area the document proposed by GRI initiative, so we will try to make a brief overview of the four directions of actions presented by it, namely:

- Labor practices and decent work standards;

- Human rights;

- Society;

- Responsibility for the product.

Environmental performance represents the measurable results of the actions of economic agents to identify, quantify and solve their environmental problems in order to achieve environmental objectives and targets set by the Authority of Environmental Protection. The Handbook on Environmental Law Harmonization of the European Union - European Commission Working Document, Brussels, the Second issue from 1998 environmental performance is the measurable results of the environmental management system related to the organization control of its environmental aspects, based on policy, the general and specific objectives regarding environment.

Environmental performance assessment involves a series of technical knowledge (chemistry, physics, biology, etc..) which does not form part of the training of persons involved in business management and evaluation of performance (managers, accountants, auditors, etc.). We see therefore that the evaluation of the environmental dimension of performance is not an easy task, but is a complex one involving possession vast knowledge. Measuring environmental performance is a topical issue which presumes above all the choice and implementation of appropriate assessment tools.

In the context of sustainable development and of the tendency that reporting all dimensions of performance should become compulsory for all companies, not just recommended, companies should be concerned about environmental performance evaluation as well for continuing improvement of this dimension of

performance. We therefore ask the question how to do this last goal. I found the answer to this question to [4,8] according to which continuous improvement in environmental performance is a process of five stages:

- 1) leadership commitment through an environmental policy statement;
- 2) planning objectives;
- 3) implementing actions to achieve simultaneously the goals and objectives of this policy;
- 4) examine and evaluate the results and progress achieved;
- 5) review the environmental management system to improve its effectiveness.

It is thus obvious that an organization should periodically evaluate its environmental performance. Indicators used to assess environmental performance must be measurable, objective, verifiable and reproducible. Following the approach developed in this section, we believe that a company is social efficient only when it controls the impact of its own activities, products and services on the environment. To achieve these goals it needs to review periodically (as necessary) environmental policy and objectives.

3. Social and Environmental Performance between regulatory and necessity

On an international level, United Nations Organization, the European Union and the Organization for Economic Cooperation and Development are three of the most important institutions involved in drawing up a framework that would define CSR and would determine the indicators through which it may be evaluated transparently. CSR is a very broad concept that started to change the world we are living in.

Lisbon 2000 Agenda required the involvement of companies in accomplishing the objectives set for the future of the 2013 European Union. Within the new economic and social space of the beginning of the 21st century, the company becomes the most dynamic force of the new economic institutions on the market. The efficiency of companies will no longer be measured solely based on their economic performances since these are directly influenced by the social and environmental approaches. Functioning in

long term performance parameters, in the context of an increasingly global economy, determines companies to draw up strategies and policies that would ensure *its transformation into a socially and environmentally responsible company*.

The 23.03.2006 communication issued by the European Commission "*Let's make Europe and excellence pole for Corporate Social Responsibility*" underlines the fact that CSR "*...becomes more and more important in the world*", as well as in the European Union (EU). Sustaining CSR development reflects the necessity of protecting the mutual values of the EU and of increasing solidarity and cohesion, in the circumstances in which market economy became established in the majority of countries, thus opening new perspectives for companies. Thus, as it is stipulated in the 23.03.2006 communication issued by the European Commission "*Let's make Europe and excellence pole for Corporate Social Responsibility*", the social responsibility of the company, CSR, becomes an opportunity with major implications for the European economy as a whole, reuniting already active, socially responsible companies with the purpose of working together at the drawing up of the European strategy for economic growth and jobs availability. The 2006 communication issued by the European Commission is, at the same time, a basis for accomplishing the objectives set by the Lisbon Agenda for 2007-2013.

In the present context of business globalization and sustainable development, the informational needs of the participants to the economic life regarding the activity of companies of interest, surpasses the limits of purely financial information reflected in accounting financial statements. In this context it was required the development of a framework (optional for now) of non financial reporting that would include the presentation of some aspect regarding the accomplishing of social and environment objectives within the so called *sustainable statements*.

The most advanced initiatives regarding the development of sustainable reporting consist of Global Reporting Initiatives Sustainability Reporting Guidelines (GRI Guidelines), issued by World Commission on Environment and Development. Over

time, there have been issued three editions of the guide (2000, 2002, 2006 and 2007). The reporting framework GRI has the role of a generally accepted framework by any society (irrespective of its size) for reporting economic, social and environmental performance. Just like in the case of financial reporting that have to observe principle related to opportunity (balance between relevance and credibility), the report cost-profit, faithful presentation of reality etc., so GRI Guidelines demands that the information included in sustainable reporting should respect qualitative principles or characteristics, such as: balance, comparability, accuracy, updating, clarity, credibility.

The performance indicators drawn up by *GRI* can be divided into: economic performance, environmental performance and social performance.

a) Indicators of environmental performance refer to the environmental dimension of sustainable development and the impact of the organization on natural systems (ecosystem, air and water), through inputs (raw materials, energy, water etc.), outputs (products, services, pollution, waste) and the investments in environmental protection.

The grouping of the *environmental performance* indicators is as follows (GRI Guidelines, 2006): *Raw materials; Energy; Water; Biodiversity; Pollution and waste; Products and services; Conformity; Transportation; Global.*

b) Social performance indicators reflect the impact of the company on the social systems within which they function. They are divided into: *Work practices and conditions; Human rights; Society; Product responsibility* [6].

Together with various authors we consider that the Triple Bottom Line approach is more like a metaphor, a concept, since it is extremely difficult in practice to quantify the impact of environment or social factors in order to create such a conceptual framework of reporting the way in which a sustainable reports should be issued. Such a conceptual framework for drawing up a sustainable report could be very useful, from a theoretical point of view, to managers in

their effort to acknowledge the importance they should pay to social and environmental aspects [5].

4. Conclusions

In order to survive in a competitive business milieu, any company has to unfold its activity with the objective of achieving performance. Over time, the approaches referring to business performance, developed together with the unprecedented development of technology that culminated with technologic revolutions thus requiring the adoption of certain models of adequate management. It was required a process of remodeling behaviors and action means. Companies begun to understand and to accept the idea that, in order to succeed in business, one should provide and ensure adequate work conditions, one should provide collective rights for employees and to cooperate with work unions, non-governmental organizations and governmental institutions.

From the study of literature and practice we founded that environmental dimension has received more attention than the social dimension in recent years. We believe that in terms of reporting environmental performance an important aspect is the existence of comparative data for the purposes of presenting information regarding the organization with information on legislative requirements and achieved industry averages. Trying to achieve a certain level of environmental performance determines the application of sustainable development strategies of win-win type for both human society and natural environment.

Detectors For Financial Statement Fraud

Achim Sorin Adrian

Souca Marius-Ionuț

"Babes-Bolyai" University of Cluj-Napoca

sorin.achim@econ.ubbcluj.ro

marius_souca@yahoo.com

Abstract

Through this article we tried to emphasize the main parts that can identify financial fraud within a company's financial statements.

Another point that we wanted to reach is the motivation that prompted them to take action when they reported these frauds.

Key words: fraud, detectors, financial statement, motivation

J.E.L. classification: M 41

1. Introduction

Fraud remains one of the most problematic issues for business worldwide, no matter the company's country of operation, industry sector or size (ICC 2008). Fraud, corruption and illegal practices within big corporations, banks, financial service providers have contributed to the current crisis, at a large extent (Maarten De Schepper, 2009). Due to fraud, companies suffer not only direct economic losses, but also the risk of bad publicity (Arahal et al.).

Over time we have dealt with fraud amounting to billion dollars that took place before our very eyes. There are striking cases of Enron, AOL, and Xerox in the United States of America, Parmalat and British Telecom in Europe. These cases distinguished by their magnitude and the long period that took place.

The high incidence of fraud is a serious concern for investors as fraudulent financial reports can have a substantial negative impact on a company's existence as well as market value. For instance, the lost market capitalization in SUA of 30 high-profile financial scandals caused by fraud from 1997

to 2004 is more than \$900 billion, which represents a loss of 77 percent of market value for these firms (Glass Lewis & Co. 2005 quoted by Hogan et al. 2008).

It is interesting to see who should detect these frauds. At a first glance it seems that ones in charged with governance have the principal responsibility in respect to fraud detection. They are "traditional detectors" whose main task is to ensure the company against frauds.

When the detection of fraud by those in charged fails, or worse, those in charged with governance are involved in committing fraud, as often happens, what should be done? The solution comes from within and from outside the organization. Lately, Hill came to the so-called non-traditional detectors, represented by employees, financial analysts and journalist. They are called non-traditional detectors, because they have no legal obligation to disclose fraud, yet they do so.

2. Fraud and financial statement fraud

According to Oxford Dictionary fraud represents "wrongful or criminal deception intended to result in financial or personal gain".

Singleon et al. (2006) define fraud as a generic term that embraces all the multifarious means which human ingenuity can devise, which are resorted to by one individual, to get an advantage over another by false representation. No define and invariable rule can be laid down as a general proposition in defining fraud, as it includes surprise, trickery, cunning, and unfair ways by which another is cheated. The only boundaries defining it are those witch human knavery".

Next, Elliott and Willingham (1980) introduce "The deliberate fraud committed by management that injures investors and

creditors through materially misleading financial statements”.

Or the Statement on Auditing Standards (SAS no. 99), *Consideration of Fraud in a Financial Statement Audit*, states that three conditions are generally present when fraud occurs. First, there is an *incentive* or a *pressure* to commit fraud. Second, circumstances provide an *opportunity* for fraud to be perpetrated (e.g., weak controls or ability of management to override controls. Finally, there is an *attitude* or *rationalization* for committing fraud (Hogan et al. 2008).

3. Corporate financial fraud detectors

According to a study by Dyck et al. (2007) resulted that the key parties in the discovery of fraud are: employees (19 % of the cases), non-financial market regulators (16 %), media (13 %), financial analyst and auditors (14 %), short seller and equity holder (9 %) and SEC only 6 %.

Below, we will make a brief analysis of each party which can be a determining factor in detecting fraud within the company:

A. Internal

i. Corporate Governance

The international audit standards require governance, which have an important role in preventing and detecting fraud. They stipulate that "those charged with governance of an entity have a responsibility to ensure, through oversight of management, accounting systems and integrity of financial reporting entity and to ensure that appropriate controls exist, including for monitoring risk, financial control and accordance with the law" (ISA 240).

The existed problem here, as it was already showed by many practical cases, is the governance's involvement in frauds, therefore, in such cases we must rely on other stakeholders within or outside the company, who could make disclosures of information.

i. a) Management

Also in the international audit standards it is set out the obligation of management in preventing and detecting any fraud."This responsibility includes implementing and ensuring a continued operation of the

accounting systems and internal controls, which are designed to prevent and detect fraud and errors. Such systems reduce but not eliminate the risk of misstatements, whether caused by fraud or error. Consequently, management assumes responsibility for any remaining risk" (ISA 240).

i. b) Internal auditors

This time the international internal audit standards come with details on the obligations that internal auditors have. In accordance with the 1210.A2 MPA rule of implementation of the internal audit standards it is said that: "internal auditors should have sufficient knowledge to identify any signs of fraud ". In terms of detecting fraud (MPA 1210 A2-2), the internal audit is to help members of the entity to carry out its functions effectively providing them with analysis, evaluations, recommendations, advice and information on the activities examined.

ii. Accountants

Accountants can play a critical role in the early detection of fraud within organizations (Nitsch et al. 2005 quoted by Kaplan et al 2010). Accountants are usually the first to be aware of "any unethical, immoral or downright illegal" transactions within a company (Appelbaum et al. 2006). Due to the fact that they take part in the middle of the actions, they are able to make disclosure when the company finds that irregularities occur. Employees clearly have the best access to information. Few, if any, frauds can be committed without the knowledge and often the support of several of them. Some might be accomplices, enjoying some of the benefits of the fraud, but most are not (Dyck et al. 2006).

Cases of integrity warnings coming from the employees are numerous. For example, two whistle-blowers, Cynthia Cooper and Sherron Watkins, played significant roles in exposing accounting frauds at Enron and WorldCom, respectively, and were named in 2002 "persons of the year" by Time Magazine (Bowen et al 2010). In Europe we can point out where Neil Mitchell, executive director at software developer Torex Retail Office in reference of some irregularities in

their accounts. He has been ousted, but he required to maintain his job using the whistleblowers protection law.

To encourage these revelations coming from the employees, some legislation guarantees compensation and rewards for them. Under the Federal False Claims Act, citizens who help uncover fraud in government contracts or government programs may be awarded a portion of the recovered funds.

B. External

i. Media

The media and press portray almost on a daily basis incidents related to illegal, fraudulent, or unethical behavior. It has become almost common place to read or hear about such activities as insider trading, bribery or kickbacks, stealing company funds or properly, sexual harassment, and negligence resulting in environmental disasters (Kennan 2002).

Journalist may have much to gain from the discovery of fraud. Their reputation will rise thus facilitating their career ascent.

But the problem is that the journalists often perform no better than regulators in facilitating the efforts of whistleblowers (Macey 2007). Journalists have indirect access to data from the company. They could use the disclosures made by employees to make them public in this way, becoming their voice. Between the media and disclosures made by employees there is a connection.

In Europe is famous the Kakraman Salyev case. As president of a non-governmental organization, he wrote an article in 2001 about the acquisition of shares in a local energy producing company, which was at the time a part of the state holding Edinye Energeticheskiye Systemy Rossii, by a group of Moscow-based firms. He described the purchase as a crooked deal and alleged that a high-level official from Moscow, one of the leaders of the pro-government political party, was behind the transaction. The editor-in-chief of a municipally owned newspaper, Vecherniy Magadan, agreed to publish the article in its issue of the 2nd of November 2001. Later the chief editor was dismissed from his office and then the distributed copies of the newspaper containing the article

had been destroyed. However the situation was eventually resolved, it was reinstated in office and the article was published.

ii. Financial analysts

The finance and career concern views suggest a significant role for analysts in fraud detection. As agents of investors holding residual claims (for both equity and debt), they specialize in interpreting company information into insightful analysis. While analysts do not receive direct monetary compensation for revealing fraud, they can benefit indirectly: through enhanced reputation and career prospects (e.g. Fama (1980), Hong and Kubik (2003) quoted by Dyck et al 2007).

As an example, we could choose the WellCareHealth Plan INC of Tampa, US. For years, the company seemed to defy all expectations achieving ever higher returns from one year to another, from providing life insurance to elderly and poor persons. Between 2004 and 2006 the company tripled its earnings, situation attributed to the efficient organization of the company. However, Sean J. Hellín financial analyst who reviewed the company between 2002 and 2007 said that this increase is based on a large scam. Involved in a federal investigation, he worked undercover for 18 months in the company, gathering evidence and helping them to debunk the whole scheme of the business.

iii. External auditors

Auditors have access to internal company documents and it is assumed that they should be the first to notice any fraud within a company, but often is not the case.

Current professional standards and authoritative guidance require auditors to provide reasonable assurance that financial statements are free from material misstatements, whether caused by errors or fraud (Hogan et al 2008).

An audit conducted in accordance with ISAs is designed to provide a certification that the financial statements are free from significant distortions caused by fraud or error.

From what we see, auditors have a set standard requiring that the auditor should

clearly identify any fraud. However, many times this does not happen.

In a study Made by the Association of Certified Fraud Examiner (ACFE), of 1,843 cases of occupational fraud in 106 countries in 2008 and 2009, 76% of the organizations implemented an external audit of financial statements as an antifraud control measure, but just 4.6% of the frauds were initially detected through an external audit.

A good example of the identification of frauds by auditors is Accredo Health INC case. Auditor Ernst and Young concludes that \$53.3 million of accounts receivables acquired in its 2002 purchase of the special pharmacy unit of Gentiva is uncollectible. Accredo stock drops 40% on the announcement. (Dyck et al 2006).

Although in theory it is assumed that any fraudulent practices identification should increase the reputation of auditors or of the audit firm, in practice this does not happen. There are eloquent the big implications of financial fraud audit business: one example is the audit firm Andersen, which audited the company Enron, the latter deprived of the right operation.

Also from practice we realize that for an audit company is very harmful to audit a company that has a tarnished reputation. That's why the audit firms choose to remain silent when they encounter illegalities, because from any disclosure not only they will lose a customer, but their reputation will suffer as well.

iv. **Customer**

By imposing late fees and penalties on payments to its First USA credit card without proper controls in posting payments, Bank One induces high attrition and generates massive numbers of complaints to the Office of Comptroller of the Currency. The Comptroller's office, forces the firm to disclose its troubled credit card operations and revise its earnings downward. The internal pressure leads to a shakeup of management and the board and a \$725 million restructuring charge. In final settlement, Bank One settles for \$39.9 million (Dyck et al. 2006).

v. **Regulators agents**

Post-Enron investigations by the SEC uncover round-trip trades made by CMS. In one year, round trip trades accounted for \$4.4 billion, 98% of CMS's revenue. Investors were misled not only to the value of CMS, but also as to the liquidity of the wholesale electric market. CMS restates earnings for two years and the SEC charges CMS and three executives. CMS settles with shareholders for \$200 million (Dyck et al 2006).

vi. **Short seller**

In a study realized by Karpoff et al. (2008) it is said that short seller play an important role in helping to uncover financial misrepresentation. They provide evidence on short sellers' effects by examining short selling around the public revelation that firms have misrepresented their financial statements. Such revelations are material events, as they are associated with a one-day share price decline of 18%, on average. They find that short sellers do indeed anticipate such revelations, as abnormal short interest builds steadily in these stocks during the 19-month period before the public revelation. The amount of short selling increases with the severity of the misrepresentation, indicating that short sellers are sensitive to the characteristics of the misconduct. These results imply that short selling activity, at least in firms that violate financial reporting rules, tends to be informed rather than manipulative.

4. Conclusions

The main responsibility in detecting fraud within any company is through corporate governance. Good corporate governance provides a good internal control, an internal audit committee and independently, well-organized and better oversight of management activities. In this way one could get a high degree of insurance against risk of fraud and the detection of it.

But, the problem occurs when governance is involved in committing the frauds. From the moment enter the so-called non-traditional detectors such as financial analysts, employees and journalists. They,

after what we saw, are the main actors in the disclosure of financial fraud, even if they, at a first glance, it seems that have much to gain from these disclosures.

The benefits available to those who disclose frauds are most often small or nonexistent. Thus, analysts, employees, auditors do not have much to gain from these revelations, but on the contrary. Thus, employees are likely to suffer various reprisals, auditors are likely to lose important customers, their reputation will suffer because of the association between them and various fraud, analysts do not get any financial gain, only their reputation will benefit; the journalists seem to have more to gain: they will provide better career ascent. In a nutshell, when we have the wolf guarding the sheep, we do not only have to rely on so-called non-traditional detectors so, therefore, governments who want a healthy economy must take measures so as to encourage and to protect them, which unfortunately is not happening yet.

The Relation between Corporate Governance and Financial Statement Fraud

Achim Sorin Adrian

sorin.achim@econ.ubbcluj.ro

marius_souca@yahoo.com

Abstract

This article aims to highlight the relationship between corporate governance and financial statement fraud. It also emphasizes the characteristics that would be needed for good corporate governance so that it could prevent any type of frauds.

Key words: fraud, corporate governance, financial statement,

J.E.L. classification: M 41

expect incidents to occur most often in an environment characterized by irresponsible and ineffective corporate governance (Rezaee, 2002).

An understanding of what corporate governance is and how it works may contribute to an awareness of how attributes of this monitoring structure may be associated with the incidence of fraudulent financial reporting. It is anticipated that the monitoring aspects of corporate governance, may prove to significantly differ between fraud and non-fraud companies (Bourke p.6).

1. Introduction

We have witnessed in recent years to a variety of financial fraud. Proofs are plenty, for example: AOL, Enron, AIG, Satyam Computer Services in the U.S., Torex, British Telecom and Parmalat in Europe. It is believed that one of the issues that led to the production of these frauds was poor corporate governance (Zhang 2006, p.1).

Corporate governance and accountability within a company are linked. Financial accounting provides financiers with the primary source of independently verified information about the performance of managers. Thus, it is clear that corporate governance and financial accounting are inexorably linked (Sloan p.2).

Managers justify their activity by financial results. When the results obtained in the financial statements do not match the expectations of managers, they, along with others as part of government will be tempted to manipulate the results. What afford them to do that? A weak corporate governance (Bower et al. pp. 1247). Because financial statement fraud is typically committed by the top management or employees, one would

2. Corporate governance

The term "corporate governance" derives from an analogy between the government of cities, nations or states and the governance of corporations. The early corporate finance textbooks saw representative government as an important advantage of the corporation over partnerships but there has been and still is little agreement on how representative corporate governance really is, or whom it should represent (Bech et al. p. 2).

Corporate governance refers to the structures and processes for the direction and control of companies. Corporate governance concerns the relationships among the management, Board of Directors, controlling shareholders, minority shareholders and other stakeholders. Good corporate governance contributes to sustainable economic development by enhancing the performance of companies and increasing their access to outside capital.

The role of corporate governance is to reduce the divergence of interests between shareholders and managers. The role of corporate governance is more useful when managers have an incentive to deviate from

shareholders' interests (Roodposhti and Chasmi 2010).

Over time there have been several attempts to define corporate governance. The Public Oversight Board (POB 1993) has defined corporate governance as follows "those oversight activities undertaken by the board of directors and audit committee to ensure the integrity of the financial reporting process". Bourke (2006 p.28) say that corporate governance is used to deter any conflict of interests between shareholders and managers that may result in fraudulent behavior causing a reduction in shareholder wealth.

As an interpretation of the definitions given above we can notice that the role of the governing corporate is a means that ensures correctness of financial statements, in this way protecting the interests of shareholders in the company.

Karamanou and Vefas (2005 p.454) suggest that corporate governance structure, as expressed by corporate boards, audit committees, and ownership characteristics, is associated with financial disclosure decisions.

3. Financial statement fraud

Fraud was a very serious, underrated, and somewhat ignored threat to private and public entities for most the nineteenth century. As a consequence, it prospered relatively undeterred and has cost many entities enormous sums of money (Silverstone and Davia 2005). Fraud consists of knowingly making material misrepresentations of fact, with the intent of inducing someone to believe the falsehood and act on it and suffer a loss or damage (Louwers et al., 2007 p 68).

Bourke, 2006, p. 21 defined fraud in the financial statements as follows "the conscious effort by management or other members of the governance body to sanction, or otherwise support, the production of materially incorrect financial reports".

Financial fraud regarding the financial statements is represented by a set of financial statements that would need to be in accord with an accepted set of standards, but they are not. In a report published by COSO, the

profile of companies involved in financial fraud is as follows:

- They were small to mid-size less than 59 million in revenues or assets (large companies should not be excluded, there are in less number, but the frauds are most resounding);

- They were often in a net loss or break-even position in the prior to the beginning of the fraud;

- Concentration were centered in the technology, healthcare, and financial services industries;

- The COEs and CFOs were involved in the fraud;

- Boards and audit committees were very weak and owned a significant share of company;

- The company manipulated revenues and/or assets; some frauds involved only disclosures;

- There were dire consequences for the company, often bankruptcy (In a report commissioned by the Treadway Commission, entitled „Fraudulent Financial Reporting: 1987-1997, an analysis of US Public Companies, the Committee of Sponsoring Organisations of the Treadway Commission (COSO) analyzed the characteristics of approximately 200 financial statement fraud cases involving US public companies to learn about the nature of the companies involved, the nature and size of the fraud, and parties responsible for the fraud (Silverston and Davia, p.10, 2005))

4. The Relationship between corporate governance and financial statement fraud

A good corporate governance will ensure a greater control over the accuracy of the financial statements. In contrast, a poor corporate governance will have less control over such information in the financial statements. What makes a good quality governance to be considered and what is not?

(Karamanou and Vafes, p. 2, 2005) suggest that corporate governance structure, as expressed by corporate boards, audit committees, and ownership characteristics, is associated with financial disclosure decisions, and specifically they hypothesize that effective governance mechanisms are

positively associated with the quality of financial disclosure practices.

Next we will analyze each part to see how corporate governance affects the quality of financial statements:

a) Audit committee

Internal audit is an important part of the corporate governance structure within an organization. Corporate governance includes those oversight activities undertaken by the board of directors and audit committee to ensure the integrity of the financial reporting process (Public Oversight Board 1993)

A study by Coram et al. (2006) showed that a functioning audit committee is more likely to determine existing fraud. It is also shown that having some insourcing is more effective in detecting and reporting fraud than completely outsourcing the internal audit function.

Karamanou and Vafes (2005) find evidence that the market reaction to management forecast announcements is related to board and audit committee characteristics, especially when the forecast releases good news. This evidence suggests that investors have greater confidence in good news forecasts that undergo the scrutiny of more effective boards and audit committees. The Audit Committee is influenced by many factors. These influential factors we have described below.

Firstly, it is very important the independence of the internal audit Committee members. "Skouen and Wright (2006) found that as the proportion of audit committee members who are independent increases, the probability of financial statement fraud decreases. They define an independent audit committee member as a member who is not a current employee of the firm, former officer or employee of the firm or related entity, a relative of management, professional advisor to the firm, officers of significant suppliers or customers of the firm, interlocking director, and/or one who has no significant transactions with the firm (Robinson, 2002) "(Shamhi, 2009, p.26).

Secondly, of a major importance there is the independence of the audit committee director. In a study conducted by Agrawal and Cgadha (2003) find that the probability of restatement is lower in companies whose boards or audit committees have an

independent director with a background in accounting or finance.

Another factor that could influence a possible fraud is represented by the auditors' contracts. In another study conducted by Person (2005) concluded that motivating the audit committee members by providing a long term contract can be very useful for improving corporate governance. Tying the future for a longer period of time to the company they work they will think twice before risking their future.

b) Board of directors

The Board of Directors is a very important component of corporate governance. Next, we showed which factors influence the actions of the Board of Directors.

One influential factor that we might note here is the size of the Board of Directors. A board of directors with a large number of members is more difficult to control than a committee of directors which has up to seven or eight members (Jansen 2003 quoted by bronzes in 2009, p.4).

A second factor that may influence the accuracy of financial statements is the number of directors from outside the entity. In a study by Beasley (1996) is concluded that companies that have experienced financial fraud have a higher percentage of directors independent of the organization.

A third influential factor is the conflict of interest that may arise; the Board of Directors should clearly stipulate that the chairman of the Board of Directors cannot occupy the position of executive director. Combining the positions of chairman and CEO confers greater power to the CEO (Shivdasani and Zenner 2002). Unfortunately this is often not the case; we can speak of an unethical management (Dunn 2004 quoted by Bourke 2006 p. 47).

Another factor is the supremacy held by directors in the entity. If they have total control over the company, this will lead to an undermining of property held by shareholders. The supremacy of inside members of the board of directors is a factor that can create conditions for the occurrence of wealth transfer from shareholders to managers of the firm (Fama, 1980).

A fifth factor that should be taken into account is the number of committees in which a person may be appointed director of

the entity that should be played. The findings collectively suggest that directors with multiple board seats are generally likely to be individuals with strong reputations whose services are in demand by many boards (Shivdasani and Zenner 2002).

One other interesting feature that characterizes companies involved in fraud is the number of board of directors meetings. Vafeas (1999), after analyzing the frequency of meetings of the Board of Directors concluded that the companies involved in the frauds had a frequency of these meetings higher than the other companies. And why is that? Shivdasani and Zenner (2002) said that frequent meetings might also distract the firm's managers from their day-to-day operational responsibilities and may deter the board participation of some of the most desirable directors with other time-consuming responsibilities.

c) Shareholders

Wang (2005) shows that even when the manager's interest is perfectly aligned with that of shareholders, fraudulent behavior can still emerge, because incumbent shareholders may find it advantageous to defraud prospective investors. Good corporate governance will not completely prevent fraud if it is under the control of existing shareholders.

Shleifer and Vishny (1997) argue that concentrated ownership is a key element of a good corporate governance system because large shareholders have high incentive and power to impose effective monitoring over the management (Wang 2005, p 51). On the one hand, the presence of block holders may curb the discretionary behavior of the managers, incite them to adopt profitable strategies and disclose relevant and reliable information (Klai 2011 p.160)

5. Conclusions

After what we saw there is a strong link between corporate governance and financial fraud cases. Managers have every incentive to obtain the best results because their compensation depends heavily on this. When these results are not desired, they will be tempted alone or with others as part of the governance of the company to handle these results. After what we have seen these

practices can be detected or even more important: prevented.

A good strategy for detecting and preventing fraud in the financial statements represents establishing responsible corporate governance, vigilant board of directors and audit committee (Rezaee, 2002, p. 81).

As far as we have noticed in a well-established corporate governance it is very important the independence that the senior members of management must have. Also, it is crucial for the audit committee director to be independent of the entity, if possible. Another thing to be underlined is the number of board of directors. After what we saw, a small number of executives provides a better control over the entity.

Good governance requires the implication of the states, so as to create a strong law to regulate this area. The frauds from the U.S. or Europe - where there were lost billions of dollars - should be good examples, in order for us to learn from them.

Aspects of the Financial Analysis

Achimescu Georgeta
Verișan Cristina-Alina

"Spiru Haret" University, Faculty of Financial and Accounting Management Constanta
georgeta.achimescu@spiruharet.ro
cristina.verisan@spiruharet.ro

Abstract

The analysis, as a general research method of the nature and society phenomena represents the breaking down of those ones in their component parts in order to be studied and discovered causal relationships. The economic analysis concerns the economic activities consuming resources and generating results. The financial analysis, as all the direct final professional disciplines, is in perpetual development, sustained by a lot of several factors, the most important being the methodology and the technique. The financial analysis, above all, is a subject of interpretation, especially of the information with accounting provenience, which requires restatement for adaptation to specific needs.

The financial analysis deals with aspects from the point of view of the different partners of the enterprise, as well as in terms of the appropriate categories of information.

If, following the financial analysis, the financial analyst follows the company's financial health, the „pathology”, but also the „symptoms” and the necessary „remedies” in order to treat them, respectively the chances of „healing” and the relapse risks, we can say that the financial analysis is an art of the description and of the interpretation, allowing the evaluation of the financial potential, the placement of the company in the economic sector, the expression for each strategic option of the future performances and the realization of a comparison between the needed and the available resources.

Key words: performance capable, the overall loss risk, financial risk, exploitation loss risk, capitalization.

J.E.L. classification: G0

1. Introduction

The area of the financial analysis is very broad, referring to the analysis of the performance capacity of the company, to the analysis of the loss risk, to the static and dynamic bankruptcy risk, but also to the use of modern methods and procedures and of the expert systems of financial diagnostic of this field.

As a practical activity, the financial analysis needs to scroll three stages namely:

The first stage involves the collection and the detailed research of all the data and the information needed for the analysis. For this purpose, the analysis uses a system of data and information, which should reflect completely the situation of the company appealing to more information sources, which can exist in or outside the company. The internal source are coming from the informational accounting, financial and statistic subsystem of the company and refers to the data of the financial and treasury management accounting, to different statistic reports as to a lot of other non-accounting information. The external sources are coming from outside the company and include general information on economic, financial and monetary terms, information regarding the activity domain of the company, but also other legal and legislative information.

The second stage includes the general verification of the data and information extracted from various forms both in terms of their comparability and in terms of the compliance with the laws in force. At this stage the material is made to simplify the analytical and numerical values and the rounding of the numerical values and the elimination of the small, insignificant series will be realized.

Finally, the last step supposes the proper analysis by applying its own methodology, at the end of this one conclusion should be drawn and a final report of analysis is prepared, which is attached to the documents of synthesis for different internal and external users and this fact gives the analysis the expedience for the management decision. [3]

2. Concepts and methods of research of the financial analysis

Like any scientific discipline, the financial analysis is defined through the object of study and through its own method of research.

The subject of the analysis is generally the economic-financial activity of the economic entities at the micro and macroeconomic level it researches from the point of view of the results of the utilization of the human, material and financial resources, in order to discover opportunities and to value the possibilities of improvement in the future. The way of the analysis is in the sense of the real evolution of the phenomenon starting with the production process in the direction of its final results or it can be a opposite one starting with the results of the finished economic process in the direction of the consumed resources. In every variant of approach the analysis aims the measurement of the results achieved in the economic-financial activity with the consumed resources, comparing this way the effects with the effort with the purpose to evaluate the efficiency.

The research methods of the analysis show the way to be followed in order to know rationally the economic phenomenon and include a series of steps, processes and techniques used to obtain the purposed objective: to establish and to quantify cause-effect relations in the economic-financial activity. For this purpose, using the analysis and the synthesis as methods aiming the breaking down of the researched object into parts and respectively their assembling into a whole, the financial analysis crystallized its ways of knowledge in its own method in four stages [1]:

The first stage – comparing phenomena – is a method of quantitative analysis that seeks a deviation indicator towards the reference value taken as a basis of comparison.

The next stage – the decomposition – is a deductive method of quantity analysis from general to particular, from whole to part and allows the detail and the separation of the factors determining the indicator which assures this way the localization of the causes through the factors to be selected and interpreted. Before the decomposition of the factor, it should be knew from practical experience what factors determine this indicator and how it makes progress.

The third stage – to establish the influence of the factors – includes more quantitative methods of quantification of the action of every factor on the studied indicator, which mean the most important element of the analysis. This stage represents the unity of two different sides respectively the precision of the system of cause relationships between the factors and the indicators and the quantification of the influence of these factors on the deviation of the indicator.

The last stage, of synthesis supposes the generalization of the results, respectively the transition from particular to general and aims the bringing together of the parts studied on previous stages into a whole. The generalization retains what is essential and typical, the main elements being separated from the minor key.

3. Methods and procedures of the financial analysis

The financial analysis is not an exact science but a contextual discipline, which uses the comparison as the main tool of investigation and verification. Although the figures don't speak for themselves, situated in a particular context and confronted with other, related to the politics of a company, they could be made to speak [2]. If the financial analysis was reduced to the methods of examination of the accounting documents which envisage mainly the elaboration of the results account and of the balance, in the present the domain of study of this one was considerably extended, which has forced the diversification of the methods and processes used in order to achieve its objectives.

The methods of the traditional financial analysis are:

1. The comparison of the financial statements in function of the reference criteria: there are comparisons in time and comparison in space. The comparison in time over several years admits the evidence of the tendency of some analysis indicators of the analysis (increase or decrease). The comparisons in space made between companies of the same area admit the appreciation of the position of a company in the industry and to evaluate their strengths and weaknesses relative to competition.

2. The method of analysis through RATIO – in the financial analysis, the English word RATIO (of Latin origin RATUS), which means calculated, is synonymous with the terms coefficient, ratio, percentage, and rate. RATIO is an economic rapport or financially significant between two absolute values which represents two items or groups of balance sheets from the result sheet or from the balance of results. The report can be expressed as a percentage, number of days or number of years or in form of coefficient in order to obtain more meaningful information as they can provide as absolute values of some account sizes. The RATIO ensemble includes a number of representative indicators of financial analysis that serve three purposes, namely [3]:

- The performance measurement as consequences of the decisions on investments and financing;
- The effectuation of comparisons over time in order to study the evolution of the financial situation;
- The situation of the company in its own professional milieu by comparing their rates with those averages of similar business.

3. The specific analysis method – in function of the purpose, the financial analysis can use a number of specific methods adapted to situations for the study of the liquidity, profitability and risk, the study of the activity of the company, of the financial structure, of the chains and cash flow rates.

4. The stages of the financial analysis

The effectuation of a large financial analysis, which can lead to a financial diagnostic, supposes the following steps:

1. The preliminary stage supposes the presentation of the information regarding the activity domain of the analyzed company, the evolution of the turnover in the last 4-5 years, the rate of return expressed through the rate of the growth of the net profit, the rate of the benefit of the own capitals, the risks, the share of total borrowing and short term debts and that to have a first representation of the company.

2. The examination of the financial situations supposes:

- The analysis of the results;
- Financial balance and functional analysis;
- Panel study and the cash flows.

3. The formulation of the financial diagnosis – following the summary of the financial analysis in synthesis will be presented the strengths and the weaknesses of the company. The results of the financial analysis will be valued differently depending on the user, but generally will seek to answer the questions of a financial, economic, fiscal and legal nature [4].

A particular attention will be given to the financial aspects, such the demand of credits on long and short term, purchases of actions, issuance of new shares, making new investments. The conclusions of the financial analysis can be valued in the elaboration of new studies of feasibility or of necessary evaluation for different purposes.

A conclusive indicator, which occurs in the calculation of the rates of performance, is the added value, an indicator to be interpreted with caution, realizing its calculation in two ways:

1. The synthetic method, which says that the added value is equal to the difference between the production of the exercise plus trade margins one side and the intermediate consumption of goods and services from third parties on the other side. Through its containing, the added value is one of the significant indicators of the activity of the company and that because the sum of the values added of all economic entities are national gross domestic product.

The added value as an *instrument of analysis* allows the appreciation of the economic-financial performances of the company and namely: the real economic strength of this one; the contribution of the factors at the creation of its own wealth; the contribution of the company at the creation of the gross domestic product. The added value is a way of appreciation of the size of a company, more significant than the turnover. Used in intra-comparisons, the added value reflects the structural differences between similar companies in terms of the reports between the inputs incorporated in the economic activity.

The added value as a *way of administration*, it characterizes the exploitation of the company being used in the administration control and to determine the value of the added taxes as a indirect tax.

2. The analytical method of calculation of the added value is a method of repartition because it supposes the sum of the structural elements of the recently created value, respectively: staff, bad taxes, financial expenses, the amortization of assets, net profit. Specifically, the added value produced by the company is shared between all participants in the life of the production company:

- The staff of the company through the staff expenses given directly in the form of the wages and indirectly in the form of the insurances and social protection, as well as through the participation of the employees in profits;
- The capital contributions through the debts paid to the creditors of borrowed resources and through the dividends paid to the shareholders for the equity permanent capitals, the analysis of the account results;
- The state through taxes and tax receipts;
- The company itself through the compensation of the depreciation and of the use of fixed assets by reserves and provisions as well as self-financing their development.

The added value structured this way is a performance indicator that allows the appreciation of the efficacy of the activity of the company for a given activity [5].

5. The profitableness – a criterion of performance

The profitability is company's ability to profit. Moreover, the objective of every economic entity is to respond to the expectations of the participants at its life as well as the development of the value in order to assure its own development.

The realization of this objective is the condition of development of a rentable activity that can allow the compensation of the consumed production factors and of the capitals used whatever their origin could be. Every business involves a certain investment, which has as consequence the result of the investors. When the result is higher, new available sources can be formed for other investments in different purposes such as: the stimulation of the partners; the insurance of its own business development; the creation of reserves.

The profitability results from the measurement and comparison of the effects, respectively of the income with the efforts made, with the expenses made in order to obtain them.

The analysis of the profitability of a company is realized based on the profit account which includes the economic flows that reflect the creation of the wealth based on the overall spending and revenue, whose difference corresponds to the result, which can be positive or negative, respectively benefits or losses.

The presentation of the result account in accounting and financial situations is based on two conceptions:

a. *the conception after nature* – it supposes the account of result in tabular form, the debit representing the expenses, and the credit having the benefits, the balance of the credit or of the debit indicating the benefits, respectively the loss.

b. *the conception after the functions* – based on a logics of the costs on the functions of the company which allows the presentation of the profits and expenses in form of a list in accordance with the expenses attributed to the different activities, respectively production, sales, finance.

The study by functions of the profit account allows the determination of the margins of results in five levels, namely: the result of the exploitation, the current result,

the financial result, the net accountings result. This conception of presentation of the account of profits and loss is accepted from international accounting standards as well as from European objectives. The determination of the result represents a preamble for the accounting analysis of the financial analysis and of the evaluation of the company.

Starting from the result we can define the capacity of self-financing of a company and the concept of cash flow at the origins of the treasury as a major object of the analysis of the financial situations in order to determine the degree of competition of the company [6].

6. Conclusions

The financial analysis is considerate one of the demarches of a global diagnostic, which envisages appreciating the value, in large terms of the company. Such a diagnostic has generally three important phases: a phase of evaluation of the entire potential of the company, human, commercial, technical, a phase of competition positions of this one in the milieu and a phase of evaluation of its strategic options.

As a specific investigation method, the financial analysis brings its contribution to the realization of each of the three phases. The financial analysis allows the evaluation of the potential of a company, of the financial competition power, of the capacities of debt and repayment of debt, of the position of this one in its financial milieu in relation with the banks and the financial market through the confrontation of the characteristics of the company with the laws given by this milieu, the appreciation of the degree of adequacy between needed and necessary resources.

The traditional financial analysis can be completed with new elements if the computer assistance is envisaged, which, near the technical aspects involve the adaptation of the statistic methodology of the analytic approach to the problem of the evaluation based on information provided by accounting and not only.

The Financial Diagnostic – Profitability and Risk

Achimescu Georgeta
Verișan Cristina-Alina

"Spiru Haret" University, Faculty of Financial and Accounting Management Constanta
georgeta.achimescu@spiruharet.ro
cristina.verisan@spiruharet.ro

Abstract

The financial diagnostic calls, especially the study of liquidities, of the financial structure, of the profitability, but also of the other aspects such as the risk, the development of the company and other. With this purpose, the financial analyst should study the financial situations and the aggregation of this ones with general information on economic, fiscal and monetary, legal and economic and those referring to the economic activity of the domain of activity of the entity. A right financial diagnostic can be established by a much boarder approach, including a preliminary study on the environment. The principal objectives of the financial diagnostic are regarding especially the evolution of the risk management, being sometimes restricted to the formulation of opinions on the economic-financial health situation of the company regarding the shareholders, the investors and the business keepers and creditors, the borrowers. Starting from the objectives of the financial diagnostic, we can distinguish three types of financial diagnostic, namely: the financial diagnostic of the shareholders, the financial diagnostic of the leaders of the company and the financial diagnostic of the creditors.

Key words: risk degree, profitability degree, inflation risk, reputation risk, efficiency risk

J.E.L. classification: G0

1. Introduction

The term of profitability has a relative character. The capacity to have monetary results cannot be judged apart of the means employed to achieve them. That's why the profitability analysis is not restricted to the

investigation of their absolute indicators, but also of the relative ones, obtained through the reports of results at the means engaged or consumed for the development of that activity.

The profitability is one of the most synthetic forms of expression of the economic-financial efficiency of the company, respectively of all the production ways used and of the labour of all the stages of the economic cycle: purchasing, production and sale.

The financial diagnostic means not only the actions of discovery of the risk, but also of the potential of the company so that we can understand the past situation and the prevision of the future evolution, to measure and to interpret the results of the past in order to prepare the future economic and financial situation of the company. All the information will be used for a first investigation of the aspects referring to the function of the entity, at a dynamic approach of its behaviour, at an appreciation of its results in correlation with the characteristics of the concurrence environment, at an evaluation of the degree of risk and profitability.

2. Delimitations regarding the financial diagnostic

After the expression of Bernard Colasse, the financial diagnostic is "an experimental approach, whose development varies as well as the analyst follows the objectives strictly defined or seeks the diagnosis in a extensive manner"[1].

The financial diagnostic is approached from the point of view of the shareholders as well as from that one of the creditors.

In order to establish the financial diagnostic of the shareholders it is necessary to analyze the many problems of growth, of

profitability, of financial balance and even of risk, and this fact because as shareholders, they are following the evaluation of the diagnostic in order to allow the adoption of some pertinent decisions regarding the sale or the keeping of the actions they dispose. For the big shareholders, the financial diagnostic is founded first of all on indicators expressing the economic growth, the autonomy and the flexibility of the company, and second of all on indicators of profitability. Being in the situation to choose between the interests on short term, they will be attracted by the first option, the only able to bring to the maximization of the value of the company and to assure the survival of this one in the big struggle of the concurrence. The financial diagnostic of the small shareholders which have few information on the activity of the company will be summary and founded principally on the profitability they obtain and on the financial risk they are exposed.

The financial diagnosis of the creditors is based on the analysis of the indicators of evaluation of the capacity of repayment of the debts and of the interests. They seek the establishment of the financial diagnosis on the base of the indicators of risk and insolvability.

The profitability is sometimes associated with the satisfaction registered as a reward of the effort recorded, representing the capacity of one entity to realize the profit, necessary to the development and to the remuneration of the capitals. From this the definition of the profitability given by Cohen E. as a "technical approach of the performance"[2]. In the process of determination of the financial diagnostic, the profitability represents an indicator with a major place. The approach of the profitability is logically integrated in the investigation of the "efficiency" of the activity of a company, through giving the privilege to a monetary evaluation of the performances. This monetary point of view could seem insufficient, because at the first glance, it minimizes the realizations of the company, which have not a monetary expression (the physical capacity of production, the competences of the staff, the social climate, the competitive environment relationships). In fact the systematic approach of the company allows the comprehension of the conversion of every favourable realization

(expressed in quantity and quality terms), in monetary results and this way in profitability.

In this vision, the profitability is the synthetic expression of the results of every nature, one reference indicator in the orientation of the decisions and of the behaviour of the company.

3. The concept of profitability and risk

The concepts of the leading local economists converge to the idea that the "profitability express the capacity of the company to realize a profit necessary to the development and to the remuneration of the capitals"[3].

As the absolute profitability of the company is determined as a consequence of the analysis of the profit it is not enough representative neither for the external users nor for the external users of information, it will be imposed the comparison of the profits mass with other values, which can evidence the methods used to obtain the profit, which can lead to the determination of a series of rates of profitability characterized through a big informational capacity.

The profitability is generally a fundamental constraint of the financial management, together with that referring to the realization of the financial balance of the company. It depends not only on the internal profitability but also on its relationships with the environment, and especially on the attitude of the economic agent to adapt to the variations of the market [4].

The profitability of an entity from the management point of view is a fundamental instrument the decisions regarding the internal management of the economic agent and the relationships with the environment and especially the capacity of the economic agent to adapt to the requirements of the market. In a restrained way, the profitability evidences the measure of the company to realize sales which level which exceed the costs of the activities.

The profitability is expressed by two synthetic indicators: the profit – as an absolute measure of the profitability and the profitability rate, which represents the degree of the capital and the way other resources of the company bring the profit. For these reasons, the rates of return are identified with rates of efficiency.

The profit in the economic activity represents the sense of the existence of this one, a reason of repartition of the opinions regarding the definition of the profit. In the contemporary economic theory, this represents sometimes the advantage resulted in a material form in an action or from an operation or economic activity. In this situation, the economic agents should have relevant information regarding the mass of the profit and its rate for a corresponding orientation of the activity.

But the profit can be regarded as a final element or residual of the difference between the benefits they realized and the related costs, or in other significance, the profit represents an implicit remuneration of the factors of production, and for the maximization of this one can be followed different ways: the organization and the efficacy of the work, through the work volume, time, staff structure; the minimization of the production costs or the realization of quality products through the introduction of the technical progress, which is reflected in the prices.

But the profit can be obtained through ways which are independent from the internal measures of the economic agents, but also through a placement of the economic agent near the trade market, a fact which assure a small level of transport expenses; the situation of the economic agent on the monopole position, a fact which gives to this one the possibility to practice monopole prices; the majority in one unreal way of the profit from an economic conjuncture – inflation, high custom duties reflected in prices.

Just as the profit, the profitability – an economic important category have different conceptual approaches, being regarded as “a synthetic indicator, expressing the capacity of an economic entity to obtain a net profit. There is a very good point of intersection of every other quality indicators”.

The profitability can be defined as the capacity of the company to have a profit or the “profitability can be defined as the capacity of the company to produce a surplus over the level of the expenses”.

4. The rate of economic and financial profitability

The approach of the profitability fits into the investigation of the efficiency of the activity of a company, favouring a monetary evaluation of the performances. This monetary optics could seem insufficient because at the first view it minimizes the realizations of a company, which have not the monetary expression (the physical productivity, the competences of the staff, the social milieu, the reports in the concurrence milieu). In reality, the systemic approach of the company offers the comprehension of the conversion of every favourable realization (expressed in quantity and quality), in monetary results and this way in profitability.

In this vision, the profitability is the synthetic expression of the results of every type, a reference indicator in the orientation of the decisions and the behaviour of the companies.

Included in the battery of the efficiency, the rate of the profitability is determined on the base of the data from the result or balance account, through the report of a result (gross operating surplus, the result of the exploitation, the result of the exercise) at one indicator of effort (costs, turnover, invested capital, equity) [5].

Through the rate of financial profitability will be assured the surprise of the capacity of a company to emit the net profit, through its own capitals engaged in the activity of production, determining the yield of the utilization of the own capitals and taking in evidence the interests of the shareholders with a double aspect: on long term – through the reinvestment of the profit which can assure the growth of the values of the actions and therefore the creation of possibilities of increase of the dividends in the next period, on short term the immediate increase of the dividends.

The increase of the financial profitability can be realized through the growth of the net profit in a superior rhythm – due to the increase of the physical volume of the physical production and of the production of delivered goods, of the reduction of the exploitation, of the fiscal politics of the state or through an advanced growth of the turnover from the growth of the rotation speed of the actives of the company.

It will be justified the affirmation that the rate of the financial profitability interests especially the shareholders – on the base of the value of this rate could be appreciated the measure of the profitability of one investment – being influenced by two categories of factors: the modality of purchasing of the capitals (a reason of sensitivity from the degree of indebtedness of the company and from the financial structure), but also from the modality of determination of the net profit (the calculation of the net profit is influenced by the modalities of calculation of the amortizations and provisions, but also by the way of determination of the deductible and non-deductible expenses on the table of taxable profit).

With the purpose of the delineation of one assembly evaluation on the performances of a company it should be made a reference at the rate of economic profitability which express the efficiency of the economic capital they invested, the efficiency of the material and financial methods given to the activity of exploitation and sale, reflecting the economic results without depending on the way of financing of the capital and on the fiscally politics. The appreciations referring to the efficiency of the constitution of the capital are taking care of the quantity of the monetary surplus which not only has to be enough for the entire coverage of the costs of the used capital, but also to allow the realization of the objective of the financial management of growth of the value of the company. In the choice of the financial structure of the company, the main criterion is represented by the economic profitability.

An economic profitability superior to the rate of debt allows to the company to appeal to debts in order to increase the financial profitability and implicit of the value of the market. At the reverse, an economic profitability inferior to the rate of the debt determines the company to use its own resources and this fact because a supplementary indebtedness leads to the growth of the insolvability risk.

In real terms, it can be said that the rate of the economic profitability should remunerate the capitals invested at the level of the medium rate of yield of the economy and of the economic and financial risk assumed by the providers of capita. The rate of the economic profitability should allow to the

company the renewal and the growth of its actives in a short period of time. Because the rate of the financial profitability is expressed in function of the rate of the economic profitability, we can appreciate that this financial profitability has its origins in the economic profitability, the difference between the two being determined by the politics of financing promoted by the company.

5. The risk

In the market economy, every company is confronted with the risk. The risk equates with the vulnerability of the company. The risks on the domain of the company are found in the form of the risks of exploitation, the financial risks and the risks of bankruptcy.

The risk of exploitation responds to the risk of the realization of a income or estimated result (preliminary), without taking care of the way of financing used in order to obtain this one [6].

In function of the nature of the factors contributing to the generation of some types of risks, the exploitation risks are: the risks determined by the factors of the production process; the risks of management of the factors of the process of production; the risks of the management of the production factors; the risks of extensive and intensive utilization; the risks of the efficiency; the risk of the failures in the information system or in the activity of internal control of the company, the technical risks, the fraud risk, the project risk; the company risk – the result of an action in concordance with some proper characteristics of a company, which are in contradiction with the exigencies of the organization, of the coordination, of control involved in the ongoing of a business with different partners.

The financial risks – the risks generated by the way of financing of the company, taking care of the sensitivity of the net result at the variations of the result of exploitation, they can take the form: the risks of debts; the risks of financing, the risks of liquidity, the risks of audit.

The companies which have a sensitivity to the modifications of the economic and financial variables, it is necessary that in the field of analysis to considerate the

fluctuations of the internal milieu, but also those of the external milieu, in order to discover the effects of the changes, in order to prevent those with unbalanced characteristics. As the activity of the companies is developed under the action of the risk external factors, it is necessary to present those categories of risk: risks of the laws; juridical risks, risks of the natural factors; risks of countries; risks of the market that come from the big variations of prices imposed by the market economy, political risks, risks of image/publicity; risks of inflation or deterioration of the power to buy at a certain moment, risks of counterpart and of credits; the reputational risk.

6. Conclusions

The taking into account of the risks justifies integrally the complex approach of the financial diagnostic of the company. The financial diagnostic, the risk and the solvability of the company contain elements of economic, financial, social or human nature, and the determination of the indicators already mentioned would not be possible but with the help of complete information, actual and relevant contained in the "informational offer of the accountancy" [7].

The actions made in order to establish the financial diagnostic of one entity are not limited to the study of the financial situations, but to the cumulating of these ones with general information in the economic, fiscally and monetary, of juridical and economic nature with those referring to the domain of activity of the entity.

All those information are used for a preliminary investigation of the aspects referring to the functionality of the entity, to a dynamic approach of the results in correlation with the characteristics of the concurrencies milieu, to the evaluation of the degree of risk and profitability.

Human Development ad Poverty Reduction in Nigeria: An Assessment of Millenium Development Goals (1990-2010)

Adediran Olanrewaju Adelowe
Crescent University, Abeokuta, Ogun State, Nigeria
lanre0812@yahoo.com

Abstract

This paper attempted to examine the relation between human development and poverty indicator taken into consideration major millennium development goals parameters in Nigeria. The importance of human development can not be over emphasized as Human Development Report came out in 1990 at a time when development in Africa and the rest of the Third World was in a state of flux as poverty was widespread experience across the countries. This research work was analytical in nature, employed econometric tools for the analysis. The analysis revealed that human development index (HDI) was first regressed on each on the poverty parameters in simple correlation analysis and the statistically significant at 10% and/or 5% level of significance. Also, HDI and some selected poverty related indicators of millennium development goals (MDGs) parameters show a reverse and unexpected relationship but statistically significant all the same using multiple regressions. The Augmented Dickey-Fuller (ADF) unit root test reveals that all the time series variable employed were stationary at levels for both the intercept and deterministic trend. Appropriate policies are therefore recommended on how best to achieve poverty reduction and MDGs. However, human development (HD) is too important to be under-rated in government policies as corruption and mismanagement of economic resources suffered a series of incorrect macroeconomic policies.

Key words: Human Development Index, Poverty, Millennium Development Goals parameters

J.E.L. classification: O15; I32

1. Introduction

Human development plays basic and fundamental role and remain the most important factor in economic growth and development in countries of the world. The

Human Development Index (HDI) is a composite statistic used to rank countries by level of "human development" and separate developed (high development), developing (middle development), and underdeveloped (low development) countries. The statistic is composed from data on life expectancy, education and per-capita GDP (as an indicator of standard of living). The Millennium Development Goals (MDGs) are the world's time- bound and quantified targets for addressing extreme poverty in its many dimensions. They embody the deep aspirations and commitment of the global community for significant improvements in the quality of human life (UNDP 2009).

The only way to reduce poverty in the LDCs without resort to international welfarism or international migration is through the development of productive capacities of the LDCs and the concomitant expansion of productive employment opportunities within them (UNCTAD 2006).

Past researchers in this area have argued that global economic integration should help the poor since the poor countries have a comparative advantage in producing goods that use unskilled labour. In the last two decades, the percentage of the world's population living on less than \$1 a day has been halved, falling from 40 to 20 percentage over the last twenty years. During this period, countries increased their trade share and slashed tariffs

Yet one billion people still live in extreme poverty, and half of the world's populations live on less than \$2 a day. There are two tendencies in analyzing the causes of poverty; one spectrum is microeconomic analyses of the causes of poverty focus on characteristics of the poor (such as illiteracy, living in remote areas, working in subsistence agriculture, etc.) and directing policies to address these in a way that is divorced from the broader macroeconomic context. The macro-context lead to simplistic and misleading assertions that "economic growth is good for the poor." The eradication of widespread absolute poverty and reduction on income inequality is in the content of redistribution of Economic opportunities, which emphasizes the need to provide and guarantee a decent livelihood to majority of the populace; which include the provision of adequate food, shelter and clothing, access to health facilities and education and greater employment opportunities. Lack of these things is both a symptom and causal of absolute poverty and income inequality. (Todaro, 1989)

In Nigeria, the claim of the World Bank was that poverty in the period 1982-1992 was a devastating phenomenon that resulted from a mismanaged economy that suffered a series of incorrect macroeconomic policies. The consequences were evident as expected, visibly evident on the people and made life a groaning experience. The problem was serious enough that in Nigeria the middle class was virtually wiped off as an age old social classification. Development analyst could no more talk about social stratification in hitherto familiar rubrics except to talk about the rich and the poor. As some say the middle class was not wiped off in Nigeria but their classification was, as the situation in the economy could no more effectively guarantee them those goods and services they used to enjoying. For example middle class homes were denied the possession of a car, decent accommodation decent private school for their children, quality meals for the family, health care in the hospital etc. They all disappeared during austerity year after year.

However, failure in the achievement of MDGs and basic cause of poverty is that

there are simply not enough productive employment opportunities in the formal sector for a growing labor force which is the only way to eradicate poverty and hunger - form the bases for the empowerment/enforcement of MDGs of cum a distinctive type of political system in which the rivalries and struggles of powerful and willful person, rather than impersonal institutions, ideologies public offices, or class interests, are fundamental issues.

The paper is therefore interested in answering the following questions: What are the major human development index?; What are the MDGs?; Is there any relationship between HDI and poverty parameters in the MDGs and of what significant?

For the purpose of sufficient evaluation and up-to-date assessment and the remaining part of this research work is divided into four sections.

Section 2 - Literature review is devoted to conceptual clarifications of the terms: Poverty parameters in the Millennium Development Goals, Millennium Development Goals, and Parameters in each Millennium Development Goals, Human Development Report and Human Development Index.

Section 3 discusses the methodology of this work with the test of analysis accompanying the technique of analysis. Follow in discussion also, are the statement of research hypotheses, sources of data, justification for the choice of technique and the decision criteria employed, Section 4 is the presentation of estimated analysis and interpretation of results while Section 5 centers on the summary, recommendation and conclusion.

2. Literature review concept of Human Development

Human Development is a development paradigm that is about much more than the rise or fall of national incomes. It is about creating an environment in which people can develop their full potential and lead productive, creative lives in accord with their needs and interests. People are the real wealth of nations. Development is thus about expanding the choices people have to lead lives that they value. And it is thus

about much more than economic growth, which is only a means —if a very important one —of enlarging people's choices. (Mahbub ul Haq, 1998) Human development is related to economics and standards of living.

Human capital refers to the stock of competences, knowledge and personality attributes embodied in the ability to perform labour so as to produce economic value. It is the attributes gained by a worker through education and experience. Many early economic theories refer to it simply as workforce, one of three factors of production, and consider it to be a fungible resource – homogeneous and easily interchangeable. Other conceptions of labour dispense with these assumptions. Human capital theory predicts that more educated individuals are more productive (and obtain higher earnings). According to the theory, productivity of labour is high with educated individuals and consequently they contribute far more to the level of national income and also earn higher income than their uneducated counterparts. Furthermore, education is a good measure of human development and the relationship between human development and poverty level has a significant effect on economic growth and development in some selected countries of the world.

Human Development Index

Human Development (HD) and Human Development Index (HDI) are powerful concepts, the former the process of empowerment in the possession of the capacity to build up oneself so as to be able to live a long life, be able to read and write and so participate in the societal affairs effectively and above all be gainfully employed to earn a living. The latter merely establishes how far a country has been able to achieve this for its citizens in numerical qualitative evidence represented by a real number. The fact is that earlier indices of development such as per capita income and its various derivatives have not been able to establish this effectively, especially for comparative purposes. HDI is an index fashioned out of education, life expectancy and income in purchasing power parity.

Concept of Poverty

Poverty is multi-dimensional in nature therefore, it defies a unique definition.

There is always difficulty in deciding where to draw the line between the poor and the rich. Aluko (1975) refers to poverty as a lack of command over basic consumption needs, which means that there is inadequate level of consumption giving rise to insufficient foods, clothing and/or other shelter, and moreover the lack of certain capacities such as being able to participate with dignity in society. Poverty is also defined as the inability to attain a minimum standard of living (World Bank Report, 1990).

It is viewed in terms of insufficient income for securing the basic necessities of life such as food, potable water, clothing and shelter. Poverty is more easily recognized than defined. Hence, a universally acceptable definition of the term has remained elusive but from a social perspective, poverty means the denial of choice and opportunities for a tolerable life (UNDP, 1997).

Poverty is a global phenomena which affects continents, nation and people differently. It affects people in various depths and levels at different times and stages of existence; the main difference is the intensity and prevalence of this malaise. Poverty relates to a state whereby individual lacks the ability to cater adequately for his or her basic needs of food, clothing and shelter, variable to meet social and economic obligations, lack gainful employment, skills assets and self esteem and also has limited access to social and economic infrastructures such as health, education, potable water and environment protection (CBN- Economic and Financial Review, 1991).

Human Development Report

The first Human Development Report in 1990 opened with the simply stated premise that has guided all subsequent Reports: "People are the real wealth of a nation." By backing up this assertion with an abundance of empirical data and a new way of thinking about and measuring development, the *Human Development Report* has had a profound impact on development policies around the world.

The 2010 Report continues the tradition of pushing the frontiers of development thinking. For the first time since 1990, the Report looks back rigorously at the past several decades and identifies often surprising trends and patterns with important lessons for the future. These varied pathways to human development show that there is no single formula for sustainable progress in other word no single index could ever completely capture such a complex concept—and that impressive long-term gains can and have been achieved even without consistent economic growth. Looking beyond 2010, this Report surveys critical aspects of human development, from political freedoms and empowerment to sustainability and human security, and outlines a broader agenda for research and policies to respond to these challenges. The HDI is a composite measure of human development covering health and education as well as income, was devised by the late Pakistani economist Mahbub ul Haq for the first Human Development Report in 1990. The new 20th anniversary edition of the Report revisits that original analytical exercise, using new methodologies and international data sources, also looking back to 1970. The HDI 2010 report combines three dimensions: Longevity (a long and healthy life): measured by Life expectancy at birth; Knowledge (access to knowledge): measured by Mean years of schooling and Expected years of schooling and Standard of living (decent standard of living): measured by purchasing power based on GNI per capita (PPP US\$).

Human Development Index (HDI) 2010 ranks Nigeria 142nd position out of 169th listed and under low human development. When look at the HD concept this takes into account all the products of development including education, health etc. Hence, Policy makers and government must be reoriented and tutor to know the enormity of the combination of HDI concept as a guide to development effort to achieve the concept itself and improves.

Poverty parameters in the Millennium development goals

Let us look at the matrix of component as produced by UNDP:

1. The first goal of eradicating extreme poverty and hunger clearly contains parameters of poverty (targets and indicators) important targets include proportion of people earning less than \$2, rate of employment (unemployment), and number of people who suffer from hunger.

2. Achieve universal primary education: Relevant targets include number of pupils completing primary schooling and for the sake of fullness we can include the few indicators (net enrolment in primary school, number of drop outs and literacy rate in the country.

3. Promote gender equality and empower women. Targets include:

Elimination of gender disparity in education in primary and secondary education and in all levels of education and also for the sake of fullness we can include the few indicators of success ratio of boys to girls in primary, secondary and tertiary institutional, share of women in wage employment in non-agriculture sectors and proportion of seats held by women in parliament.

4. Reduce child mortality. The target will include: reduce under-five mortality rate, infant mortality and proportion of under five immunized against measles

5. Improve material health. The targets include: reduce maternal mortality rate and achieve universal access to reproductive health given the indicators.

Maternal mortality rate, proportion of birth attendants by skilled health personnel contraception prevalence rate, adolescent birth rate, antenatal care coverage and unmet need for family planning.

6. Combat HIV/AIDS malaria and other diseases: reverse the spread of HIV/AIDs, universal access to the treatment of HIV/AIDs, reverse the incidence of malaria and other diseases.

7. Ensure environmental sustainability. Target include integration of principle of sustainable development into country policies and programmes, reverse loss of environmental resources, reduce biodiversity loss, reduces proportion of people without

sustainable access to safe drinking water and basic sanitation, improvement in the life of slum dwellers.

8. Develop global partnership for development. Target includes development of an open, rule-based and non-discriminatory trading and financial system, address the special needs of developing countries, including land-locked countries.

An appraisal of these targets and indicators shows that they are mostly if not all based on poverty issues. Although the list is not exhaustive they give us an indication of what to expect if they were to be adequately addressed. They also help to

redress at a glance the frequently misconceived idea that poverty is mainly if not only an income agenda.

An assessment of poverty reduction programmes in Nigeria

Prior to the introduction of MDGs, the Nigeria government especially at the national level introduced a number of programmes and policies to alleviate poverty. The table below summaries a number of such programme between 1986 and 2007.

Table 2.1 Poverty alleviation programmes in Nigeria (1986-Till date)

Programme	Year Est	Target Group	Nature of intervention
Directorate of Food, Road and Rural Infrastructure(DFRRI)	1986	Rural Area	Feeder roads, rural water supply and rural electrification
National Directorate of Employment (NDE)	1986	Unemployment	Training, financing and guidance
Better Life Programme (BLP)	1987	Rural women	Training finance and guidance
Peoples' Bank of Nigeria	1989	Underprivileged in the rural areas	Encouraging saving and credit facilities
Community Banks	1990	Rural resident micro enterprises in rural areas	Credit facilities Banking facilities
Family Support Programme (FSP)	1994	Families in rural areas	Health care delivery, child welfares, youth development etc
Family Economic Advancement Programme (FEAP)	1997	Rural areas	Credit facilities to support the establishment of cottage industries
National Poverty Eradication Programme (NAPEP)	2001	Unemployed youth as well as poor masses	Employ generation in rural sector and societal wealfare.
National Economic Empowerment and Development Strategy (NEEDS)	2004	All citizen that are poor	Human and Economic Empowerment
Millennium Development Goals (MDGs)	2007	Low human development nations. The whole country Nigeria	Human development as a means of nation / national development

Source: Authors Compilation

The Nigeria government's poverty reduction framework is named the National Economic Empowerment and Development Strategy (NEEDS), the state level framework is the State Economic Empowerment and Development Strategy (SEEDS), the local government is the Local Economic Empowerment and Development

Strategy (LEEDS), the community level is the Community Economic Empowerment and Development Strategy (CEEDS), and while at the household level is the Personal Economic Empowerment and Development Strategy (PEEDS). NEEDS has four pillars; empowering people and improving social service delivery;

improving the private sector and focusing on non-oil growth; changing the way government works and improving governance; and value reorientation at all level (World Bank, 2007)

Nigeria has a growing country, moving towards reducing poverty and achieving of the MDGs would translate into significant giant in social and economic development for the whole of sub-Saharan Africa. (World Bank and DFID, 2005:1)

However, Nigeria is blessed with enormous oil wealth, a large and diverse population, sea and river access forests and land. Nonetheless it has not been able to translate these advantages into sustainable peaceful development. This is largely the result of poor governance and weak state institutions, deeply embedded in the socio-political nature of society. Whether the national, state, local, community and personal development strategies could contribute to achievement of the MDGs will depend on proper implementation of these goals as well as underlying cause of poverty of poverty- discrimination, corruption, patronage politics and the likes are tackled.

3. Theoretical Framework

The theoretical framework for this study is rooted in the new growth (endogenous growth theory which suggests that a higher long run rate of growth of output and improvement in social welfare can result from greater openness and actualization of millennium development goals, sustainable development among other macroeconomic goals.

Endogenous growth theory simply means economic growth from within a system; usually a nation state. The theory offers hope to newly industrializing countries (NICs) an alternative way to develop without becoming dependent on trade only. While traditional theories of growth focus on trade as the engine of growth; endogenous growth theory focuses on education, on-the-job training and development of new technologies for the world market. By implications poor country can only grow and develop by acquiring the substances of endogenous growth theory (education, training and technological

development) not be closing the doors to the global market but by employing strategies that will enhance their benefits from economic openness. Economic growth is driven by accumulation of knowledge (endowed with, or imported) and that endogenous growth does not just happen; it has four basic input- capital (measured in units of consumption of food); labour (skilled available from a healthy human body), human capital (activities such as formal education and the job training) and an index of the level of technology. The key in Roman's model is an adequate stock of human capital and deduced that growth is integration into an economy with a large amount of human capital and not just large number of people. (Romer, David 1996)

4. Methodology

The research design is analytical in nature. This study employed ordinary least square (OLS) in analyzing the relation as well as significant effect of human development and poverty reduction through MDGs selected parameters in Nigeria between 1990 and 2010. The data for the study are sourced from Human Development Report (HDR) 2010 and various issues, National Planning Commission (NPC) publications, United Information Service (UIS) 2010, Human Development Report Official (HDRO) own calculation, United Nation Children's Fund - UNICEF JMP official MDG Report, National Bureau of Statistic (NBS), Central Bank of Nigeria (CBN) statistical bulletin of various issues. **Research Hypothesis**

The hypothesis formulated for this research work is hereby stated in this section.

H01: There is no relationship between human development and poverty reduction in Nigeria.

H02: Human development does not have a significant effect on poverty parameters in the millennium development goals in Nigeria.

Estimation Techniques

In order to ensure the stability and robustness of the regression models, a series of diagnostic tests such as

estimated coefficient, t-statistics, significant level, Durbin Watson technique were employed as presented in the regression results. For stationarity test using unit root in the time series Augmented Dickey-Fuller test were also employed to confirm the suitability of the data and we were satisfied with the quality of the data.

Model Specification

The national income accounting framework in an open economy expresses aggregate

demand – AD as;

$AD = Y_d = C + I + G + (X - M)$ Where: $Y_d =$ Aggregate demand

C = Consumption expenditure

I = Investment expenditure

G = Government expenditure

X = Export value

M = Import value

$AS = Y^s = C + S + T$

Aggregate supply equals the sum of goods and services produced in the economy; it is the total output produced in an economy from the above equation where;

$Y^s =$ Aggregate supply

C = Consumption expenditure

S = Saving

T = Taxes

In Keynesian macroeconomic theory, the equilibrium level of output and employment is determined jointly by AD and AS.

Thus, $C + S + T = C + I + G + (X - M)$

For the purpose of this study, the equation is defined and re-specified based on Keynesian school of thought as multiple regression analysis is used to estimate relation between human development index (endogenous variable) and poverty parameters (exogenous variables) in the MDGs in Nigeria.

The model are specified as

Model 1

$Y = 0 + 1X_1 \dots X_{17}$

Where,

Y = HDI – Human Development Index

X₁ = POV – Proportion of population living below \$US1 per day

X₂ = NETP – Net Enrolment in Primary Education

X₃ = GBERP – Ratio of girls to boys in Primary, Secondary and Tertiary

X₄ = UFMR – Under Five mortality rate

X₅ = MMR – Maternal Mortality Ratio

X₆ = HIV – HIV Prevalence among population aged 15 – 24 years

X₇ = LACF – Land Area Covered by Forest

X₈ = WNP – Women in Parliament

X₉ = SANIT – Sanitation

X₁₀ = DEF – Deforestation

X₁₁ = IFMR – Infant mortality rate

X₁₂ = GDPPPP – GDP Purchasing

Power Parity

X₁₃ = INCI – Income Index

X₁₄ = LITR – Literacy

X₁₅ = GNIPC – GNI per capita

X₁₆ = GGDP – Growth rate of GDP

X₁₇ = ODA – Official Development

Assistance

All these variables are considered on HDI as a simple regression model. Model 2

The second model is multiple regressions.

$Y = 0 + 1X_1 + 2X_2 + 3X_3 + 4X_4 + 5X_5 + 6X_6 + 7X_7 + U_t$

Where,

Y = HDI – Human Development Index

X₁ = POV – Proportion of population living below \$US1 per day

X₂ = NETP – Net Enrolment in

Primary Education

X₃ = GBERP – Ratio of girls to boys in Primary, Secondary and Tertiary

X₄ = UFMR – Under Five mortality rate

X₅ = MMR – Maternal Mortality Ratio

X₆ = HIV – HIV Prevalence among population aged 15 – 24 years

X₇ = LACF – Land Area Covered by Forest

Aprior Expectation

The apriori expectation of the multiple regression models require that, HDI will have positive relationship with proportion of population living below \$US1 per day and negative relationship with other parameters.

From the apriori expectation, following economic theories and conventions, it is expected that a relationship exist between HDI and the MDGs parameters. Western donors continue to stay engaged in the country because of the persistent increase in the rate of poverty ratio. As it is obvious that, HDI could contribute to achievement of the MDGs will depend on proper

implementation of these goals as well as underlying cause of poverty of poverty-discrimination, corruption, patronage politics and the likes are tackled.

5. Empirical Analysis

Interpretation of the estimation results

Considering the simple linear regression for the first model specified, we expect that the Human Development Index (HDI) will involve a change that is mirrored by the changes in the MDG indicators on offer. As the proportion of the population with US \$2 per day grows, so does HDI as should be expected and the relationship is statistically significant just as the net enrolment (NEP) in primary education, girl/boy enrolment ratio in primary education (GBERP) women in parliament, GDP (at US Purchasing Power Parity), growth of GDP (GGDP). True one can argue that HDI is only a statistical calculation of HDI but it is equally true that there is an underlying relationship of true human development identified that must be encouraged by policy and practice. Some of the poverty related indicators of MDGs behave in this way but not only as a statistical package and it is important therefore to elicit the attention of government. The current group includes gross national income per capita (GNIPC), and adult HIV prevalence rate. As this decreases HDI increases with the income index (INCI). Should the two income indicators be in this category for examination? Some argue but this only supports the contingency thesis of Anand and Sen (1994) that unless the public expenditure role of these variables are targeted they end up being an inferior indicator of human development. This is re-examined in this study. Some of the MDGs indicators - exhibit outright insignificance, and unless allowance is given to a low probability of significance as we did they would not have been included. This also includes official development assistance (ODA) in particular. This is not surprising as ODA has never played a significant role in Nigeria's overall development.

This takes us to the areas where HDI and poverty related indicators of MDGs show a reverse and unexpected relationship but statistically significant all the same. We have for instance included under five mortality rate (UFMR) and land area covered by forest (LACF). The former is understandable, but the later does not

immediately appeal to common reason when we argue that as land area covered by forest increases access to crop cultivation declines, an argument located outside sustainability. Where the forest constitutes a hindrance to agriculture, particularly in clearing which can be very expensive from all practical experience. This will make crop coverage to reduce, leading to lower HDI. This obviously gives support to any public policy that assists farmers with farm clearing subsidy. We can also look at relationships between HDI and poverty related parameters in MDGs that are positive and statistically insignificant. This includes, HIV a situation that calls for careful interpretation. As estimated adult prevalence rates decrease, the economic activities of the adult population will increase and this automatically lowers hunger and increases opulence, to use the language of Mum (Anand S. and A. K, Sen, 1994 : 4); hence the increasing nature of HDI in this case. This is one of many reasons why HIV is dangerous and must be fought by government policy and more action taken to bring its spread under control with a view to totally eradicating it though the achievement of the relevant MDGs. Sanitation has positive relationship with HDI but it does not received sufficient attention to be effective and it unable to push the HDI upwards. Deforestation has negative correlation with HDI, and deforestation in fact opens up the land for farming as many people from such areas will testify and it therefore increases access of farmers to more farm area. More bountiful harvest resulting from this reduces hunger and increases human development, consequently HDI via poverty reduction. This is statistically significant because in the south where the issue is often raised, the extent frankly is yet to be a painful one. We also note that deforestation is not the same thing as desertification.

Government attention will seem to be that of reducing poverty and regulating the other, i.e. enrolment in primary school. True Earlier we found that as separate issues government will want to give significant attention to both but less to net enrolment in primary school. With the two in a contest of attention, government will treat net enrolment with a non-significant

attention. Again poverty receives the attention as in contest for attention between poverty and maternal mortality rate. Significantly, looking back at the results for each of maternal mortality rate and under five mortality rate, the former had been significant and the latter not at all, which means that in a policy contest with the poverty indicator attention to maternal mortality rate has been a loser.

From the second model of multiple linear regressions analysis was equally employed to capture the effect of poverty and some selected MDGs on human development index in Nigeria for the period 1990 to 2010. The regression equation shows that there is negative relationship between endogenous variable and exogenous variables except for the intercept. The probability shows that infrastructural facilities provision was not adequate and proper policies measure to achieve MDGs are lacking as government focus politics, combating corruptions, reducing crime rate and militancy in Niger-Delta cum religion and ethnic fight in the northern part of the Nigeria as he struggle to gain international recognitions to free from terrorist listed countries. The adjusted coefficient of determination (R^2) shows a fit with 30.9 percent of human development index explained by the variables in the equation. In this study we have been selective in the choice of poverty parameter in relation to MDGs, carefully choosing those for which data are readily available and for which government can be challenged to act. The results have shown that government has not achieved any of the MGDs and he doesn't seem to be serious about work out proper way for the reality and achievement of the goals. The reason for this is that little influence of the explanatory variables can not have meaningful effect on human development index, reduce poverty and cause development in Nigeria.

However, Durbin Watson (D.W) statistics of 1.93 shows it is significant as the value is below the bench mark of 2.00, we can conclude that there is no auto correlation or serial correlation in the model specification hence, the linear assumption is

not violated.

The unit root test result reveals the stationary at level for both intercept and deterministic trend of all time series variable on HDI.

In level, HDI is stationary at 1%, 5%, 10%, for intercept and at 1%, 5% level for trend. And HDI was found to reject the null hypothesis of no-stationary at level but strong and high degree of responsiveness of HDI and the poverty parameters in the MDGs at second difference Therefore, all the series are taken to be stationary at level for unit root models with intercept and trend.

6. Conclusions

The conclusions of this study are fairly straight forward.

Data availability has not been a problem but it requires hard work to accomplish by locating them in statistics publications, reports produced by international development agencies and the web site of particular agencies. Sufficient time to accomplish this task is of the essence.

A study such as this also requires personal interviews with government planning and development agencies. For example it will be interesting to know how and why they come about the development policies of government and some decisions of government are taken.

On the substantive issues of the relationship of HDI you the poverty parameters of the MDGs following should be noted:

In the main, government and the people (individuals and agencies) taken the decisions that give rise to what we have, but government policies are critical;

So the data we have as evidence are a product of , in the main, the decisions and policies of government; and it follows that the results of technically produced relationships come about in a large part as evidence of what has been taking place, and so without doubt

The results must be interpreted as much; consequently the issues within MDGs and the parameters of poverty come alive from government policies and decisions, as we combine variables for estimation, and as if

government is taking to us the following parameters of poverty came out as those that have greatest influence on HDI: poverty as measured by those who earn less than US\$1.00 or US\$2.00 per day, land are covered by forest, women in parliament, growth rate of GDP, gross national income (PPP) per capita, income index, net enrolment in primary education, ratio of girls to boys enrolment in primary school, under five mortality rate, HIV as adult prevalence rate, maternal mortality rate, sanitation in that order of importance; the significance of these variable when HDI is regressed on them singly is encouraging some and not for a few orders, the key ones are 7 or 8 in term of explaining the variation of HDI, the producer of trying single variables first and multiple regressions with some selected variable later produced a good result at glance. However, we must not see this as explaining a large shunk of the variation of HDI. In most cases 60-70% of the variation has been left unexplained, this means that further studies need to be done to unearth the missing links;

Significantly, the income variables are middle performance in terms of relationship with HDI, by and large the socio economic variables (poverty, land area covered by forest, women in parliament, girl boy enrolment ratio in primary education are still the issues that more influence HDI.

Unfortunately such decisions often go to support the wrong issues because we must ask the question why maternal mortality falls behind in policies and actions or why net enrolment in primary school or even adult literacy etc lack sufficient concern and support, we can multiply the list;

Recommendation

HDI is too important to be under-rated in government policies and consensus must be sought to bring the development system to reason together on it;

We could not have tackle all variables that are poverty parameters in MDGs; they are many and only some important ones were tackle because time is of the

essence as we search out the necessary data.

Multiple variable indices provide a better guide to development policies and decisions;

Government will need to convince itself that single issue parameters like GDP and its derivatives as a basis for decision making will lead a nation nowhere as evidence continue to show; so it actions need to prioritized;

Government cannot just look at HDI yearly and endorse it, it must do so with concern, asking itself and the agencies how it can do better; and lastly

Government should put all effort and seriousness in crossing the line to middle level country HDI and achieve MDGs and vision 2020.

The Semantic Dynamics of the Intellectual Capital Concept

Agoston Simona

Puia Ramona

Academy of Economic Studies, Bucharest

simona.agoston@ase.ro

ramonapuia@gmail.com

Abstract

Despite the fact that the concept of intellectual capital gained importance in the last decades among both academic researchers and practitioners and it is considered one of the most important sources of competitive advantage in the „new economy”, a semantic convergence of the concept has not been reached yet. The present paper aims at analysing the semantic development of the concept and presenting the main approaches of intellectual capital from a chronological perspective.

Key words: capital, intellectual capital, semantic dynamics, intangible assets

J.E.L. classification: D24, J24

1. Introduction

The transition to the knowledge economy exerted a great impact on organizations' management structures and approaches. The knowledge economy requires a new approach of managerial theories, that implies intensive use of knowledge, which becomes simultaneously main resource, product of economic activities and source of sustainable competitive advantage. In the new economy, the ideas, which are basically embedded in knowledge, are of paramount importance, their generation and development represent a priority for organizations, they manifest themselves as ineffable and substantial, essential and concrete, functional and conceptual in the same time [1].

In developed countries, since 2006, more than 50% of GDP comes from knowledge-based industries (e.g.: software, pharmaceuticals, communication technologies, education etc). In the U.S. over 80% of GDP comes from these industries and

in the manufacturing industries, activities based on intellectual work such as research & development, design, technological innovation produce the highest added value [2].

In the foreground of the managerial theories of the 20th century were situated the three classical factors of production: land, labor and capital. Considering this classic approach, the term "capital" refers to physical and financial capital, which represents a form of material wealth, consisting in goods, buildings, machinery or financial resources used to produce new goods and services. The concept of intellectual capital emerged in the scientific literature as a natural organizational reaction aimed at drawing the attention on the existence of another form of capital, considerably different from the well-established one [3].

Due to the fact that the term "capital" describes a strong concept, it has been used beyond its initial semantic field. The semantic extension of a strong concept can be eventually more difficult and challenging to achieve and delimitate than the creation of a new concept [4]. We consider that the aforementioned statement can be also applied to the concept of "intellectual capital", which has undergone different approaches and has being defined from different perspectives, without reaching a unanimously accepted conclusion. Despite the large number of researches conducted in this field, the conceptual boundaries of intellectual capital are difficult to establish and it still represents a fuzzy concept. In the next part, we will try to analyze the concept of intellectual capital from the perspective of its historical development.

2. Emergence and development of the concept „intellectual capital”

Isaic-Maniu (2010) argues that, about 30 years ago, the American economist John Kenneth Gallbraith used for the first time the term “intellectual capital”. From the very beginning, Gallbraith emphasized the dynamic dimension of intellectual capital, suggesting that it means more than knowledge or intellectual skills, it means action.

Sullivan (2000) refers to the work of the Japanese Itami, who in 1980 published a book named "Mobilizing invisible assets". Thomas Steward was the first one who used the term “intellectual capital” in a press article, called Brainpower, published in 1991 in Fortune Magazine. In the same year the Swedish company Skandia appointed Leif Edvinsson as the world’s first Director of Intellectual Capital. Four years later Skandia released the first Report on Intellectual Capital [7]. The pioneer countries regarding the initiatives of applying in business the concepts from the field of intellectual capital, its valorization and evaluation are the Nordic countries [8]. In 1997 there were published three major books about intellectual capital: one published in New York, "Intellectual Capital: realizing your company’s true value by finding its hidden brainpower" by Edvinsson and Malone and other two in London: „Intellectual Capital. Managing in the New Business Landscape” by Roos et al. and “Intellectual Capital- The New Wealth of Organizations” by Stewart. These works represent milestones in the area of intellectual capital and they basically transformed this research sector into an autonomous study and research field.

In the following years several initiatives meant to promote the theory behind intellectual capital were launched. Therefore various journals dedicated to the study of intellectual capital were established and several conferences on this topic were organized. The number of the scientific articles indexed in Emerald database which focus on intellectual capital grew from 133 in 2000 up to 324 in 2005 [9].

The number of private companies which offer consultancy in the field of intellectual capital increased also significantly over the last years. Among the most prestigious ones,

one can mention „Intellectual Capital Service” led by Göran Roos and „KPMG’ Knowledge Advisory Services Group” led by Daniel Andriessen.

The following table provides an overview of the main contribution in the field of intellectual capital.

Table 1. Main contributions in the field of Intellectual Capital

Period	Contribution
Beginning of the '80s	General ideas about intangible assets
Middle '80s	Emerges the concept of “Information society”, forerunner of the “New Economy” and the difference between book value and market value increases significantly in the case of many companies
End of the '80s	The first concerns regarding intellectual capital coming from accountancy sector and the first attempts of finding new ways of evaluating a company value
Beginning of the '90s	Systematic initiatives for the evaluation and external reporting of intellectual capital (Leif Edvinsson director of intellectual capital within Skandia- the abstract concept embodies now corporate significance).
Middle '90s	Nonaka and Takeuchi publish „The knowledge creating company” in 1995- it is drawn the distinction between intellectual capital and knowledge, the link between knowledge management and intellectual capital is set. The electronic simulation Tango is created in order to educate the managers with respect to the management of intellectual capital Milestone books are published

Period	Contribution
	The Skandia model of reporting intellectual capital is adopted by further companies
End of the '90s	Intellectual capital becomes a popular topic approached within several conferences; there are established the first academic journals whose main topic is intellectual capital; There are launched ample projects in this research field and the first country reports on intellectual capital are issued (especially in the Nordic countries)
Beginning of the 2000	Kaplan and Norton (2004) put forward in their book "Strategic map" an integrative perspective over an organisation's strategy, which includes the valuation of intellectual capital; In 2004 Andriessen publishes his book "Making sense of Intellectual Capital", which represents an exhaustive analysis on intellectual capital;
Middle and late 2000	The importance of Intellectual Capital is widely acknowledged within academia and among practitioners; The number of empirical studies concerning Intellectual Capital records a quantum leap; By researching and developing new methods of transforming potential intellectual capital in operational capital which brings added value to an organization, it is placed more emphasis on the dynamic dimension of intellectual capital, rather than on the static one.

Source: Adapted after Garcia-Parra et al. (2006) and personal amendments

3. Semantic dynamics

The word „capital” originates from Latin, from the substantive „caput” which means leader. Afterwards the word was used in the financial sectors, representing the principal of a debt. Over the years, its meaning crossed financial boundaries and it represented an

amount of money which could generate profit for its holder or other types of wealth (Böhm-Bawerk in [7]).

Over time one can remark many attempts of defining intellectual capital. Their large number and content variety suggests how difficult it is to define and delimitate a concept very “intangible” such as intellectual capital. One can identify three main approaches which lead to a holistic picture over the concept of intellectual capital: the accounting approach, the metric (econometric) one and the approach coming from the perspective of strategic management [3], [5].

The accounting approach of intellectual capital is a result of the incapacity of the current accounting systems to offer accurate information on the real value of an organization. There were recorded relevant differences between the market value of an organization and its net book value. This challenge was initially noticed by Lev-Accounting and Finance Professor at Stern School of Business from New York, Sveiby-Professor of Knowledge Management at Hanken Business School from Helsinki, Finland, Stewart, Van den Berg, Sullivan and other pioneers. The promoters of this approach use mainly the term intangible assets.

The international accounting standards define intangible assets as non-monetary assets without physical substance which are used in the process of producing or supplying goods and services, rented to third parties or used for administrative purposes. Therefore, in order to be considered an intangible asset, a certain item has to be identifiable, an organization has to be able to control this item and it has to be able to generate further economic benefits [10]. Unfortunately many intangible assets do not fulfill the above mentioned conditions. Just to mention some examples: reputation, important key employees which possess tacit knowledge etc. If the above criteria are not fulfilled, they are considered an expense and therefore harm the accuracy of balance sheet [7]. However, even specialists who argue the inadequacy of traditional accounting systems are skeptical regarding the introduction in the annual accounting reports of non-financial factors which are very subjective and difficult to quantify. The

inclusion of intangible assets in the accounting reporting represents a very complicated issue, also due to the fact that it interferes with one of the basic accounting principles, namely, the independence of the exercise. This principle implies the clear delimitation of revenues and expenses corresponding to the reporting period, irrespective of the moment when the amount is cashed or the payment is made [11]. Steward (1999) argues that despite all these challenges, non-disclosure of intangible assets in the balance sheet would mislead in respect of the real value of an organization.

The second approach, the metric one, focuses on finding patterns and models for the assessment of intellectual capital. Some of the most important models are: Market to book value, Tobin's Q Ratio, Balanced Scorecard, Skandia's Intellectual Capital Navigator, Intellectual Capital Indicator, Sveiby's Intangible Asset Monitor, Business Excellence Model etc. The underlying principle of all these models consists in the integration of other assessment indicators than the financial ones, which can offer just partial information on an organization. The main goal of the models consists in providing a holistic picture of the company to its stakeholders.

The third approach, which considers mainly the strategic management perspective, refers to the paradigm shift regarding the sources of competitive advantage. Therefore, the theory developed by Porter, according to which, in order to gain competitive advantage a company should focus on the external environment, was amended by the resource based theory according to which companies should focus on the analysis and exploitation of strategic internal resources and lately by the theory in which the analysis of intangible assets prevails [13].

In the scientific literature, depending on the initial research field of the authors, one can encounter the terms "intellectual capital" mainly in the management area, "intangible assets" or "intellectual assets" in accounting, "knowledge assets" in macroeconomy. In most of the cases all the aforementioned terms denominate the same underlying concept, unless the authors make a specific statement in this respect.

Many authors tried to define the concept of intellectual capital (see Table 2), but despite all these attempts a definition which can be easily operationalized has not been found. Steward (1999) defines intellectual capital as intellectual materials- knowledge, information, intellectual propriety, experience, which can be used in order to create wealth. In the same direction are situated also Edvinsson's and Malone's (1997) and Sullivan's (2000) approaches: knowledge that can be converted into value. According to Roos and Roos's (1997) intellectual capital is the sum of a company's hidden assets that are not included in the accounting reports and represent the most valuable source of competitive advantage. Caddy (2000) defines intellectual capital as the difference between intangible assets and liabilities. Roos et al. (2005) argues that intellectual capital contains all the non-monetary and non- physical resources which are partially or totally controlled by the organization and contribute to the process of added value creation. Peng et al. (2008) states that intellectual capital represents the critical resources used by companies in order to perform production activity and generate added value. As one can remark, all these definitions are quite vague and metaphorical. Bratianu (2006) tries to capture a more pragmatic view over intellectual capital, by defining it as an organizational potential, consisting of different types of knowledge, which, under the influence of technological and managerial processes, has the capacity to convert into a set of operational and active elements, which bring added value and are embedded both in the material and immaterial final products and services offered by a company. It is of great importance Bratianu's remark regarding the necessity to transform the potential intellectual capital into operational capital, as a sine qua non condition in order to obtain economic wealth.

Table 2. Definitions of intellectual capital

4. Conclusions

Once great differences between the market value and net book value of a company were seized, an increasing importance was given to the concept of intellectual capital. The conceptual development occurred from three different directions: accounting, econometrics (assessment of intellectual capital) and strategic management. Due to the different original field of research several terms are used in order to denominate intellectual capital: intangible assets, intellectual assets, knowledge assets etc. In most of the cases, unless the author makes a special remark in this respect, these terms have a interchangeable name, illustrating the same concept.

Despite the fact that many authors tried to define intellectual capital, the scientific community did not reach a consensus in this respect. This is on one side due to its high complexity and abstract features and on the other side due to the embryonic stage of this scientific field.

Some Aspects Regarding the Relationship between the Exchange Rate and the Interest Rate

Aivaz Kamer Ainur

„Ovidius” University of Constanta, Faculty of Economic Sciences

kamer_aivaz@yahoo.com

Abstract

The literature about the relationship between the exchange rate and the interest rate is quite extensive. This paper realizes an overview of the theories, problems and limits regarding the exchange rate and one of its determinant, the interest rate.

Key words: exchange rate, interest rate

J.E.L classification: E00

1. Literature review

One approach is the one about the determinants of the currency exchange rate, which extends the quantity theory of money for open economies. Under this approach, the national and the international money market are linked by the purchasing power parity, resulting in an equation that can determine the exchange rate and the interest rate plays a major role. In the case of the perfect price flexibility, changes in the nominal interest rate are fully reflected in the expected level of inflation, and in this manner a bond between the exchange rate and expected inflation differential can be achieved.

The next significant moment in the evolution of the models which theorizes the connection between the two macroeconomic variables is the development of the Mundell-Fleming model, which was accomplished in 1976 by Dornbusch and which points out that the rigidity of the prices might lead to an overvaluation of the exchange rate. This model was very appreciated by other researchers, and even by the monetary policy makers due to the fact that it corresponded to the realities after the fall of the monetary system from Bretton Woods. The model realized by Dornbusch identifies a negative relationship between the real exchange rate

and the real interest rate differential. The studies made for the testing of this model did not demonstrate the real existence of this connection or if it exists, the statistic signification is very low.

Most of the empirical works that test the reliability of the model proposed by Dornbusch use two-step cointegration methods by Engle-Granger. Messe and Rogoff (1998) use monthly data for the exchange rates USD / DEM, USD/JPY and USD/GBP during February 1974 and December 1986 in the purpose of testing the relationship and they discover that there is no strong bond between the interest differential rate and the real exchange rate, no matter if they are for short term or long term, these conclusions being contradictory with those of the monetary models.

Edison and Pauls (1993) use cointegration and the model of the error correction for highlighting the connection between the real exchange rate and the real interest differential. Using quarterly data for the 1974-1990 period for the USD currency to a weighted basket with the volume of the commerce, which is composed with the change from the G-10 and for the interest rate related to the treasury bills emitted by the United States and to the weighted interest rate for the states titles of the G-10 countries, the two authors prove the inexistence of a systematic relation between the two variables.

The results obtained by Meese and Rogoff (1998) and Edison and Pauls (1993) cannot deny the null hypothesis of the lack of the cointegration equation. Somewhat more favorable results are obtained in the case in which the method of Johansen is used as a method of testing the cointegration relation. Using the cointegration method for a data panel, MacDonald (1997) is the one who certifies the existence of the relationship

between the exchange rate and the interest rate.

Many studies regarding the empirical models dealing with the "disconnection" of the exchange rate from its determinants were written. Obstfeld and Rogoff (2000) show that the bond between the exchange rate and the monetary policy is very important, but this correlation cannot be absolutely necessarily interpreted as a direct bilateral correlation. Other variables, as the permanent threat of the speculative attacks in the case of emerging economies, can determine a common fluctuation of the exchange rate and of the interest rate, fact that does not happen in the case of the emerging economies. In the case of Romania the interest rate does not integrate itself in the cointegrating vector of the determinants of the exchange rate.

Likewise, there are many studies which focus on the relation and on the volatility of the two macroeconomic variables. Reinhart and Reinhart (2001) show that a bond between lower volatility of the exchange rate of the G3 countries and the interest rate volatility and on the other hand of the consumption must be accomplished. Most of the countries can reduce the volatility of their exchange rate by changing the short term interest, as a reaction to the international changes of the exchange rate. These measures determine the increase of the interest rate volatility and of the costs of the G3 countries, which is going to influence the emergent countries that are net debtor countries to these.

Using the same methodology as Reinhart and Reinhart (2001) and using a data panel for 39 countries and monthly data for the January 1970 – April 1999 period, Calvo and Reinhart (2002) analyze the existent volatility between the G3 countries and the emergent economies. The conclusion of the authors is that this lack of credibility of the monetary authorities, correlated with the fear of letting the national currency fluctuate freely, has as an effect a decreased volatility of the exchange rate, which is associated with a high volatility of the interest rate. The low volatility of the national currency is not a result of the lack of the external shocks, but a result of using all the monetary policy instruments in order to mitigate the impact of these shocks in the level of the exchange rate. The interest rate policy in the emergent economies replaces the unsuccessful

interventions of the foreign currency reserves. This conclusion is valid regardless if the exchange regime is a fixed one or if it is related to other currency, fact that determines the two authors to advise the monetary authorities to give up fixing the exchange rate.

The conclusions for the emergent economies are not valid for the developed countries. Flood and Rose (1996) point out that the OCED countries do not necessarily have to choose between the volatility of the exchange rate and the macroeconomic stability, while maintaining the stability of the interest rates and of the money supply.

2. Theoretical models regarding the relationship between the exchange rate and the interest

The assumption that the interest rate and the exchange rate are closely related dates back to the end of the 19th century when it was phrased by Lotz, but it began to gain magnitude after World War I, when the futures market started to develop. Two theories were formulated regarding the interest parity: one covered and one uncovered.

In 1923, Keynes tried to develop a theory related to the behavior of the term exchange rate, identifying the reasons why the spot rate and the term exchange rate and why the investors prefer to hold funds in a financial center and in a certain currency.

Keynes's argument can be summarized as follows: we consider r_t and r_t^* the interest rates that can be gained between the t and $t+1$ moments in the national currency, between the countries A and B. S_1 and F_1 are the spot rate and the term rate between the currency of the two countries.

They are expressed as monetary units from the A currency for a unity from the B currency, and s_1 and f_1 are their logarithms. A currency unit from the B currency, transformed at the spot rate in the A currency and invested on the A market becomes $S_t(1+r)$ monetary units from the A currency in the $t+1$ moment. Likewise, in the case of a forward contract ended in the t moment, the initial monetary unit from B can be invested until the $t+1$ moment and afterwards it can be transformed in $F_t(1+r_1^*)$ monetary units from the A currency. As both

probabilities of investing are considered equivalent due to the lack of arbitrage, we are going to have:

$$S_t(1+r_t) = F_t(1+r_t) \quad [1]$$

$$\frac{F_t - 1 + (r_t + r_t^*)}{S_t} \approx 1 + r_t - r_t^* \quad [2]$$

$$\frac{F_t - S_t}{S_t} \frac{1 + (r_t + r_t^*)}{1 + r_t^*} \approx f_t - s_t \approx r_t - r_t^* \quad [3]$$

The first relation, or the third form, the one which is approximated, represents the covered parity condition (CPC) of the interest rates and determines the bonus or term discount that the investors have to pay to cover the exchange rate risk associated to a contract through which they have to give or to receive a sum in the foreign currency in the moment $t+1$.

The derivations from CPC are based on the comparison of the two alternatives of investing the B currency in the t moment to obtain a sum in the A currency in the $t+1$ moment. A third alternative exists on the market, which places the monetary unit from the B currency and transforms the sum obtained in the A currency at the existing exchange rate on the market maturity, resulting $S_{t+1}(1+r_t^*)$ monetary units from the A currency.

In the case of using this alternative, the investor is going to have an uncertainty regarding the evolution of the exchange rate in the $t+1$ moment. When the currency conversion will be realized, the currency risk will not be covered in this case.

This new hypothesis represents the hypothesis of the uncovered parity of the interest rate (UIP) and it shows that the powers of the market tend to balance the profits which the investors expect to gain in both covered and uncovered alternatives.

From the monetary policy point of view, the importance of the validity of the UIP derives from the wish of determining the effect of the investments of the authorities on the foreign exchange markets in order to influence the exchange rate with purchases and sales of currency. If the UIP is verified, and if the interest rate does not change, the interventions on the currency market do not have as an effect the change of the spot currency to the forward currency, which

means that the monetary authorities do not have, in this case, two different instruments: the exchange rate and the interest rate.

The sterilization on the currency market can be accomplished though, and if the UIP verifies, due to the fact that the interventions represent a signal regarding the future intentions of the monetary authorities to adjust the interest rate so that the foreign exchange targets to be realized.

The UIP hypothesis requires the expected value of the future exchange rate to be known, which is quite relative.

3. Conclusions

In the evaluation of the benefits of using the interest rate for determining the changes which will appear in the level of the exchange rate or in the forward rate for determining the future spot rate, the dimension of the errors produced in the estimations must be evaluated. The interest rate differential explains only a small proportion of modifications which occurred at the exchange rate level and the proportion between the expected changes and the unexpected changes is favorable to the latter ones.

A plausible explanation for the fact that the interest rate differential explains only a small percentage of the evolution of exchange rate and for the fact that, in general, changes in the direction of the course are falsely predicted, is that the changes in the exchange rate are caused by unexpected information as the monetary politics announcements or as the publishing of economic statistics data.

Another explanation can be given by the efficiency of the currency market. The assumptions behind the definition of market efficiency state that the investors are risk-neutral, they are rationally making their expectations, and the set of information that are needed in making the expectations is available for all the market participants.

A solution for the correct estimation of the future evolution of the exchange rate is abandoning the UIP hypothesis and estimating the exchange rate using the portfolio theory, a case in which we have to introduce the risk bonus for introducing the unexpected fluctuations in the model.

Another possible explanation for the estimation errors is related to the time needed for achieving the analysis: the expectations can need a longer time than the analysis to be achieved. If the expectations are rational and if they predict an appreciation or depreciation in the future for the currency, these expectations will be included in the forward rate.

If the analysis period is not long enough, the depreciation might be realized only out of the expected time, which makes within the interval of the forward rate error estimator to be a spot rate. Another possible explanation is related to the lack of a complete information set, the market participants are creating their expectations depending on what they think that it going to happen on a monetary politic level.

On the other hand, the monetary authorities use the interest rate as an instrument on the monetary politic market, including when they are working on influencing the exchange rate, which determines the occurrence of the estimation errors.

The Effects of the Environmentally Caused Issues on the Global Economy

Aivaz Kamer Ainur

Reşit İren

„Ovidius” University of Constanta, Faculty of Economic Sciences

kamer_aivaz@yahoo.com
irenmorgenstern@yahoo.com

Abstract

Changes in the environment alone will not result in conflict. They need to be combined with existing divisions within society, be they ethnic, nationalist or religious.

Any change in the environment may affect the global economy, even if the environmentally caused conflicts might not be so clear in the beginning.

The relation between climate and environmental changes and economy is very close.

The environment influences people all over the world in numerous ways.

It is not incorrect to state that the environment influences all the activities of the humans in every single way, not only directly, but also indirectly.

The changes in the environment are irreversible and they cause a multitude of reactions, as they have a severe impact on all our activities.

Key words: environment, global economy, climate change.

J.E.L classification: Q50, Q54, Q56

The environmentally caused issues and consequences can turn from ecological problems to political, economical and peace threatening problems.

The economy of the world has a strong relationship with the environment and any small change in the environment may be immense.

Furthermore, if one environment issue occurs in one region or in one country, it will affect the neighborhood and in time it will affect the whole world, if not prevented or resolved.

The causes of the climate change are numerous. They can vary from solar radiation, changes in the greenhouse gas concentration, the movement of the Earth's orbit, continental drifts.

Some of the causes of the environment changes are: the climate change, glacial melting, sea level rise, floods, the reduction of arable land, loss of territory, increased drought.

Several consequences of the environment changes are: water and food shortages, migration or population displacement, the inability of a region to fulfill the needs of its citizens, increase in mortality, damage to ecosystems.

Other conflicts can be also caused by the discovery of new resources in some parts. A very good example of this situation is the discovery of an important oil resource in the arctic region.

When we state the words "climate change", it has to be crystal clear that an apparently insignificant change in temperature, for example, an increase of 2 degrees Celsius in the global temperature would lead to glacial melting that would result in an increase of 20-30 feet in the sea level, which would lead to the loss of the territories, which would furthermore affect all the aspects of our lives.

The last consequences could be minor, or they could create wars and conflicts. Moreover, analyzing in depth this increase in temperature, diseases like malaria and dengue would be spread all over the world.

Other consequences of the rise in temperature would be violent heat waves, animal extinction, increased desertification, water scarcity in other parts of the world and so on. Imagine all of these problems.

All these issues represent a major threat to the global economy. The most intriguing fact

is that even though these problems are well known, they have been slightly ignored. It is only in the recent years that international organizations started to study these problems and started to ask questions regarding these problems. They are not the matter of a single region, but they are worldwide problems.

One of the main problems in order to prevent and to respond to these issues is the lack of communication.

Many countries denied to give any clear data regarding their position and situation and a clear worldwide analysis cannot be yet developed.

It is of a high importance to have accurate data, as a problem cannot be completely solved if not all the details are known.

Furthermore, future strategies should be created. The developed world heavily relies on fossil fuels, which are very harmful for the environment.

This reliance is not only harmful for the environment, but it is also a cause of dispute between countries, as the competition over resources is high. Contemplating this issue, new alternative technology should be developed. This requires further investment in research.

Regarding the water shortages, it is strongly recommended that the international community to persuade the leaders of the world to sign agreements.

Peacekeeping is vital. When stating this affirmation, think about the fact that countries that are facing problems with water shortages and countries that are facing problems with flooding should sign agreements to share their waters.

Another concern should be the waste management. One example is food. Due to economical, political reasons, a lot of food is wasted. In developed countries, if you go in a supermarket for example, all the vegetables will be perfect. If they do not have a perfect shape, they are thrown away. This is just a small example. What if those vegetables would not be thrown away and what if the relationship between supply and demand would be one that shows the real needs of an individual. What if the suppliers would give the consumers the exact quantity of what they need, without having any excesses and without wasting anything?

This action could influence the food dilemma in certain areas. In addition to this, resources are limited and this action could also help in stretching the duration of the resources and giving the chance to the leaders and to different organizations, which are involved in finding and applying the responses for the problem, to have more time.

Moreover, if we think about the fact that some countries, for example Iraq, have changed the courses of their waters for military purposes, idea of creating new drainage systems could be feasible. Peacekeeping and investments in research and in installations are needed. New strategic planning is equally important.

Environment diplomacy should be created and alliances between governments, NGOs, private companies, IOs should be made. Another idea would be to create an outer-space security. This could help not only in supervising the environment, but it could also help detecting the data that other countries do not want to reveal.

What is more, governments and organizations should also focus on space pollution, nanotechnology, nuclear, chemical and biotechnology labs, as they may be a very important ally or the worst enemy.

The global economy is in a strong relationship with the climate changes and with the environment.

Some of the most important economic indicators are the unemployment rate, which is strongly affected by the political situation and by migration, which can be strongly influenced by the environmental changes.

Furthermore, if we think about the recent issues that occurred in Japan and in the Middle East, Japan being the most recent and clear example of natural disasters which affected the environment on a global scale and the conflicts in the Middle East representing problems with more roots and consequences, including migration, conflicts over territories, political disagreement, wrong interpretation of democracy, deforestation, water shortages or floods (for example, the Nile delta is affected by the Mediterranean Sea which is going to rise the level of its waters and the Nile is very likely to lose an important part of its delta, which will lead to a shortage of arable land) and others, it is obvious that these conflicts are going to

affect the industries, which means that the industrial production growth rate will change its variation.

Moreover, all the indicators regarding energy are also going to change their variation: the yearly electricity – production, the yearly electricity – consumption, the oil production, the oil – consumption, the oil - proved reserves, the natural gas – production, the natural gas - consumption, the natural gas - proved reserves. As these situations need an immense aid, it is very probable that the yearly economic aid is going to change.

Thinking about the situation in Libya, it is obvious that the costs of the military expenditures are constantly rising, affecting the percentage of the GDP.

There are also some cross border indicators, mainly dealing with exports. As the near future of the fossil fuels is uncertain, the yearly imports and exports of the Middle Eastern countries are severely affected. This also includes a change in the partners of the imports and exports.

Nowadays substantial investments in the extraction of the petroleum from Brazil are done, as huge reserves of petroleum were discovered there.

It is very probable that in the near future Europe is going to change its imports and exports partners, regarding petroleum.

What is more, the public debt for some countries is going to increase, and others will not be able to pay this debt. One possible result would be the start of a new colonization era.

These examples with the Middle East, Japan and Brazil are not the only ones in the world, but their actuality is critical and they are best known by the whole population of the globe.

Due to the fact that nobody expected the natural disaster in Japan or the massive movements in the Middle East, it is of high importance to resolve these issues, to find feasible solutions, as the global economy is very likely to drastically change its course in a very short period of time.

Another important factor that affects the global economy and the environmentally caused conflicts is the financial crisis.

The financial crisis has also affected the environmentally caused conflicts as everything in our world today is strongly bonded with money. For example, if a lesser

percent of the GDP is attributed to investments, the labor force, the industrial production growth rate, and the cost of the military expenditures are going to decrease and if the inflation rate is going to increase, the environmentally caused issues are going to take a longer time to be solved.

This can lead to a worsening in the scale or in the impact of the environmentally caused issues and in the environmentally caused conflicts. Enlarging these issues is surely going to have a higher impact on the global economy.

It is not unknown that our world is divided in developed and less developed countries and that the less developed and the developing countries depend on the well developed countries.

In Asia, one of the most developed countries is Japan, which is also part of the G8. The countries in the G8 represent 14% of the world population, but it has to be underlined that these major economies (Japan, France, Germany, Italy, the United Kingdom, the United States, Canada and Russia) represent 60% of the gross world product. If one of these super powers fails in any way and if it does not manage to rehabilitate itself very quick, it may have fatal consequences for all the economies, regardless if they are developed or developing.

The problem today is that more developed powers are shaking and it is premature to say how it is going to end.

Conclusions

To conclude, the relation between the environment and the global economy is very tight.

Every small change in the environment affects the economy and even though researchers might have future analysis and plans, these analyses can be overturned by any change in the environment.

The global economy was and will always be a major challenge as it depends on a multitude of factors that constantly change.

Some researchers and analysts are trying to make different strategies and they are trying to simulate different possible situations, with the data they already have.

But here they have to deal with another problem: not all the leaders of the countries agreed to share the data which the researchers need, so sometimes it can be impossible to create any strategies or to simulate some situations.

Many answers are going to come with time, as the technology will advance. But it is not to forget that the environment is always going to change.

Partnership between the U.S. and the E.U. through the Doha Round Agenda

Albu Gina

„Alexandru Ioan Cuza” University of Iasi,
Faculty of Economics and Business Administration
ginaalbu@yahoo.com

Abstract

In this paper we address the issues underpinning the transatlantic relations through the Doha Agenda. It refers to issues such as agriculture, services, trade facilitation and not least the problems and not only

Key words: Doha Round, negotiation, free trade area

J.E.L classifications.: F59

1. Introduction

EU-US partnership is an important step on the stage of world economy.

Although the strategic interests of the United States and Europe are largely similar to Europe in recent years offended that the U.S. has focused more on the wars in Iraq and Afghanistan, and on China

2. Doha Round - awaiting confirmation

Fourth WTO Ministerial Conference held in Doha, Qatar from 9 to 14 November 2002. The main items on the agenda of the conference was the negotiation and adoption of the draft Ministerial Declaration, which includes future WTO agenda, namely the main actions that the organization's 142 members intend to focus in the coming period, including the proposed multilateral talks. At the end of the Conference, Ministers adopted a formal declaration present, the Doha Development Agenda, which was also the work program for the future. It essentially aims the following aspects:

- In agriculture - are proposed to extend negotiations on market access, reduce - to remove - all forms of export subsidies,

substantial reduction of domestic support which adversely affect trade, taking into account the concerns of non-commercial;

- In services - continuation of negotiations to liberalize market access;

- Trade in industrial products - the initiation of negotiations to reduce and eliminate (if any) of customs duties, tariff peaks and tariff escalation;

- As regards investment rules and competition - launching a training program for future negotiations on these issues, trade facilitation - to initiate negotiations to facilitate customs procedures and increase transparency;

- In the rules on dumping and subsidies - the initiation of negotiations to clarify existing rules, e-commerce

- Continuing work already started, but maintain the current moratorium on customs duties not to impose electronic transmissions;

- In the settlement of disputes - the initiation of negotiations to improve and clarify some existing provisions of the Memorandum of Agreement, trade and environment;

- Continuing work on the analysis, labor standards - the International Labour Organisation recognition as the most appropriate forum to conduct a dialogue in the field, acknowledging the work undertaken by this organization on the social dimension of globalization, development dimension - ensuring access market improved least-developed countries, and ensuring more hardened provisions regarding special and differential treatment for this category of countries. Top round of talks in Qatar, in November 2001 was marked by hostility between rich and poor. The goals are worthy, hopefully the results will be comprehensive. Doha aims to reduce distortions in agricultural trade, to reduce tariffs and remove subsidies on agricultural

exports, to eliminate duties on industrial products, especially in areas where poor countries have an interest (such as textiles) to facilitate trade in services and to negotiate global rules in new areas such as, competition, investment and trade facilitation.

3. Cancun Ministerial Conference

The Fifth WTO Ministerial Conference held in Cancun, Mexico, beginning on September 10 and continuing until 14 September 2003. Conference in Cancun was designed to represent the middle of negotiations launched at Doha in 2001.

At the conference in Doha it was decided that the fifth meeting of the Ministerial Conference to review progress, provide political guidance in a number of areas included in the Doha Development Agenda (DDA - the Doha Development Agenda Round), including decisions on four subjects in Singapore, namely: the relationship between trade and investment, interaction between trade policy and competition, transparency in public tendering procedures and commercial facilities.

At the conclusion of the Conference on 14 September 2003 adopted a Joint Ministerial Statement which states that there are many things to do in different areas and recommends further discussions and negotiations. According to *The Economist*, some trade officials question whether their failure in Cancun, which comes less than four years after the failed ministerial meeting in Seattle in December 1999 would mean the end of the WTO as a forum for negotiations."

Analysts believe that the failure of the Cancun meeting was due to the intransigence shown by both the participating countries, be they rich and poor, and behavior considered to be "irresponsible and irritating" non-governmental organizations (NGOs). NGOs have accused rich countries that have tried to sabotage the talks, paying too little attention to the agricultural dossier.

In other news, the rich countries have found that NGOs played an important role in the radicalization of the conflict. These organizations have "flooded" with poor countries really confusing positions. The main mistake was that NGOs have increased the level of unrealistic expectation for poor

countries.

Finally it may be to blame would be the procedure of decision making in the WTO. EU Commissioner Pascal Lami, has likened rightly, the WTO with a "medieval organization 'whose rules and procedures can't support the importance of the tasks undertaken.

It remains to be seen whether the Doha round could be revived or not, certainly in time things will become clear and hopefully the results will be the best.

4. The safety of market

European Union and the United States should appreciate that their economic relations are at a crossroads. Disputes between Europe and the United States are intractable in terms of special global political and economic situation.

It would be foolhardy to believe that the transatlantic partners will be lost because of litigation. The WTO would not be able to solve these problems. Even worse if it goes to the WTO for arbitration this affects more than to give both parties a solution. Waiting for the Doha trade negotiations would be a waste of time still facing commerciale. A negotiations so disappointing, but true is that the WTO is not useful to strengthen transatlantic economic relations.

Ministerial Conference in Seattle (USA) from 30 November to 3 December 1999, was, in chronological order, the third after Singapore, 1996, Geneva, 1998. The conference will mark the launch of a new round of negotiations, suggestively called "Millennium Round".

The four days of negotiations ended with an outright failure. Reasons for failure of this conference were many. First, the time for carrying out conference was not well chosen because it coincided with the launch of the campaign in the U.S., the American delegation in this context, is not willing to make concessions, although this is a condition of any negotiation process. But the failure of the Conference has other deeper causes, since the 135 delegates of member countries failed to reach a common point on any of the issues in dispute, from agricultural subsidies, the "social norms", competition or environment. Blockage occurred amid disagreements between the U.S. and U.E.

between U.S. and Japan, and between rich and poor countries, for the first time in history the organization has not been exceeded. Included on the agenda were a number of problems, among which the most important agriculture and services were insufficiently addressed in the Uruguay Round, as well as two new areas, labor and the environment.

Agriculture was the main bone of contention between the U.S. and the EU, the latter being pressured to make concessions, higher than it was prepared, on agricultural subsidies. The Conference Director U.S. Department of Agriculture showed that each country has the right and duty to help farmers, but only so as not to distort trade, its disadvantage farmers in other countries.

Services have been discussed due to the need of further liberalization. Unlike agriculture, this was a field less controversial, this and the fact that the GATS allows each country to choose what services liberalization agreements wants to join. Disputes have arisen either in connection with the U.S. refusal to open its market for maritime services, the EU's desire to protect audio-visual services for cultural or developing countries to reduce restrictions on movement of persons. The sectors considered were: electronic commerce, shipping and air services liberalization and developing countries.

"Social rules" or "work rules" have been subject to fierce controversy, reflecting the differences between developing countries and the U.S.. U.S. have proposed a working group to examine the relationship between trade and labor law, so that trade liberalization does not lead to rising unemployment and falling wages. U.S. position on the need for cooperation between the WTO and ILO (International Labour Organisation) has been supported by EU and Japan, but challenged by developing countries.

Advancing humanitarian arguments, U.S. asked to give up the low wage policy, which allows the sale of goods on the international market at lower prices, competing as western products. U.S. but did not mention anything about the pocket that could be paid higher wages for workers in poor countries. The more so since both the U.S. and other developed countries have refused to comply

with UN recommendations, to allocate 0.7% of GDP to help poor countries. Environmental problem was the reason most anti-WTO demonstrations, environmental protection organizations (Greenpeace, Friends of the Earth) by claiming that globalization and liberalization of international trade have a negative impact on the environment. Because there is already a WTO working group dealing with trade-environment relationship, no new regulations were deemed necessary. It noted that European countries and third world countries have protested against the export of genetically modified American considered to be an attempt to address environmental and human health. The failure of the conference was considered a failure of the Clinton Administration's chief negotiator, Charlene Barshefsky and a victory, albeit temporary, protesters anti - WTO. WTO Director General Mike Moore, in a declaration made on 7 December 1999, stated that: "All I have left Seattle Friday disappointed, but not with fear that we will not be able to complete the task we were there. ... Discrepancies were significantly limited in some important areas. Ambassador Charlene Barshefsky said that the meeting was adjourned, but that work will be continued and completed. "The suspension of talks is not unprecedented in the history of the multilateral trading system. [...] I am determined to fulfill my duties effectively to ensure maximum possible participation of all members at the next meeting and as soon as possible to be able to announce the resumption of the Conference and then its successful conclusion."

5. A transatlantic free trade area

Ultimately it is the turn U.E. and U.S. to act. They need a transatlantic free trade area. Not because Taft is inevitable. The economic benefits would be considerable but not a range.

Between European Union and United States customs duties on industrial products are approximately 4% and therefore the lowest in world trade. Even if it would eliminate tariffs on agricultural products higher revenues would rise to 0.3% of gross domestic product of both regions. But nonetheless U.E. and U.S. Taffeta need. They need a sign for the future in terms of advancing transatlantic

economic relations. Taffeta could be a political symbol for a deeper economic relationship. This would compensate for the lack of credibility in the transatlantic partnership to bring the subject back to consciousness European and American politics and return it to the public eye. It is important that people understand how much they affect transatlantic relations of everyday life, despite differences in the world. This is what the European Union and the United States have not yet achieved. A transatlantic free trade area could help to reconcile their differences just because there are free trade zones. It should be an incentive for the transatlantic partners to participate in their disputes. It is understood that problems can not be solved overnight, but a bilateral agreement with EU and U.S. should be a forum, if not an obligation, to solve their understandings.

6. Recognition of the free market

A transatlantic free trade area is an opportunity for EU to be on an equal footing with the United States.

This gives the EU an opportunity to act strategically, something EU not done yet. It seems that strategic alignment is what offers a long-term competitiveness, not just in an economic way. Good economic relations and a transatlantic free trade area allows the EU to align with the United States and other trading partners like China.

A collision in the trade negotiations between the U.S. and China occurred in a dialogue on economic issues on 14-15 December 2006.

While S.U.A Trade Representative Susan Schwab said: "Asian economic model based on the fact that" Asian economic model of state control and huge amounts of exports was more suitable for China, which now should focus on domestic consumption rather than exports to achieve growth. "

7. Perspectives in world economy

In terms of major economic powers in the world ranking is confirmed a hypothesis that was stated in the late nineteenth century, the hypothesis was resumed in the early twentieth century, namely: displacement of the center of the world economy in the euro-

zone - Atlantic to the Asia - Pacific. This change is based on an objective question, namely: the growing exploitation of the huge human potential of all countries from the Holy Town and assimilation of new technical developments, thus facilitating the transmission of technological knowledge and information worldwide. It is expected that, to the extent of referral to the knowledge society, and many other nations to better exploit their creative potential and, therefore, to improve their place in the world economy as a whole.

Rapidly changing structure of international relations - rise of new powers (India, China), means that EU becomes a lesser part of a larger world. Even in a "bigger world" is certainly the European Union will remain a major player in the game in the world economy. This will always be compared with the two poles, USA and last but not least Japan.

In terms of world domination can say that there is only one superpower, the United States and four centers of power Japan, Russia, China and the European Union. None of these five players should not isolate themselves from others, to have a role in solving international affairs. Rather, each must ally with as many of the other four. This coalition will be able to unite three of the five will have the chance to impose its will in international affairs.

In a forecast covering the next 20 years, Boillot predicted that the fight for global economic leadership position will include three major forces, namely: China, EU and USA. Japan is not included in the analysis and this is perhaps a little surprising.

The economic world will be dominated by China which will be followed by Europe and the U.S.. Moreover, these predictions come true because even this year, 2011, China has become the largest producer of goods in the world. In this way and recovered the lost position in the early nineteenth century and ended 110 years of supremacy of the United States, according to a study published by the American company IHS Global Insight economic consulting.

Major currencies will continue to USD and Euro. And as the U.S. financial situation will be the first in the world followed by the European Union. In terms of technology and science leaders will be U.S. followed by

China. Europe will be noted by regulatory capacities and regionalism. In conclusion Boillot's forecast reflects the fact that the U.S. will maintain its political hegemony. Opinions are divided and there are forecasts that say that Asia in the years ahead will move the balance of power. In what follows I will present in the chart below how the share of GDP by 2025, this projection is estimated that since the U.S. share and U.E. will decrease by 2025 to below 25% of that of Asia will reach 40% and even exceed this value.

New World Order – Perspectives to Achieve

Albu Gina

„Alexandru Ioan Cuza University” of Iasi,
Faculty of Economics and Business Administration
ginaalbu@yahoo.com

Abstract

In this paper we have treated several fundamental issues underlying a new world order of political and economic perspective. I made a brief foray into what about the prospects of creating a new world order and ways to implement it. new world order is a fundamental problem in the global economy..

Key words : new world order, economic hit man, world elites, conspiracy theory.

J.E.L. classification.: F02

1. Introduction

New world order is a fundamental problem in the global economy. The world elites believe that the only way to maintain world peace is the creation. even if it is something else because the New World Order which means massive plans to reduce population, the destruction of sovereignty of nations and not least the end of democracy. Announcing these changes would not only open to massive protests and violence worldwide. Therefore, plans are kept secret shadow forces and their implementation is done gradually. It speaks in a conspiracy theory about the famous.

2. New World Order - Perspectives on to achieve

(...) "Between what you know and what you assume you do not know is what (...)".

The question that I would like to start is: Does the EU is a new world order that replaces the old nation states. If you want to know the answer to this question must identify key stakeholders and policy factors that influence the structure of interaction. Transgovernmental Networks is currently a

more important feature on the global economic scene than the new world order. Unfortunately the structure, processes and impact and horizontal impact international relations between nation states are currently unknown.

In the book "The institutionalization of Europe," Stone Sweet, Sandholtz and Fligstein (2001) offers a perspective that has the potential to overcome differences. They define political spaces as "social spaces where players meet to make the rules and interpret them, as they are sites of collective governance (Stone Sweet, Sandholtz, and Fligstein 2001, 13). This creates perspectives on so-called " skilled actors' " leading to the development and implementation of any type of political rule.

Besides all this talk about New World Order it is just a myth or a reality? Lack of information and abundance of certain others make us ask some questions and we tend to wonder where the truth actually is. Maybe it's somewhere in between.

The new millennium has brought with it a number of hopes, broken promises and an inclination toward what is worse. Since 2000, hundreds of billions of dollars have been spent on war while the international community pitifully low in terms of funding community projects.

The question we must address is whether a world is moving in the right direction. Even is someone who really wants these wars in Afghanistan and Iraq wars in which thousands of lives lost, they are wasting thousands of dollars and all this for the sake of mineral wealth in their possession and Afghanistan because of its geostrategic position with Central Asia's oil and gas, all that is happening because Iraq is the largest oil producer in the world.

The world elites trying to convince that the only solution to establish and maintain "world peace" is the creation of New World

Order, this is possible only through the unification of world powers. But the reality is quite different because the New World Order which means massive plans to reduce population, the destruction of sovereignty of nations and not least the end of democracy. Announcing these changes would not only open to massive protests and violence worldwide. Therefore, plans are kept secret shadow forces and their implementation is done gradually. It speaks in a conspiracy theory about the famous.

Are financial benefits for corrupt politicians and powerful pressure groups, are in fact used networks of activists that are positioned strategically and not least corporate information resources are used. They help to spread propaganda and cover up the truth, they demonstrate that preparations for the whole operation took a long time and planning. Lacking substantial opposition within the system and this reveals a certain network of volunteer collaborators who did no more than provide a "dirty job" and have infiltrated the system for what we call the world elite. Most times it seems quite unlikely that elites were able to expand their power and control over many posts here seem to have their origins skepticism and "theory" of conspiracy. Because all the changes going in the same direction exclude the possibility of a coincidence. In a society that continues to be free of any restriction, even if we speak of moral values, conformity and opportunism are wide spread. In times of economic crisis, New World Order becomes a reality before our eyes, no longer just a vague concept formulated.

The financial crisis is expected as the major commercial centers. This is emphasized according to a study by the Global Cities Index ", by researchers in management consultancy company AT U.S. Kearney together with Foreign Policy and The Chicago Council of Global Affairs. According to the study in the five cities that were highly globalized showed the greatest disturbance indices. Thus, cities that are at the top are the most affected by globalization in terms of bankruptcies and unemployment in the financial industry. The current economic crisis has its epicenter in major urban centers.

How can the IMF was expected make its presence felt by offering money. And how does that work? Nothing will simply print money. But the International Monetary Fund would be left without money if the number of countries applying for funding is becoming greater. Such requests come from all over the world, from Latin America, Africa, Asia and to Eastern Europe. A renowned expert on freemasonry Council for Foreign Relations (CFR), Brad Setser says that the need for external financing of all countries covered by the IMF is around 500-600 billion dollars, and draws attention to the fact that the sum would sink Full Monetary Fund.

IMF to get cash may give in his own name in financial markets, but this institution has not yet resorted to this option. He called at the request of deposits from the 185 member countries. A force majeure option is to print money by issuing Special Drawing Rights type, financial instrument used by the World Bank and International Monetary Fund. But resorting to such a measure could not only lead to rising inflation and soon no financial currency would not be worth anything.

Bilderberg Group could propose a financial solution that is dictatorship. The twentieth-century masonic secret protocol states: "Economic crises have been and will often be caused by even the new ability to withdraw money from circulation." French President, Prime Minister of Great Britain and senior international officials want a dictatorship in order to eliminate the current financial crisis. Even the skeptics have to acknowledge that the current financial crisis is used by those who seek to lead our planet is the reason to establish the New World Order, said this in 2008 at the Bilderberg meeting. Shortly after the end of the Bilderberg meeting, Timothy Geithner said in the Financial Times that because of the system are created serious financial problems. But financial and banking system was created by national who now wish to remove it. An example in this case is the U.S. Federal Reserve.

Any central bank has the power to issue money for a whole nation, and through this mechanism controls the rate. A central bank can borrow money and how the government was expected to make in return for interest.

No measures taken by the World Bank always will be the best but it seems that it is a tradition to intervene in these situations.

It seeks financial monopoly, and in economics we talk about three classes of industry. These are: natural capital, currency and credit. Natural Capital refers to the raw materials and energy sources, currency printing refers to "money" and credit refers to borrowing money with interest and not least the extension of bank deposits with economic value.

United States and most countries in the world have a well established system based on a "financial monopoly." Anyone is free to earn as much money as he wants, but will be paid only in the official notes. There is no way that can be paid in gold or any other form of money. Financial monopoly is held by some private banks, a relatively small number, which is owned by some of the richest families in the world. Their plan is to get to control a 100% all the world's capital resources, thus controlling everyone's lives through the availability of all goods and services. Possession of the independent sources of wealth in the hand of every person in the world could break all the plans he had with reference to global domination, and this is not a secret, here I am in possession of a free energy device.

In today's economy of a nation can be accelerated or slowed by lowering or raising interest rates. If there were an independent source in the economy that energy capital, and any person or business would have access to more capital without borrowing from a bank could lead to the elimination of interest rate manipulation. The amount of money is totally changed by the emergence of a free energy technologies. Either this is not desired by those who wish to have monopoly control of the present and the possible emergence of such a free energy must be removed and banned. The reasons they are made by "divine right to rule", greed and uncontrolled need to control things. They use intimidation as a weapon to delay the purchase and hiding technology, attempted murder and murder of inventors and the characters involved, arson and a wide range of incentives and inhibitors to manipulate the financial support of free energy. Scientific theory which states that free energy is impossible has been promoted all of them.

The emergence of such a free energy would be a nightmare for the government.

New World Order would mark the end of national self-determination, democracy, human rights and even end a number of public service, here including the education and health.

Announcing these changes would certainly lead to massive and violent protests worldwide. Thus, these are introduced gradually with a high degree of misinformation.

It aims to be handling it by distorting information in any form, from products, advertising that distorts the perception by consumers and media manipulation, false information about what is happening in the world, inducing error in the population in East conflict East and other civil wars, strategic disinformation, "EHM" (economic hit man) - taking over the misuse of resources because of the indebtedness of poor countries to powerful states - and, not least the handling of money through tax burden, defective and non-transparent policy lending banks, insurance companies etc..

A highly controversial case was the attack on September 11, which later proved, scientifically, that was developed from A to Z, by Americans.

Images from the spot where there was a so-called terrorist attack are not compatible with the damage done by a commercial airliner that was the size of a Boeing 757, also no witness can't recall having seen a plane crashed nearby.

Holes above the windows in the building products are inactivated, while firefighters stood in front of a perfectly round hole in the Pentagon's steel-reinforced wall, the hole that has less than six feet in diameter.

Apparently it was an explosion, caught fire, and firefighters rushed to arrive at the scene but found no airplane. Even bits of a plane. At a quick glance at the photos and videos of 11 September 2001 at the Pentagon, is quite clear that firefighters had fought a lot of fire that took about ten minutes, and the so-called rescuers were not involved looking for survivors alleged attack, although it is believed that there are many victims.

Pentagonal was too easy a target for attackers. It is quite strange that the radar would normally have to protect the world's

largest building has not detected a Boeing 757 that will be headed straight for the building. It is not known whether or not a coincidence, but no advanced missile system to protect the Pentagon from an air attack has not been in operation, although it is activated automatically when there is an imminent danger. Is it vital center of the largest nations on earth, unable to defend themselves? It's hard to believe.

Apart from that, the current television (CNN, ABC, etc.) transmit information to suit political force in government and big business interests, which does not sound good, does not give the news. Nothing simpler.

Another very important case is the pharmaceutical company has chosen to cancel the HIV medicines in Africa and Asia, though he knew the human error occurred. Drugs were withdrawn from the U.S. and European markets and redistributed in poorer countries, that it why: too many people there, some will not hurt to go away.

AIDS was created in the laboratory. There are many who believe that HIV was produced by scientists in particular. According to a conspiracy behind the creation of this virus would be the CIA, who wanted the launch of the disease among the population to destroy the American or African-American minority. This theory is believed by many people including a few figures. South African President, Thabo Mbeki, who has been alluded to a point in this theory and attempted to combat the disease could be the explanation that first appeared in Africa. He claims that the virus was created in U.S. military laboratories.

Nobel Prize winner, environmentalist Wangari Maathai, also supports this theory. Other variants of the conspiracy claim that the virus was created by the World Health Organization, this theory is supported by Dr. William Campbell Douglass, but would be an option that actually believes that the KGB would be back. Although researchers have not reached a common view on how the disease appeared in humans, most believe that the virus passed from monkey to man, this is possible through the '30s. In 1981 came the first reports on the AIDS epidemic.

3. Conclusion

Whether we accept or not slowly introduce the New World Order. Shadow Force makes its presence felt, and we do not know if we can do something to stop this.

Internal Audit - Pillar of Corporate Governance

Alexandru Georgiana
"Spiru Haret" University
georgiana19iu@yahoo.com
Constantin Nicolae Vasile
nicolae.constantin@medu.edu.ro

Abstract

Corporate governance represents the system through which a company is being controlled and managed. In defining of this concept, works on the idea overall performance of the company is based on the theory of interest holders.

The paper concerns about the relationship between corporate governance and internal audit, focusing on the role of internal audit within the economic entity, and thus in corporate governance, knowing that the value of a company maximizes in the extent to which managers succeed to identify and harmonize the conflicts of interest between the social partners of the firm, especially between shareholders and managers.

Key words: internal audit, corporate finance, corporate governance, internal control, risk management.

J.E.L. classification: G32, G34, M41, M42

1. Introduction

Debates around corporate governance intensified during 90's, first in Anglo-Saxons countries, then in continental Europe and further on international level, based on a primordial situation focalized on analyzing managers power and their limitations among every patrimonial entity.

The financial aspect of corporate governance lies in the use of this concept in practice of auditors, as prescribed by the International Standards on Internal Audit.

2. Corporate governance and its role in companies

Corporate governance represents a central and dynamic aspect of the economic reality, being increasingly sensed in numerous countries. Derivate from the Latin word *gubernare*, in Romanian the term of governance is synonymous with the term of administration, implying all the activities that enter in management field on an entity's level.

Corporate governance of Romanian enterprises and thus their performance trend can be analyzed and understood only through the development process of reform in the context of transition from planned economy to market economy, which led to profound changes in the microeconomic universe. In fact, the corporate sector has really emerged from the process of privatization of state enterprises, which were centrally managed based on some binding plans and not on requirements generated by the natural laws of economy.

As it regards the concept of corporate governance here are some interpretations:

- Corporate governance represents the ways in which providers of financial resources of a company shall ensure that they receive the expected benefits from making this investment [9];
- Corporate governance can be defined as all of the company's relations with its shareholders, or more broadly, society as a whole;
- By J. Wolfensohn, former president of World Bank, corporate governance refers to promoting fairness, transparency and accountability at the corporate level;
- According to OECD, Corporate governance specifies the distribution of rights and responsibilities among different categories of people involved in the

company such as board of directors, directors, shareholders and other stakeholders, and establish rules and procedures for making decisions.

The key problem as it regards corporate governance is the *agent problem*, meaning that managers have control over other's money. According to corporate governance principles, a good development of a firm activity requires that in the Board of Directors to exist non executive directors, i.e. persons not connected with the managers or majority shareholders.

In his business, company management will have to take account of conflicts arising from the *multitude of interests under the same roof* because, if not properly known and regulated may jeopardize its effectiveness. Managers are a particular group of stakeholders who, holding power management, are both judge and party, and must ensure other legal persons involved that wealth will be distributed among them in a fair and free of abuse way.

From a power perspective, corporate governance follows only to legitimize the authority exercised directly by the managers and the representatives of the inspection bodies.

For a long time it was considered that the Board of Directors can be seen as efficient if the shareholders are receiving with regularity their dividends. The vision has changed in a significant way, because in a company counts the most the firm's plus-value.

Therefore the content of modern corporate governance has become a complex financial dimension that emphasizes the role of managers and requires a new behavior in excluding superficial attitudes such as *controlling from a glance*, maintaining the financial advantages even in hard conditions, being concerned for the entity's financial result.

Transparency and protection of minorities aims not only fair distribution of risks within a business entity, but a proper functioning of the market in a broad meaning: it should provide strong mechanisms, depending on the governing bodies to act for shareholders by maximizing the economic value of enterprise [1].

3. Internal audit- function of corporate governance

The audit is a universal function. Although, its best known face regards the financial function, the auditing activity spreads its arms among all functions retrievable in an entity, through internal audit, which covers all functions which contribute to a result determination. A limitation of audit activity to a single compartment, as accountancy, is not recommendable in the context of a globalized society, being preferable a complete verification and certification of the entity's activities.

Internal audit is an independent activity, objective, assurance and consulting, designed to create value and improve an organization's operations. It assists the organization in achieving its objectives by implementing a systematic and disciplined approach in evaluating and improving the effectiveness of risk management, control and governance processes [2].

Therefore, internal auditing represents a function integrated in the company, when the external auditing represents an independent function whose mission is to certify the accuracy of the accounts, results and financial situations, and more precisely to certify the sincerity and a truthful image of the financial situation and (if we retain the definition of the authorized accountants) to certify the regularization, ingenuity and fair picture of accounts and financial situation.

The concept of corporate governance is sustained by internal audit, which has an important role in assisting the reorganization of the internal control system and in advising general management.

The installing of a system in order to prevent fraud remains in the responsibility of the management within the organization and internal audit provides assistance in assessing risks and strategies for corporate control, suggesting the proposals, recommendations and solutions to diminish the threat of fraud, and improve the control strategy.

Ignoring the internal audit function can lead to real disasters in financial terms and not a few have been cases where the collapse of giant companies resulted in a number of negative chain and entailed thousands and

sometimes even millions of creditors, suppliers, employees and investors injured, with effects that have lasted for years.

4. Internal audit's role in corporate governance

In an era of almost instantaneous transmission of information, as well as increasingly blurred lines of distinction between different schools of political thought, the auditor also has to keep abreast of developments and the wide ranging global debates on the most appropriate responses to the severe crises that seem to develop so rapidly, be they global warming, forest fires or currency gyrations. [7]

An internal audit function could be viewed as a *first line defense* against inadequate corporate governance and financial reporting. With appropriate support from the Board of Directors' Audit Committee, the internal audit staff is in the best position to gather intelligence on inappropriate accounting practices, inadequate internal controls, and ineffective corporate governance.

Internal audit departments need to ensure their organizational posture allows them to operate successfully on strategic issues. This means both the independence and the mandate to deal with significant, strategic business risks and issues. If inappropriately positioned within the company, internal audit deals with tactical issues and is viewed only at that level. Inappropriate positioning can also raise serious concerns about the overall independence of the function.

As mentioned before, any type of corporate governance, in order to be considered effective, it must provide appropriate control mechanisms for interventions in critical situations and in order to protect the interests of all users.

The most effective instruments in preventing frauds are to be considered management control and internal audit.

An effective internal audit function plays a key role in assisting the board to discharge its governance responsibilities. In that manner, internal audit delivers:

- An objective evaluation of the existing risk and internal control framework;

- Systematic analysis of business processes and associated controls;
- Reviews of the existence and value of assets;
- A source of information on major frauds and irregularities;
- Ad hoc reviews of other areas of concern, including unacceptable levels of risk;
- Reviews of the compliance framework and specific compliance issues;
- Reviews of operational and financial performance;
- Recommendations for more effective and efficient use of resources;
- Assessments of the accomplishment of corporate goals and objectives;
- Feedback on adherence to the organization's values and code of conduct/code of ethics.

Internal audit, as an integrated function in a company, holds an excellent position in order to bring sanity back to the financial markets and reports.[4]

The internal audit process is a permanent function within a company. In other words, auditors review operational controls and procedures throughout the year. An audit manager typically may draft an annual audit plan at the beginning of the year, define responsibilities and assign tasks to junior auditors. A manager usually communicates annual schedules with managers of areas under review. Corporate audits often focus on "high" or "medium" risk areas ("high" and "medium" indicate potential losses).

Internal auditors' unique full-time focus on risks and controls is vital to sound governance process and to sound financial reporting. According to statistics from international news and information organization Bloomberg News, in more than half of the 673 largest bankruptcies of public corporations since 1996, external auditors provided no cautions in annual financial statements in the months before bankruptcy. Many of bankruptcies in history, including Enron, Global Crossing Ltd., and Kmart Corp., followed annual reports with clean audit opinions from the external auditors. Although external auditors' independence is protected to some degree, they still face many of the same issues as internal auditors

when it comes to undue management influence. [3]

This demonstrate that the larger and more complex the company is, the more difficult it is for external auditors, management, and boards to have an accurate picture of risks and controls. Here is where internal audits should interfere. Internal auditors play a vital role within governance processes by keeping the board, senior management, and external auditors aware of risk and control issues and by assessing the effectiveness of risk management.

Regardless of the integrity of the internal and external auditors, the fact remains that management continues to have great influence on the compensation and retention of both parties. Audit committees typically rely on the advice of senior management in evaluating the audit team's performance. Frankly, it is difficult to do otherwise, as the directors interact more often with the executives and rely on them to run the corporation. At the same time, few auditors--especially the internal auditors--relish the prospect of confrontation with senior management.

Internal audit reports provide top management, departmental heads and segment-level employees with relevant information about operating processes and weaknesses. Such data is important because it helps various readers understand potential risks (and losses) that typically may affect a company's operations

Internal audit scope should be extended to address strategic business issues as well as increasing some compliance audits.

Abstract

This paper's target is to point the role of political risk in international affairs. Despite the fact that now we live in a globalized world the reality shows that national borders still matters.

In this context, multinational companies face a lot broader types of risk when they invest abroad. One of this risks is political risk and that's because politics influences how markets operate. Often the most unpredictable economic events are political in origin, the result of inconsistent political decisions or incapacity to maintain a stable and predictable economic environment.

The importance of assessment and management of political risk exposure is highlighted by a theoretical framework that outlines the multidimensionality of the concept. To illustrate the framework and the complexity of the political risk phenomenon, a number of 2 case examples are presented from the international oil and gas exploration and production industry and the energy sector.

Key words: risk, political risk, foreign investment, multinational companies

J.E.L classification: F21, F23, G32

1. Introduction

Nowadays it is a fact that exists a viceversa relation between politics and economic. But when we talk about foreign investment political field stands out because of his impact on the decision of multinational companies to invest or not in a specific country.

Today's events, the turmoil in Africa, brings back in the highlights the principales types of political risk and here we refer to

war and civil disturbance, that can affect the operations of a foreign investor in developing countries.

Political risk is an evolving concept. In the 1970s expropriation dominated discussions; in the 1980s the debt crisis moved to center stage; in the late 1990s the meltdown of developing country capital markets was the predominant theme. Since September 11, 2001 the main topic of political risk was switched on terrorism and on friendly and unfriendly nations.

In this context our study tries to point the main theoretical issues regarding political risk and foreign investment and trough some case studies to demonstrate that an inappropriate assessment of political risk brings major loses.

2. Political risk and multinational companies – theoretical framework

The implications of capital controls in international business are just one aspect of the uncertainties or risks involved in doing business outside a firm domestic market. The risks that face a MNC in an international environment are largely debated in quite a number of studies focused on assessment of such risks.

Here we can discuss the theoretical approach on country risk and political risk. First of all country risk is a broader measure of international risk than political risk including besides political risk, credit risk and other economic measure.

Throughout the literature there is little consensus on a "clear-cut" definition of political risk [2,4,5,7,8]. Still two characteristics resides when we analyze the concept of politic risk: the instability of a political regime and the uncertainty of the policies pursued by such a regime. It should also be noted that the crystallization of the

concept of political risk takes place in a period of history, 1960-1970, characterized by violence (coup, revolutions) and/or dramatic shifts of politic regime, when the nationalization and expropriation where the principal types of risk in international business.

Probably the most restrictive definition on political risk belongs to Kobrin (1979), one of the first academic who debated this issue. He observed that the most used statement for defining political risk is "the host country interference in business operation" or "political acts or constraints imposed on the firm" such as creeping expropriation, devaluation and revaluation, foreign exchange controls and foreign wars [8]. Thereby in 1982, Kobrin defines political risk as politically generated circumstances which may have significant implications for the MNC management [7].

Simon views political risk as "governmental or societal actions and policies, originating either within or outside the host country, and negatively affecting either a select group of, or the majority of, foreign business operations and investments"[14]. Howell dichotomizes political risk definitions in terms of those that require acts of national governments and those that include political acts not originated by governments, such as rebellions.

Political risk that firms face can differ in terms of incidence as well as the manner in which political events affect them. Depending on the incidence, political risk can be classified into two types: (a) macro risk – where all foreign operation are affected by adverse political developments in the host country and (b) micro risk – where only selected areas of foreign business operations or particular foreign firm are affected [4].

At the macro level, firms attempt to asses a host country`s political stability and attitude towards foreign investors. At the micro level, firms analyze whether their firm-specific activities are likely to conflict with host country goals as evidence by existing regulations. The most difficult task, however, is to anticipate changes in host countries goals priorities, new regulations to implement reorder priorities, and they likely impact of such changes on the firm`s operations [13].

The distinctions between different categories of political risks are summarized in the table below.

Table 1. Classification of political risk

	Government Risks	Instability Risks
Firm Specific Risks	Discriminatory regulations	Sabotage
	"Creeping" expropriation	Kidnappings
	Breach of contract	Firm-specific boycotts
Country Level Risks	Mass nationalizations	Mass labor strikes
	Regulatory changes	Urban rioting
	Currency inconvertibility	Civil wars

Source: modified after Simon (1982)

The analysis on political risk includes some key factors as [12]:

- The host country`s political and government system – if a country has a lot of changes in government, the policies supported by the government may become inconsistent and discontinuous, creating political risk.
- History of the political parties and their strength – this analyze reveals the way of how a particular party run the country; the history of a party shows if he has nationalistic or liberal believes and the way he handles foreign assets. This analyze also reveals what can happen if a party or another wins the elections.
- The host country`s ethnic and religious stability – is well known that are a several countries with problems on the ethnic or/and religious field such as Northern Ireland, Nigeria, Turkey,

Israel, etc. These issues could have a great impact on the international operations of multinational corporations, especially those who exploit natural resources.

- Regional security
- Keys economic indicators
- Integration in the world economy

One of the most important ways to avoid any problems in the future is signing on well negotiated investment agreement between the foreign firm and the government. The presence of MNCs is as often sought by development-seeking host governments as particular foreign location sought by MNC. All parties have alternatives and so bargaining is appropriate [14].

Also political risk has an important impact on the value of MNC. Kyaw, Manley and Shetty argue that greater the political risk, the lower the market performance of MNC as measured with Tobin's Q equation.

The easiest way to manage political risk is through insurance companies specialized in the area. There are, however, alternative ways to protect a company against political risk, for example through risk preventive- and loss-limitation measures. Another method is to form a partnership with one or several parties.

3. Political risk – a major constraint to foreign direct investment in developing countries

The developing world absorbed about 37 percent of global FDI flows in 2009 - a proportion that has risen over the past decade and is expected to continue expanding. After appearing of the global crisis in 2008, FDI inflows to developing countries slumped by 40 percent in 2009 - a decline similar to high income countries - \$354 billion (2.1 percent of GDP), compared to \$587 billion (3.4 percent of GDP) in 2008.

MIGA (Multilateral Investment Guarantee Agency) 2010 report on *Political Risk and World Investments* shows that MNCs investing in developing countries rank political risk amongst their top three concerns more often than any other preoccupation, including macroeconomic stability and access to finance [15].

Referring to the types of political risk that multinational companies think that will face in the next year regulatory changes followed closely by civil disturbance in developing countries.

The global survey made by MIGA indicated that more investors are concerned about breach of contract, non-honoring of government guarantees and adverse regulatory changes—which can result in investment loss—than outright expropriation [15].

4. Case studies

In this section of the paper we illustrate the kinds of political risks multinational companies face in international environment.

So we present 2 case studies representative for the natural resources exploitation industry. The first presents a case from the oil and gas exploration and production industry and the second one from the energy sector.

a) The Russian experience of BLACK SEA ENERGY LTD

If in the '60 and '70 the principal type of political risk was expropriation without compensation, the major problem of the '90 was the lack of consistent legislation and proper law enforcement and no willingness on the part of the government to enforce contracts and protect private property.

For the illustration we choose the case of Black Sea Energy Ltd., a Canadian oil exploration firm [9].

The company in cause jointly formed Tura with TNG in 1996, through a Russian closed stock company, to enhance production at the Kalchinskoye oil field in the Tyumen Region of western Siberia. At that time, the Russian government held a controlling interest in TNG's parent Tyumen Oil Company (90%).

So Black Sea Oil negotiated the joint venture directly with the central Russian government. Each member in the joint venture agreed to contribute about USD 50 million, Black Sea Energy in the form of cash as well as new technology and expertise unavailable to Tyumenneftegaz. The Russian partner contributed in the form of infrastructure projects and the licenses for the oil and gas production of the Tura oilfield in western Siberia [9].

During 1997 and the first half of 1998, was achieved substantial technical success at the Tura Project. The introduction of western capital and technology to the project resulted in daily production at the field more than doubling, from 4,900 barrels of oil per day to 11,500 barrels of oil per day [17].

On June 11, 1997 the shares were listed on the Toronto Stock Exchange, trading at CAD 4.65. In August 1998, the share price was CAD 0.12.

So what happened?

In May, 1998, shortly after the privatization of Tyumen Oil Company, its new owners began to assert direct management control over TNG and began to dispute the terms of our Tura joint venture (the new owners thought that the original deal was not fair to them and wanted it cancelled). They then commenced a number of legal actions against the Tura joint venture company in the Tyumen regional courts challenging the validity of the foundation agreement which created the Tura joint venture company and the transfer from TNG to the Tura joint venture company of the licenses required to develop the Kalchinskoye oil field [17].

Although the operations had a real success Black Sea Energy Ltd. did not only not earn any return on its investment, but the firm faced expropriation of its initial investment due to political problems.

They found some conflicting legislation on the legality of the oil exploration license that was held by Tura and argued in court that the licenses belong to Tyumenneftegaz and not Tura Petroleum. All courts, the Ministry of Natural Resources and the arbitration courts in Russia consistently ruled in favor of Tyumenneftegaz, even though the joint venture was originally negotiated with the Russian government.

In early 1999, Tura succeeded in negotiating an interim sales agreement with Tyumen Oil Company, with the assistance of the Russian Ministry of Fuel and Energy. This agreement facilitated the sale of 1998 year end inventory as well as production through the second quarter of 1999. While the terms of the agreement were unfavorable to Tura, oil sales produced cash flow which allowed Tura to maintain oil field operations while the dispute continued. This interim agreement expired in June, 1999.

In June 1999, Black Sea Energy Ltd. finally initiated an arbitration at the Stockholm International Arbitration Tribunal suing Tyumenneftegaz for willful breach of numerous provisions of the Tura joint venture charter and seeking an award for damages of more than \$110 million representing the initial investment and the future profits [17].

In August, 2000, the firm entered into a settlement agreement with TNG, Tyumen Oil Company and Stesana Enterprises Limited. Under the terms of the settlement agreement, Black Sea Energy Ltd. disposed of all of the outstanding shares of the two Cypriot subsidiaries through which we held our interest in Tura and in the adjacent Radonezh exploration project. As consideration, the firm received approximately \$29 million in cash from the acquiror, Stesana. They also agreed with TNG and Tyumen Oil Company to terminate all legal proceedings in Russia and all proceedings in connection with the Stockholm arbitration [17].

b) The Indian experience of ENRON

On August 3, 1995, the Maharashtra state government of India, dominated by nationalists, canceled Enron's \$2.9 billion project in Dabhol, located south of Bombay. Immediately after the news Enron's share price fell about 10% [1, 2].

Enron became involved in this project in 1992 when the country was ruled by a new reformist government opened to foreign direct investment in infrastructure. Enron signed then in just 10 days a memorandum of understanding for building the Dabhol power complex. After signing the deal, the Maharashtra State Electricity Board agreed to buy 90% of the power Dabhol produces. Two other companies, General Electric and Bechtel Group agreed to join as partners for the Dabhol project [13].

The mistake that Enron made at that time was that the firm didn't correctly estimate the power of the opposition, nationalist and against the foreign investment, who won the election in 1995.

The first thing that new political power did was to reconsider the deal with Enron and with all the other foreign investors in the country.

With all the fight did by Enron to keep the details of the contract, the firm lost in court and it was obligated to reveal the deal made. The rate of return of investment was far higher than 16% over the capital cost that the Indian government guaranteed to others companies, so the critics argued that Enron had overestimated the costs and the fact that the contract involved corruption.

The new chief minister canceled the project citing inflated costs and too high electricity rates.

Enron already invested \$ 300 million and in a last effort the company involved the U.S Energy Department to make a statement in June 1995 to the effect that cancelling the deal could adversely affect other power projects. The Indian government criticized the statement [10].

After months of negotiation, Enron and the Indian government agreed to revive the Dabhol project. The new contract required that Enron cut the project's cost from 2.9 billion to 2.5 billion, lower the proposed electricity rates, make a state-owned utility a new 30% partner of the project and to withdraw a lawsuit seeking \$500 million in damages from Maharashtra for the cancellation of the Dabhol project [2].

5. Conclusions

Lower costs, new opportunities, and access to resources draw the companies to expand into international markets. If the decision of investment abroad is made the facts often shows that the politics of foreign environments adds risk and complexity to business performance.

All companies takes the political environment into management because businesses are often affected by political decisions in the countries where they operate especially abroad.

Political risk facing foreign direct investors is the probability of disruption of MNE's operations by political forces or events originating in either host countries or home countries, or resulting from changes in the international environment. In host countries, political risk typically refers not only to uncertainty over government's and political institution's actions that affect foreign direct investors, but also to dynamics that could result in civil disturbance,

terrorism, civil wars, and cross-border conflict. Because of its longer-term nature and assets on the ground, foreign direct investment is often more vulnerable to political risk than are other types of cross-border capital flows [16].

Perceptions of political risk also condition investor's willingness to invest in developing countries.

The numerous cases of loses due the manifestation of different forms of political risk makes political risk the most unpredictable risk in international business.

Further research is necessary because of the multidimensionality of political risk and the fact that is an evolving concept in an evolving world.

2020 EU Agenda – A New Lisbon Strategy

Amarandei Cristina Mihaela

Postolachi Andrei Teofil

"Alexandru Ioan Cuza" University of Iasi, The Doctoral School Economics

mihaela.amarandei@gmail.com

at.postolachi@gmail.com

Abstract

European Union is an example of the most advanced economic integration. While talking about a fairly long process, over 50 years, Europeans have adopted the tactics of small steps, but also well coordinated. If you think at any important moment of the European Union such as the realization of the single market or single currency adoption, all of this moments have been announced by the implementation of previous strategies. We are talking about strong and complete strategies, such as the last biggest ones: Lisbon and 2020 strategies. This paper proposes to give and build a synthetic profile of the two strategies, because of the link between them. The 2020 Agenda comes up with recommendations and directions, from which most of them had been found in the Lisbon Strategy.

Key words: Europe, Lisbon strategy, 2020 Agenda, knowledge economy

J.E.L. classification: F15, F43

1. Introduction

In the beginnings of 2000, in the capital of Portugal, appeared the Lisbon Agenda - a strategy for promoting economic growth in the European Union, which aimed to implement a set of measures at the continental level that should have led in 2010 to a dynamic and complex economy, the most powerful and efficient globally. The guidelines of this strategy were taken from the American model, which enjoyed a huge and spectacular progress in the period after 1990's. Mainly, this progress refers to the start of a new era in the economic field: the new knowledge society, based especially on

technological progress. So the European officials were ready to take part of these U.S. methods.

But not the U.S. model was the principle cause of adopting the Lisbon strategy mainly because it was seen firstly as an Agenda that will continue the integration process in the European continent. Considering the complex and advanced integration process, namely completing the stage on the trade for first – with the creation of custom union, and then creating the single market, followed by monetary union – by euro adoption, the next target is linked to the final stage, the political union. In many of its aspects, the strategy was seen as a "frame" in which the integration process would become deeply advanced, especially at the political level.

Anyway, though ambitious in the beginning, both proposing objectives on the economic, social or political level, this strategy experienced the economic imbalance generated by the economic crisis that we are facing in this period. So, next we are intending to make an overview on the failure of the Lisbon Treaty, and then to mark the main aspects concerning the 2020 Agenda of the European Union.

2. The failure of the Lisbon Strategy

In 2000, European Union (EU) leaders launched the Lisbon Agenda to turn the EU into "the world's most competitive knowledge-based economy" by the year 2010, and by 2025 into a "sustainable knowledge-based society". To achieve this goal it emphasized the transition to a knowledge based economy and society, structural reforms to increase competitiveness and innovation, completion of internal market, modernizing European

social model, investing in people and combating social exclusion, sustaining healthy economic outlook and favorable growth prospects by applying appropriate macro-economic policy mix [3]. The key elements of the agenda were: research and development (R&D), lifelong education, information and communication technologies (ICT), liberalization to create a single market and entrepreneurial culture and jobs-led growth leading to improved social cohesion [8]. Taking all these purposes into consideration, we can affirm the complexity of the strategy, which had in one way or another a clearly view on the evolution of the developing process.

As it is noted above, the Lisbon strategy was following a certain similarity with the American model of economic development linked mainly to technological progress and move towards a knowledge society. The difference here was the application of these criteria, that the United States were developing these new information technologies especially linked to private domain, the introduction in the production process to achieve decentralized, unlike Europeans who approached a reverse tactic from top to bottom, putting the public sector, the government actions in the spotlight.

The Lisbon Agenda can thus be considered an exercise in policy coordination. Such an exercise needs to ensure that Member States over-regulated economies comply both with the Single Market and with an adequate European-wide institutional environment for sustainable growth[2], so it can be seen as an exercise of greater collaboration, despite de high level of economics, improve the political aspects of the Union.

Thus the results of this strategy were not the one projected, due to a multitude of factors that have occurred during the implementation, of which the most important is the financial crisis started in 2007-2008, who had strong structural effect and has undergone world of new challenges. Ann Mettler (Executive Director of the Lisbon Council for Economic Competitiveness and Social Cohesion) said: "The problem was that Lisbon 2010 program was not pursued. It was an inconsistency between policies and budget. EU speaks about innovation, but half the budget goes to agriculture."

However, this strategy has represented mainly a passageway through which the EU should have approached to a greater development in the economic and social sectors. In some way this passageway has been narrowed, because of the recent economic and financial crisis.

The Lisbon project has represented a first attempt to find a new compromise through a broad strategy, appeared as a mechanical addition of different aims and goals rather than the solution to such trade-offs. Specific issues are related to the broad policy agenda; the tensions between budget, economic, employment and welfare reforms; and the need to focus more on social and labor market policy. The governance introduced through the Lisbon strategy is still in need for improvements. The aim of increasing participation and transparency seems far from being solved. EU democratic legitimacy has not significantly improved through the strategy, even if improvements in facilitating new forms of meaningful participation of civil society at the domestic level have been discerned [6].

3. A brief look over the 2020 Agenda

The European Commission has launched a new project last year, which comes to replace the Lisbon one, keeping most of the objectives, among which we approach 3 main ways taken into consideration:

- Develop a comprehensive labor market - flexibility balanced social assistance (the concept of "flexicurity");
- Building a "green and competitive economy";
- Promote a "knowledge-based economic growth." [4]

This is actually the growth strategy of the European Union during the next decade. In a world constantly changing, and sometimes cyclical, the EU needs to move to a sustainable economy, coherent and comprehensive to meet the challenges, but especially for the States to drive high levels of productivity, level of employment and social cohesion. This refers to a division of duties and responsibilities of all levels of decision-making, at local, national, regional to the European one, so all they can "reflect the high quality and accountability, and that all important drivers of change - business and

universities to work in partnership with local, regional and civil society "(extract from European Parliament resolution of 16 June 2010 on the EU in 2020).

The Europe 2020 Strategy renews the underlying approach of the Lisbon Strategy, based on a partnership for growth and job creation that relies on a mix of the commitment of member states to take action at the national level with making best use of Community instruments at the EU level [1], keeping in the same time the old will of achieving the political union.

Typically, the EU always brings into question strategies, ways forward, intricate plans, presented in multiple speeches and found in various official documents. Even if the Lisbon Agenda on the other side had encountered reluctance among the population in some EU countries, official voices are more optimistic about the success of this approach. They are therefore included a number of criteria by which to measure the degree of achievement of objectives for 2020: a 75% level of employment for the adult population, reducing carbon emissions by 20%, poverty reduction, mitigation early school leavers and increasing the share of college graduates, and most importantly a rate of 3% of GDP given field of research - development.

This area is important because represents the key element of knowledge, which comes mainly as a result of elaborate research process effectively. Such quantitative criteria set out above may be considered within the scope of relativity; even Gert-Jan Koopman (Director of Department of Economic Evaluation and Structural Reforms in the European Commission) was stating that: "The problem is innovation and application, not the R&D spending". Should therefore be pursued mainly the applicability of research projects, to eliminate the interest for payment.

The results of the research – development (R&D) should be primarily applicable in reality, in the sense that they need to improve upon the various sectors. It should not be regarded as a purposeful process, but should be considered to keep it at a higher level to get better results. Of course, finances are a significant issue, requiring a minimum allocation of resources, but must be combined with efficient management

mechanisms to support research and to properly manage these resources results in the sphere of knowledge. Europe is in this regard, behind countries like U.S. or countries in Southeast Asia, both in terms of resources invested and in terms of cost effectiveness. European countries on the other hand must adapt their reforms so as to remove various obstacles that might interfere with the growth of innovative enterprises, offering favorable framework conditions and facilitating access to finance. This is linked to the 2020 Agenda vision in this sector, of achieving more and more quality information and knowledge in Europeans life.

The contribution of research to innovation is already widely acknowledged: some scientific discoveries have applications that can be turned into commercial innovation. However, the knowledge triangle (R&D, Education and Innovation Policies)[9], underlines the importance of considering also the reverse relation: commercial innovations can leverage research efforts by increasing their efficiency.

The main changes, in comparison with Lisbon, are the radical reduction in the number of indicators (which previously numbered 42 so-called "structural indicators") and the incorporation of the environmental dimension with the already accepted targets (20-20-20) [7] that are realizing in some ways a link within the two strategies.

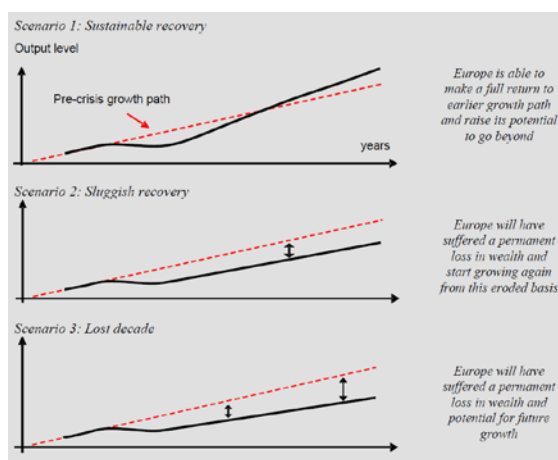

The knowledge-based economy has become the major trend in international society in the 21st century. Exploring the characteristics of the knowledge-based economy and establishing an appropriate economic paradigm for accelerating technological innovation is an urgent task for governments [5]. In their attendance of improving and avoiding the gaps of the Lisbon strategy, Europeans transferred the responsibility for action, which is needed to achieve the Europe 2020 goals, not only to governments, but also to all categories involved in the economic process:

- non-governmental organizations
- trade unions
- businesses
- local authorities and
- individual citizens.

The major reason why a knowledge-based economy can elevate national economic growth is that it can help construct a more effective production structure and improve the products and service quality further. Furthermore, the most obvious feature of the knowledge-based economy is its increasing returns to scale phenomenon [5]. So in the conditions of strong liberalization and internalization, each of the entities mentioned above, has to face a market economy in which "change" and "rapidity" are the main futures. So, in order to position itself as higher as possible on the market, each one has two options: do the "right things", and in the same time do "things right", both of them in the same time. This means a continuous enterprise adjustment of strategy.

Either we face up collectively to the immediate challenge of the recovery and to long-term challenges – such as globalization, pressure on resources, ageing, – so as to make up for the recent losses, regain competitiveness, boost productivity and put the EU on an upward path of prosperity ("sustainable recovery"). Or we continue at a slow and largely uncoordinated pace of reforms, and we risk ending up with a permanent loss in wealth, a sluggish growth rate ("sluggish recovery") possibly leading to high levels of unemployment and social distress, and a relative decline on the world scene ("lost decade") [4].

Figure 1. Three scenarios for Europe by 2020

Source: European Commission

As it can be seen in the figure above, there are 3 main scenarios that can provide some

information about the future of the European Union, related to the guidelines provided by the strategy for the next ten years. Of course there are a lot of variables that we should take into consideration to achieve at a realistic level of our assumption. It is obvious that on short term, all the indicators are depending on the evolution of the crisis, but hopefully, maybe after 2 or 3 years, Europe will pass the crisis, and so the future references on this aspect will not depend on weak indicators.

4. Conclusions

The knowledge economy is a relatively new term and in general represents a economy competitive, strong, stable, primarily based on managing a fairly consistent stock of "knowledge ". It is a process without finish in my opinion, meaning that it cannot assign a peak, a moment of maximum altitude, at the level of knowledge to reach a threshold level. Applicability of such an economy if the EU countries is a current and immediate need, mainly because of the problems they face today. On the other hand, as I mentioned above and the power of example is offered by other advanced economies of the world who have achieved not only economic benefits and applicability of a knowledge-based economic theories.

Strategy on training and education of a population with a high level of skill is essential to promote innovation and growth by investing in quality education, training and lifelong learning throughout life, represent the key to increasing the size of smart, sustainable and consistent economic European Union countries.

Even if the developed countries of the EU, particularly those in Western Europe, are more close to a knowledge society, Agenda 2020 is addressed to all 27 states and each country is free to consider the importance of the imposed criteria, and act within the conscience and the decision of local decision-maker.

We cannot yet talk about the existence of pure knowledge economies, because we cannot make a conceptual and practical separation, but, in the light of this strategy, I think the aim is rather in the manner of influencing the states to focus attention on

this segment, knowledge, and therefore we can say that the EU is moving towards the "knowledge economy", even if the purpose of this process cannot be predicted yet. Clearly, if we will face a failure of the 2020 Agenda, EU decision-making leadership will come with a new agenda in 2030, 2040 and so on, in their characteristic style.

Abstract

In the past 50 years tourism has become one of the most rapidly developing industries. But tourism has become a big cultural and environmental problem in many areas due to strong short-term changes that do not take into account the long-term modifications that may appear.

Key words: Economic crisis, sustainable development, management, industrial tourism, rural tourism

J.E.L. classification: F02, F15

1. Introduction

Tourism is a blend between all the actions, activities, relationships and phenomena caused by the movement and the stay of persons outside their usual residence that should not be motivated by a lucrative activity, permanent or temporary [2].

Currently there is a change in the tourism industry. Issues such as quality, flexibility, awareness about environmental issues and individualization become more important everyday.

Rural tourism is a main sector of the Romanian tourism today and that requires an inclusive and credible strategy in the overall strategy plan of the Romanian tourism and also an association with other local and regional development projects which are developed by the Regional Development Agencies [4].

From the destruction of landscapes to ecological tourism, from concentration to avoidance of congestion, from the sun and

beach tourism to the contact with nature, from agitation to seeking tranquility.

2. The relationship between rural tourism and sustainable development

Sustainable tourism represents a development of the totality of forms of tourism, obtained through a good touristic management and marketing, that respects the integrity of the natural, social and economical environment, so that exploitation of natural and cultural resources to become beneficial for future generations.

The development of sustainable tourism takes into account the following aspects:

- The conservation of natural and human tourism resources for continuous use in the future;
- Developing the living standards for local communities;
- Better knowledge and awareness of local people and visitors regarding the idea of conservation.

The areas where sustainable the development planning process occurs are:

- The economical area, by increasing the exploitation and valorization of resources;
- The environmental area, by avoiding environmental degradation;

The connection between the rural tourism and the concept of sustainable development is relatively recent. In 1978, the United Nations Environment Program, it was highlighted that the environmental and economic problems are linked. If not too long ago the focus on developing tourism was solely economic, its objectives being considered a total success, recently the attention of specialists turned towards other

aspects relating to the socio - cultural impact on the local population, and also on the environment [3].

These new guidelines are components of sustainable development, thus a link is achieved between this new concepts and rural tourism.

Sustainable development responds to the present needs without damaging the chance for future generations to develop. The development of rural tourism is a way to ensure transmission of traditions to future generations, to not deprive the descendants of their identity.

Sustainable tourism can be defined as a form of developmental tourism that does not affect the conditions of existence of a certain area, enabling future generations of local people, and guests to enjoy these destinations further. It is a form of tourism that respects human beings, the environment and local culture of the host region and that brings an overall balance between the three dimensions (social, economic, natural), resulting in both improved quality of life that benefits all parties involved and also in economical profitability for local communities.

The rural tourism, in the perspective of sustainable development, is aimed towards other environmental problems, ie offering to future generations an environment as healthy as possible. This global problem is now becoming a topical issue. At the national level, actions and measures are needed in order to take into consideration the interests and concerns of all individuals with emphasis on the educational side and self-consciousness of each individual.

Rural tourism is a real hope for Romania. That is why this form of tourism has been reconsidered and redefined as an area of practice extended over the entire territory of the country. The form of organization of rural tourism was introduced also through commercial companies whose sole purpose are rural tourism activities. Currently, rural tourism has about 3% of the total touristic offer and will be supported to reach 5-10%.

3. E. U.'s decline in the tourism industry between 2008-2009 and the increasing interest in alternative forms of tourism

In September of 2009 revenue per available room in Europe presented a decrease of 19.2%. In the euro area a minus of 16.8% was recorded and in countries outside the euro area, the percentage was 21.9% (Table 1) [6].

Table 1. Evolution of revenue per available rooms in Europe

Regional performance rate (in euro)	Occupancy rate (%)	Average cost per room	Revenue per room on camera available room	Evolution income per available room (%)
Europe	61.6	94	58	-19.2
Euro areas	59.5	97	58	-16.8
Countries outside of the euro zone	63.5	92	58	-21.9

Source: <http://www.strglobal.com/>.

European tourism industry has undergone a hectic year in the context of the crisis becoming more deep. Rising unemployment, increasing the euro against other currencies have had a serious impact on the performance of specialized operators from Europe [1]. Many people chose to stay home rather than travel abroad, and the number of business travel was reduced, which has attracted the decrease in sales and also in the results of the hotel operators, airlines and travel agencies.

In this context, Romania has encountered in 2009 the most drastic decrease of all EU countries, occupancy rates of hotels in Romania reaching 57%.

In November 2009, compared to the previous year, both arrivals and overnight stays in tourist receptions with functions of accommodation, decreased by 15.8% and 17.9% (Table 2) [5].

Table 2. Arrivals and overnight stays in tourist receptions in November 2009 compared to November 2008

	Arrivals ^{*)}			Over-night ^{*)}	
	November 2008 - Thousands	November 2009 - Thousands	November 2009 Compared to November 2008 - %-	November 2008 - thousands	November 2009 - thousands
Total	495,5	417,4	84,2	1403,6	1153,7
Romanian tourists	405,1	327,6	80,9	1196,4	970,2
Foreign tourists	90,4	89,8	99,3	207,2	183,5

*) In the establishments of tourist reception

Source: INSEE, no. 11/2009

Our research revealed three groups of possible causes of the decline in Romania:

a) Tariffs

The crisis made the hotel rooms in Bucharest less expensive, almost 20% in 2009, the average price of accommodation is 81.43 EUR in November comparing to 100.61 EUR in November 2008. But the decline was modest compared to countries with important traditions in tourism resulting in lower revenues per available room whit 12.7% on average in 2009, compared to 2008's average.

b) The decrease of purchasing power

According to data from May 2008 from the National Institute of Statistics [7], the net average wage per economy was in March 1192 lei, increasing by 5.1% from the previous month. But both the amount and its dynamics in recent months show that in the first quarter, purchasing power has eroded significantly, due to the rises recorded in the same period.

In January, the wages compared to December [8] were showing 5.2%, then in February than in January, 5.5%. There was an increase of 5.1% in March, resulting in reduction of overall revenue in the period from January to March, 5.6%. On the other hand, however, prices have risen continuously, with 0.86% in January, then

0.7% in February and 0.67% in March, thus means a rise of 2.23% during the analyzed period of time. If we compare this to the earnings, we size the erosion of purchasing power in the first quarter: the gap between the plus and minus the price gains as almost 8%.

c) International Terrorism

By its nature, tourism is a highly competitive global industry. In this context, the lack of safety and security and the incidence of crime is a more serious threat to tourism and travel than any other negative factor.

4. Key factors for a sustainable tourism strategy

The key factors for a sustainable tourism strategy in rural protected areas, include:

Working with Rurality: the uniqueness and the special nature of the market niche of rural tourism is the rurality itself, the contact with nature, the traditional rural society, animal breeding, with forests or fishing communities. Sustainable tourism should not only be located in the country but it should be a part of a functional rural society and not a tourist resort located on a former farm.

Diversification not replacement: The goal of sustainable tourism should be diversifying the local economy and not replacing farming activities with tourism activities. Substitution would have three dangerous effects: the addiction concentrated to a sole activity, causing the start of resort-type development and thus losing its uniqueness based on ruralism and nature, thus beginning the decline of agriculture leading to the destruction of landscapes and habitats. The loss of traditional landscapes and habitats is the default loss of uniqueness and of the market niche (unique selling point) for tourism, causing irreparable loss of cultural and natural values.

Tourism as a Tool: Tourism can be developed in two ways. Tourism can be developed only for itself and it is possible that this process will bring jobs and prosperity in the area or can be viewed in a broader context and used as a tool to solve or mitigate certain specific problems. For example, accommodations can be developed as hotels belonging to various national and international hotel chains. These networks,

that already have the existing marketing and management facilities, can be successful and create jobs in rural areas. The concepts of sustainable tourism development suggests an alternative: If the local owners of tourist facilities would be developed following the restoration of traditional houses or new buildings, would create a number of additional advantages. First of all residents would be strongly motivated to remain in the area and to maintain traditional activities. Locals would thus increase their horizon, acquiring skills and knowledge they will need training, which is beneficial for the diversification of the activities. The community also has an interest in renovating existing buildings rather than build new ones that would probably not fit into the context of existing areas. Profit resulting from tourism will remain in the community. The concept of tourism as a tool can be used for natural conservation in protected areas, revitalization of rural rail services, increasing revenues in the retail markets for functional preservation of other types of services provided by local communities.

Conservation: The need to conserve natural habitats and host communities is crucial to the concept of sustainable rural tourism. While some types of tourism can destroy communities and habitats, sustainable tourism aims to use income and opportunities of tourism activities as a tool for conservation. For example, revenue from the millions of tourists worldwide who practice bird watching can be used to help preserve the specific habitats that would otherwise be used for agriculture or intensive deforestation. Income from the sale of food and non-traditional products can become similarly part of a conservation tools.

Empowerment and local control: The concept that control and tourism benefit should be to focus on local communities represents the essence of sustainable tourism. This can help to conserve local values, can make areas of declining revenues, may reactivate the political and social life in areas that have lost hope. Local control involves the formation of different skills, the successful development always involving training, continuing education and community information from and to his members.

Diversifying the economy: while tourism may seem to many rural communities and their leaders as the panacea to their problems, there are big threats related to development of tourism as the sole source of economic activity. Tourism is a competitive industry with a "fashion" that can change very quickly. Rural communities may face serious problems if they only rely heavily on the tourist market. In order for tourism to remain a rural one, an authentic economy should be encouraged, one with prosperous farmers, with a rural life and on a cultural authentic and original scene.

Marketing: There is a trend towards marketing not being considered important enough on the priority list when designing strategies for environmentally friendly tourism. However, in the cases of sustainable rural tourism strategies, effective marketing is vital. It is an activity requiring a high professional expertise without which the whole strategy can fail. A key element is constituted by specific market niches that take into account specific attributes of protected areas.

5. Conclusions

In the concept of sustainable tourism activities not only planning and tourism development are included, but also tourism fits into a balanced relationship that includes future development in the context of achieving conservational goals. Asserting and maintaining a brand image for the services requires a balance between supply-side report, service quality and perceived price, which must be protected against financial abuse and professional negligence.

Each type of private rural location offers opportunities and poses specific problems. Therefore, the tourism product offered should be prepared exactly according to the presence of various components in relation to the individual character of the settlement. Romania can meet the most demanding tastes and preferences of Romanian and foreign tourists.

The Seniority Principle and the Conversion Principle in the Defense of the Community Trademark

Abstract

The existence of an international registration system of marks and the creation of a Community trade mark allows a holder to receive a much wider protection from a geographical scope. Harmonization in the context of trade marks is desirable, as it provides the skeleton on which trade marks holders can plan their marketing strategy, while being sure that their trade marks can be protected in different countries in an identical or similar way.

The European Union is an area in which suppliers of goods and services can benefit from a unique protection within all Member States.

Key words: Seniority Principle; Conversion Principle; Community Trademark; intellectual property.

J.E.L. classification: K11

1. Introduction

Compared to the known trade mark protection systems - the national system and the Madrid system – the Community trade mark system brings two new principles, namely: - the principle of seniority and the principle of conversion (transformation), a feature in itself known as being introduced in the international protection system by the Protocol on the Madrid Settlement.

The holder of a Community trade mark, which is identical to one obtained by means of a national or international registration, will be able to claim the seniority of the respective trademark, according to the so-

called principle of seniority, whose main effect is the following: when the claimed and accepted national registration lapses, in order to maintain the rights granted by protection, it will not be renewed [1].

2. The Seniority Principle

The term "seniority" adopted within the area of the Community trade mark has the same meaning in English and French [2].

According to articles 34 and 35 of Council Regulation 40/94, the applicant or proprietor of a trade mark may claim the seniority of a national trade mark previously registered in a Member State or a previous international registration having effects in a Member State.

The claiming of seniority may be made:

- with the Community trade mark registration application or
- within two months from the registration of the Community trade mark application.

Also, the seniority claim of a previously registered national mark may also be made after the registration of a Community trade mark.

The seniority of a national or international trade mark may be claimed when filing the application, within two months, or any time after the trademark registration.

The applicant or the holder of a trade mark may appeal to the seniority of a trademark registered in a Member State.

2.1. The unitary nature of the Community trade mark

The community trade mark has a unitary nature and produces valid effects throughout the European Union, granting the holder an exclusive right to prevent third parties to use the sign registered as a Community trade mark in commercial or industrial activities across the Union; the Community trade mark will coexist (or should coexist) with the national trade marks in Member States; by means of accession treaties, the previously registered Community trade marks shall automatically extend its effects in all states joining the Union.

2.2. Coexistence

The community trade mark does not exclude the other registration systems of trade marks; the Community trade mark registration system coexists with the national registration system and also with the international registration system of trade marks, an applicant being able to choose the most convenient registration system, depending on its economic and financial interests and not only; according to this feature - or as a consequence of it - under certain conditions, the Community trade mark may be converted into a national trade mark and the national trade mark may be transformed in a community trade mark.

2.3. Transforming the Community trade mark application in a National trademark

The applicant for a Community trade mark application, where it could not be registered, is able to transform the Community trade mark application in a national application in those States where there is no a barrier regarding its registration, benefiting from the date of filing the community trade mark application; the same right is also granted to the holder of a registered Community trade mark which is no longer effective in one or more member States.

2.4. Seniority Effects

The only effect of invoking seniority is as follows: if the Community trade mark holder renounces to the previous national mark, or from some reason it (the national brand) ceases to "live", the owner benefits from the same effects as if the previous national mark would be still registered.

2.5 Seniority Claim

In order to claim the seniority of a previous national mark, the latter must be identical to the Community trade mark for identical goods and / or services (or which are contained in the list of products belonging to the previous national trade mark).

The benefit of a possible claimed and accepted seniority is that it preserves the advantages offered by the investment and advertising campaigns conducted previously, in the countries where the original registrations subject to seniority are in force.

2.6. The seniority claim application

The seniority claim application shall be submitted to the OHIM, with the Community trade mark application or within two months after filing the Community trade mark application. The same seniority claim application shall be submitted to the OHIM if the holder of an already registered Community trademark wishes to do so at any time during the Community trade mark protection, according to the interests of its owner. A seniority claim application for one or more previously registered trade marks under Articles 34 and 35 of the Regulation includes:

- the registration number of the Community trade mark application or of the community trade mark, if applicable;
- name and address of the applicant or of the Community trade mark holder;
- professional name and address of the trustee, if applicable;
- the name of the Member State or States in which the previous mark is registered, the date on which the registration entered into force, and the products and services for which the

Community trade mark registration was applied for or the registered Community trade mark products and services;

- specification of products or services for which seniority is claimed;
- a copy of such registration, certified by the competent authority

2.7. Termination of the seniority effect

According to article 34, paragraph 3, and article 35, paragraph 2, of the Regulation, the seniority claimed for the Community trade mark terminates when the holder of the previous national mark, subject to seniority claim, is lapsed or when the mark is declared invalid or when it is given up to before the registration of the Community trade mark. The effects of seniority shall terminate if the substantial conditions (identity of the community and national trade mark holders, trade mark identity and identity - in whole or in part - of products and / or services contained in the two trademarks) are not met.

The effect of seniority ceases if the Community trade mark application is withdrawn, deemed to be withdrawn or denied, or if the Community trade mark ceases to have effects. In this situation, if seniority had not produced effects yet, the holder of the previous national mark can simply maintain the national mark with all the rights arising from holding it.

If the claimed seniority had already produced its effects, the Community trade mark and the rights relating to the national trademark are lost.

Currently, for a Romanian applicant for a Community trade mark, seniority may be established by a trade mark registered in one of the 27 EU Member States (registered by national means or by the Madrid system). Upon accession, the Romanian applicant may claim seniority also based on a previously registered national trade mark.

3. The Principle of conversion

The principle of conversion was introduced as a facility for international trade mark owners in the Protocol relating to the Madrid Settlement (art. 9 quinquies).

The Community trade mark Regulation (in article 108, paragraph 1) provides that:

- "the applicant or proprietor of a trade mark may request the conversion of the Community trade mark application or the registered Community trade mark in a national trade mark application producing effects in the Member States indicated in the conversion application starting with the date of the Community trade mark application or with the date of the registered Community trade mark, if the Community trade mark application has been refused, withdrawn or considered withdrawn or if the Community trade mark ceases to have effects".

In other words, if the Community trade mark application was refused on the basis of the objections issued by one or more national jurisdictions, the Community trade mark application registration can be converted in a national registration application in the Member States which did not object to the registration of the community trade mark, preserving its terms for these States, i.e. an eventual priority date and / or the seniority claimed in the Community trade mark application.

The transformation can not be done when:

- the Community trade mark proprietor has been lapsed for lack of use of the trade mark;
- for the protection in a Member State where, under the Decision of the National industrial property services, there is a reason for the refusal, revocation or invalidity of the Community trade mark application.

The national trade mark application resulting from the conversion of an application or of a registered Community trade mark shall enjoy, in the Member State concerned, at the priority date of that application or trade mark and, where appropriate, the seniority of a trade mark of that State claimed under Articles 34 and 35 of the Regulation.

The community trade mark application, which is accepted for protection in one or more EU countries, can be converted into national trade mark applications in the other EU countries where there are grounds for refusal, while retaining the priority date or the filing date of the initial community

trade mark application - the so-called "conversion procedure"[3].

The conversion procedure is triggered upon the presentation of the application to the OHIM, which takes into account the application presented only after the payment of conversion fee, which is 200 Euros.

The conversion application must be filed within three months from event related to the Community trade mark registration application or to the registered Community trade mark, which allows the formulation of such a conversion application (application for a community trade mark which was withdrawn or deemed withdrawn, definitively rejected by OHIM or as a result of a Decision of the National industrial property service, the Community trade mark ceases to have effect as a result of a final decision of the OHIM, the renunciation to the Community trade mark, the non-renewal of Community trade mark).

Exceeding the three months due date leads to failure to take into account the conversion application.

The conversion application of a Community trade mark application or of a registered Community trade mark in the national trade mark application must include:

- name and address of the applicant;
- professional name and address of the trustee, if applicable;
- the Community trade mark application number assigned and the registration number of the community trade mark;
- the date of the community trade mark application or of the registered Community trade mark and, where appropriate, information on priority and / or seniority;
- a representation of the mark as contained in the application or as registered;
- the Member State or States where the conversion is requested;
- identifying the goods and / or services - in whole or in part and differently from a state to state, if applicable;
- statements about the reasons that led to the conversion application (rejection, withdrawal, renunciation, non-renewal etc.) and the date of the event which caused this reason.

If all these conditions are met (listed in Art. 108 of the Regulation), the request for conversion is allowed and the OHIM immediately forwards it to the National Service of Industrial Property of the States mentioned in the application, including, if applicable, the Benelux Trade Mark Office, and it is published in the Community Trade Marks Bulletin. The OHIM communicates to the applicant the date of the transmission of the conversion application.

At the request of the National Service of Industrial Property from a State designated in the conversion application, the OHIM communicates any information which enables it to decide on the possibility of accepting the application for conversion. The National Service of Industrial Property of the designated State may not submit the conversion application in which it has been designated to different conditions from those provided in the Community Trademark Regulations and in the execution Regulations regarding the request.

4. Conclusions

To conclude with, we can say that there are three ways for the registration of trade marks, which provide a level of protection adapted to the business interests of companies. Thus, the nationally registered trade mark provides limited protection on the market of a single country, the internationally protected trade mark in particular solves the problem of extending such protection in the Member States of the Madrid Union [4] and the Community trade mark offers protection for the entire market within the European Community,

If a registration system is more advantageous than the other, everything is up to the companies interested both in terms of territorial protection, and of the actual costs.

The Community trade mark system is not restrictive; a community trade mark applicant or holder does not lose any previously held national right, under the condition of observing the terms, forms and payment of fees under the Community trade mark Regulation.

At present, a Romanian holder of the national mark registered in Romania is not able to rely on any right arising from ownership of the mark if he/she does not want to register an identical mark as a community trade mark; he/she may claim the seniority of an international trade mark right registered through the Madrid system, in one or more EU Member States.

The transformation of the Community trade mark application in national applications in countries that have not objected to the Community trade mark registration is allowed.

Since the accession of Romania to the EU, a Romanian applicant may claim the rights resulting from a trade mark registered in Romania.

Abstract

The phenomenon of current financial market globalization is accompanied by increasing manifestation of the risks related to operations in the financial market. Therefore it can be considered that capital adequacy to operational risk is a current research topic whose purpose is to evaluate its practical application. Basel provisions call for complex solutions through the development and use of advanced models by imposing capital adequacy requirements. From the moment the international financial crisis appeared, more and more obvious risks were recorded by credit institutions. These are the type of operational risk incident causing significant losses.

Key words: operational risk, basic indicator approach, standardized approach, advanced measurement approach, internal measurement approach.

J.E.L. classification.: C13, C81, D24

1. Introduction

Basel II proposes three methodologies for the measurement of own funds requirements for operational risk: basic indicator approach, the standard approach and an advanced approach. In Romania (NBR assessment on 10 November 2010), the manner of computing and reporting the operational risk capital requirements within the 33 credit institutions (the 10 branches do not report to the central bank capital requirements) was as follows: 27 credit institutions apply basic indicator approach, four credit institutions the

standardized approach and two credit institution apply advanced measurement approach. In this paper we use all three methodologies for a bank in Romania, the conclusion being that, unlike credit and market risk, which approaches are based on internal models and refer only to unexpected losses, operational risk for credit institutions should include both expected losses and unexpected losses. Information on operational risk losses have been divided into business lines and event types.

Basic Indicator Approach is the simplest of methods, and as its name says, this method is used to compute the capital requirements by using a single indicator of risk (i. e. the gross operating income). Banks using this approach must have its own funds to cover operational risk corresponding to a percentage of the average operating income recorded in the last three years. This flat rate risk, expressed by a capital adequacy ratio (denoted α) was set by the Basel Committee at 15%.

Standardized Approach is a redefinition of the basic approach - applying the same method for determining capital requirements – but the gross operating income is detailed in eight categories (business lines): corporate finance, trading and sales, payments and settlements, commercial banking, agent services, retail banking, retail brokerage, asset management. Gross income for each business line is considered as an indicator of exposure to operational risk. Equity requirement is determined separately for each category by applying a specific coefficient (denoted β) on gross income. β coefficients are between 12% and 18%. They approximate the relationship between

workload intensity in the line and losses generated by the event.

The third approach, the advanced approach allows banks to develop their own model for computing the capital requirement based on their internal estimates. To use this approach, banks must have the approval of the supervisory institution and must meet a number of conditions including to demonstrate that their methodology is sophisticated enough to capture the severe events, events that may occur with a probability of 0.1 % (or corresponding to a confidence level of 99.9%).

Unlike credit and market risk, which approaches are based on internal models and refer only to unexpected losses, operational risk institutions should include both expected losses and unexpected losses. Information on operational risk losses should be divided into business lines and event types of operational risk. Credit institutions have adopted a slightly advanced measurement approach. Even though the vast majority chooses the simplest method for computing the capital requirement for operational risk, banks in Romania are working to obtain approval to use the standardized approach, providing the premises transition to advanced approach, regarded as effective operational risk monitoring.

2. The Analysis

For the first pillar of Basel II on the minimum capital required to cover operational risk, financial institution, whose name Y will not be determined for reasons of confidentiality, has adopted an advanced model for measuring operational risk which aims to locate risk potential products and / or support activities, to estimate the potential impact.

In the analysis of the relevant financial institution concept is called "gross income" and to the design group is the sum of profit and loss of interest and similar income, income on commissions, income from financial operations, income from shares and other variable-income securities, and other operating income.

As the main business lines of credit institutions considered for the analysis of losses from operational risk: trading and sales, retail banking, commercial banking

and other activities (which includes overlapping corporate financing activities, payment and settlement services as agent) , classification of operations performed on the basis of specific criteria and policies developed and implemented in internal procedures.

For the all business lines analyzed the financial institution used as an indicator the "gross income", considering it as the Basel Committee recommends a clear indicator present in annual financial statements, on which the calculations can be easily done and national and international comparisons are easily audited and reflecting good operational risk sensitivity.

To determine the capital requirements for operational risk under the basic approach is was applied the factor 15% of average gross income received by each credit institution over three consecutive years.

Where the standard model for determining the capital requirement should be started the process of allocating gross income for each business line as can be seen from Figure no. 1, the average gross income for each business line will apply the appropriate risk weight (between 12% and 18%) to calculate the capital requirement.

Obtaining high values for a particular business line shows the size and intensity of activity gross income of the institution concerned on those industries. It also provides information about the departments concerned with potential losses that may occur and the amount necessary to cover losses related to operational risk business lines.

Figure 1 Capital requirement under the standardized approach to business lines of credit institution Y

Source: author's computation

Looking at Figure 1 we can conclude that the most risky lines of business are commercial and retail banking business, which are mainly due to trading and processing errors that may occur with the activities of the bank; errors cashier activity; errors occurring at the time of payment,

errors occurring in the exchange rate, systems malfunction; fraud, garnishment making error, errors in the administration of claims.

Losses arising from operational risk, credit institutions in Y, are identified and related international standards on the seven types of events, such as internal fraud, external fraud, employment practices and workplace safety, clients, products and business practices; losses incurred tangible assets, business disruption and system failures and execution, delivery and management processes. Thus, on the basis of centralized documents by the accounting department, internal audit, IT, risk management, operations department, the Department of Operational Risk losses and the situation may types of events causing losses for the financial institution, which we present and new shown.

Figure 2: The probability of occurrence of events causing losses for the credit institution Y

Source: author's computation

If the credit institution Y most common losses were due to human error, then it is considered a risk of human resources related to the carrying out of unauthorized activities, due to negligence or deliberate form of unreported transactions, unauthorized, unregistered operations, reporting bad faith etc positions. The second place is occupied by business interruption and losses due to improper functioning of the systems. Also due to interruption of operations or errors in the system are risks related to the availability of hardware and software systems, data quality, problems of computer programs, failure of components, problems related to telecommunications, software, design, implementation and maintenance of the system failure "e-banking, utilities, etc. overutilization.

Figure 3: Operational loss suffered by type of event for the credit institution

Source: author's computation

In terms of the severity of events a conspicuous place is occupied by the events occurring due execution, delivery and management processes. They are characterized by events such as: communications erroneous models or systems malfunction, improper maintenance of databases, errors in placing, operating, maintaining and updating data, or breach the terms of duties, lack of documents, loss, damage to customer property, outsourcing, partners, etc. controversy. category followed by customers, products and business practices, including losses due to: defective products, negligence, poor training or non-professionalism, selling products using aggressive strategies, compliance with rules of conduct or breach of trust, misuse of confidential information, erroneous analysis of needs customers, exceeding exposure limits, etc.

Then we use an advanced model, namely the Internal Assessment Approach (IMA), in order to calculate the capital requirement for operational risk.

The operational risk matrix established will consist of 16 cells, corresponding to four lines of business (trading and sales, retail banking, commercial banking and other activities) and four types of events (external fraud, internal fraud, Business disruption and system failures, execution, delivery and management processes).

Calculation of capital requirement under this approach will achieve the following steps:

a) for each business line should be determined average gross income, which I summarize in the following figure

Figure 4: Average gross income business lines

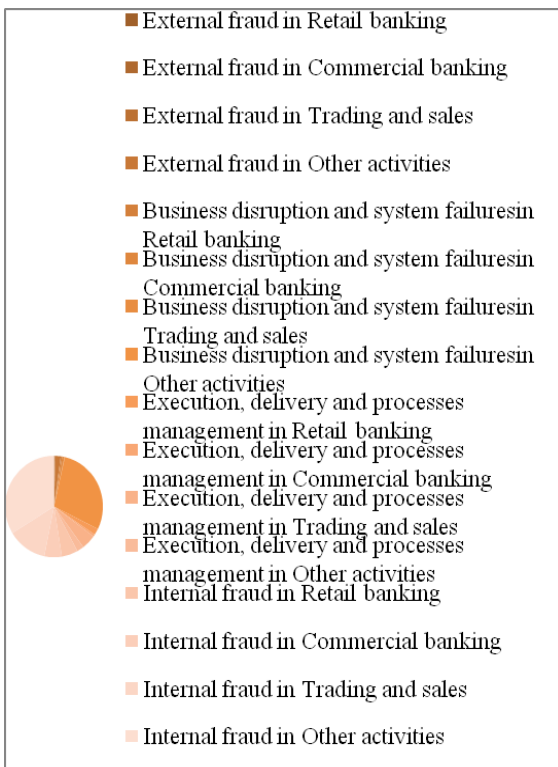

Source: author's computation

b) calculation parameters:

- Probability of Loss Event is used for internal historical data on the number of transactions with an operating loss and the total number of transactions per business line

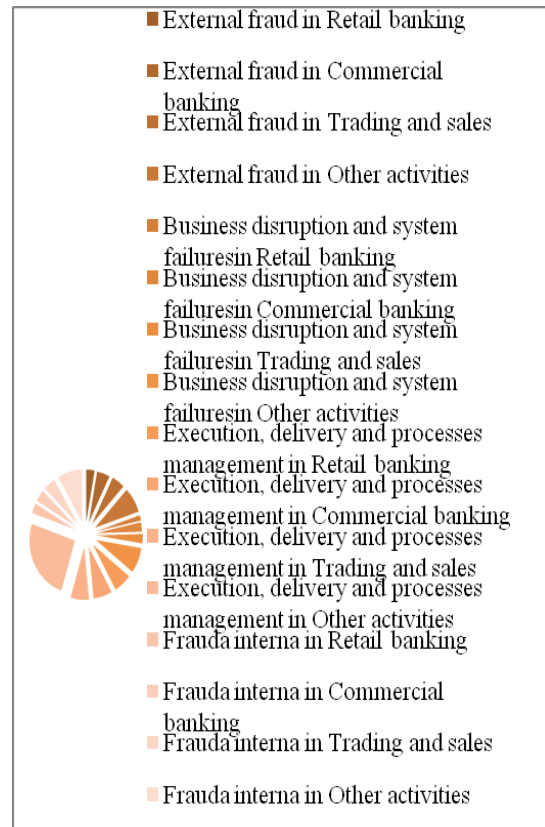

Figure 5: The probability of occurrence of events causing loss to each cell of the matrix of operational risk

Source: author's computation

- Loss of Given Event - proportion of exposure that should be recorded as operating loss

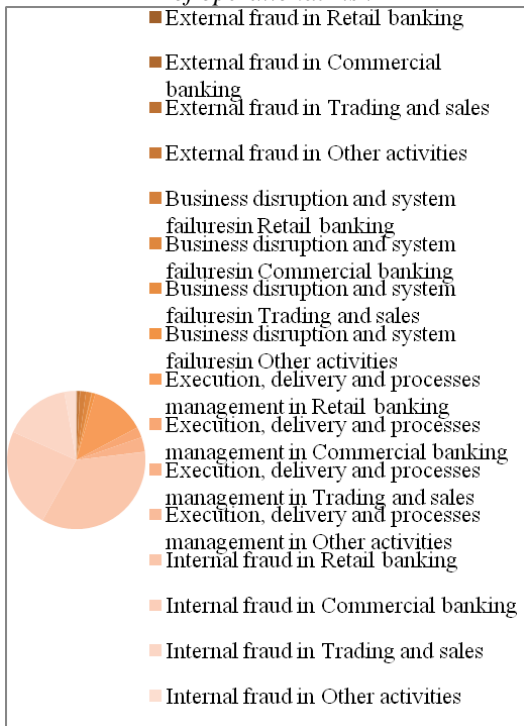

Figure 6: proportion of exposure that should be recorded as operating loss for each cell

Source: author's computation

c) Determination of the expected loss that occurred between the previously determined parameters and the average gross income.

Figure 7: Expected loss for each cell of the matrix of operational risk

Source: authors working

d) Determination of unexpected loss that occurred between the expected loss of the credit institution Y and the maximum loss for a period of one year and a confidence interval 99,9%.

Figure 8: Unexpected loss for each cell of the matrix of operational risk

Source: author's computation

Capital allocated by the credit institution is calculated as the sum of expected loss and unexpected loss for each cell of the matrix of operational risk for the latter institution, the bulk of capital for operational risk assessment approach led by Internal Affairs for distribution to the line for activities carried out by the credit institution with clients as business partners, a situation explained that this line of business is and better developed by this institute, and distribution of gross income.

Thus summing up the analysis for the credit institution Y, we can see, and Fig. 9, that once the bank uses a means of measuring the more complex operational risk, capital requirement for this risk is reduced. Thus the minimum capital mobilized using Internal Assessment Approach, because it can identify measure and manage operational risks more effectively being able to discover what business lines manifested a higher operational risk and who the most important risk factors are.

Figure 9: Capital requirement under the three approaches for the credit institution Y

Source: author's computation

3. Conclusions

In the literature, it is considered that the capital requirements for operational risk can be decreased by using more advanced methods, as demonstrated in the case of applying the basic indicator approach and standardized method, of data provided by financial institutions on which the analysis was performed. Decreased capital requirements are explained by the fact that if the Basic Indicator Approach assumes that capital requirements for operational risk is 15% of the gross income of the institution, in the Standardized Approach the risk level varies from one business line to another, and the main business line is the line for retail because the degree of risk is only 12%.

The credit institution has a clear and precise vision of the events causing the losses caused by operational risk and allocates capital based on the actual losses saving capital and retaining customers, thus providing a much better picture on the Romanian market.

By using advanced methods, credit institutions can identify the operations which cause operational losses and thereby demonstrate the progress made in the procedures of this type of risk management. But to use such methods, the supervisory authority must demonstrate that it has complete databases and well-documented, and in some cases must also have additional funds to be able to invest large sums of money in the operational risk assessment process. Setting the actual optimal level of capitalization for financial institutions is particularly important, because by allowing capital to meet the operational function of protection, which involves the absorption of losses for any contingencies that may arise during the course of business, will allow a decreasing of the probability of the bank's default rate and an increasing of the public confidence in the domestic banking system.

Abstract

This paper presents the issues related to the transfer of human resources management practices in Romanian companies. It is based on the results of several specialized studies. Romanian companies are looking for an improvement of their human resources management in order to remain competitive, especially in these difficult times. Transferring the most appropriate and efficient practices proves to be no easy task. There are many aspects that should be considered in the transfer process. It should be mentioned the limitations related to the institutional and legal framework, cultural dimensions of Romanian society etc. That limits will determine which practices are suitable for transfer and which will be rejected. It is also important to point out that in the past few years a more relaxed attitude was identified by specialized studies regarding the transfer process, leaving more space for new improved hrm practices. This trend represents an interesting lead for further research.

Key words: human resources management practices, transfer process, Romanian companies.

J.E.L. classification: M 12

1. Introduction

Human resources have become the most valuable assets of the modern organizations. The most dynamic and efficient companies found out that their personnel represents an important source for competitive advantages.

The Romanian companies are struggling to obtain and to maintain a level of efficiency that will allow them to survive within the actual economical background. An important step in this process should be represented by the necessity of develop a modern human resources management.

A modern approach of human resources management can be achieved by transferring modern practices that will allow the Romanian companies to become and stay competitive. This paper tries to analyze the different perspectives of such process based on the existing information supplied by different studies.

2. Theoretical approaches on human resources management practices transfer

The modern companies have to face constant and various changes within the actual economic background. These changes are reflected upon all functional field of an organization. The human resources domain makes no exception. In the same time, the human resources management within a company provides a great support for successful changes.

The process of European integration generated different debates among human resources management specialists about the convergence/divergence process of human resources practices [1].

There are many arguments for both theories. Convergence theorists sustain the idea that we can talk about an ongoing process of diminishing the differences between European countries based on the common institutional framework promoted across the European Union.

Divergence theory promotes the idea that noticeable differences exist between European countries (groups of countries are identified) based on specific institutional regulations, cultural dimensions etc.

Therefore, when a transfer process is brought into discussion those issues and specific approaches towards international human resources management practices are important matters to be considered.

The human resources management practices are analysed at the international level based on two major approaches [2]:

- **The rational approach** – the companies will develop the practices that will enable them to fulfil their objectives in a rational manner and efficiently. According to this point of view the managerial practices will be similar within a specific sector of activity for the same country, even for different countries. This approach assumes a high degree of managerial autonomy.
- **The institutional approach** assumes that the companies are influenced in a decisive manner by their environment. Thus, their practices will be adjusted considering the regulations and compulsions of this environment. Therefore the managerial practice will be different not only from a country to another, but from a sector of activity to another. These differences are explained by various elements such as different regulations concerning the business within a country, the relation between unions and management etc.

There are many issues that are related to the transfer of the human resources management practices. It is necessary to

establish in a clear manner what has to be transferred and what can be transferred, what elements can enable or jam the transfer process.

3. Human resources management practices within Romanian companies

In the past few years, the Romanian companies have assumed different principles, especially from the theory and practice of angle-saxon countries, regarding the human resources management practices.

In order to present the stage achieved by the human resources management within the Romanian organizations, a study undergone by Interact and Gallup Romania have revealed interesting results. This study tried to determine the main cultural values of our society, using the G. Hofstede methodology. Based on this, the most suitable approaches and practices of human resources management have been identified.

The most relevant results of this study are presented below [3]:

- **Human resources planning** due to the dimension of uncertainty avoidance, in the human resources planning process the human resources department has to analyze the job positions and to avoid the frequent changes within the organizational structure;
- **Recruitment and selection** in the recruitment and selection process the fact that the Romanian people are more compelling with the job satisfaction than the promotion opportunities or the stimulating side of job position has to be considered. The Romanian managers consider that the employee's loyalty is more important than the level of their performances;
- **Performance appraisal** the use of a system for the appraisal of the performances proves to be a difficult task. This is due to the fact that a clear statement of specific objectives and an enhanced attention paid to performance measurement generates anxiety among the subordinates;

- **Reward** for the Romanian employee the level of payment, the certitude at the work place, the working condition are more important than the job perspective or the content of job position;
- **Employee's training and development** the cultural dimension of collectivism determines that the employees are waiting for the company to provide them training and protection. The accent is based on complex and theoretical training. The employees seldom have initiatives toward action that will ensure a higher level of competency.
- The considerable degree of HRM transfer and adaptation to the globalization of the market lead to the use of HRM practices in Romanian companies.
- The subsidiaries have adapted their HRM practices to a considerable extent.
- Some practices are more localized than others. Specifically, practices that do not fit well with Romanian culture or are in contrast to employee regulations show a low level of transfer.
- The changing environment leads to the conclusion that there should be a constant research and evaluation of which practices are best suited to a specific socio-cultural context at a certain period.

The results of the above mentioned study indicates that the cultural context of our society represents an important issue that should be considered when the transfer process is developed especially by the multinational companies.

Another study regarding the Romanian employees revealed the following results [4]:

- ✓ The recruitment process is subjective and slightly formal;
- ✓ The selection is centralized and is often linked to friends and family members;
- ✓ Academic qualification is considered important but it is not always asked;
- ✓ The experience and references play a significant role when hire;
- ✓ The wages are connected with national wage level;
- ✓ The evaluation of performances is influenced by personal relations.

According to this study the human resources management practices reflects the cultural values of Romanian society.

4. Evidences concerning the transfer process

For the Romanian companies, the models offered by the multinational companies acting within our country, represent the most important source regarding the transfer issues.

The results of another study concerning the transfer of human resources management practices that involved local companies and multinational companies' subsidiaries pointed out the following conclusions [5]:

Another fact that should be considered when the transfer process is initiated is the legislative framework in our country. The last Labor Code promoted by the Romanian Government generates a more flexible legislative context for the companies in order to promote different human resources practices such as:

- Working time;
- Hiring and firing process;
- Reward and its connections with employee's performance etc.

Above mentioned facts indicates that the institutional theory regarding the transfer of human resources management practices is more suitable for Romanian companies.

The transfer process should consider the constraints of legal framework, cultural dimensions of Romanian society and other issues that will determine which practices are suitable for transfer and the ones that are not.

As we mentioned before an important role within this process is played by the legislative framework which can provide changes that will be perceived as compulsory by the companies and therefore accepted.

4. Conclusions

The Romanian companies need to constantly improve their management practices in order to stay competitive and survive in this difficult economical background. Considering the importance of human resources for the modern companies,

the specific practice should represent an important objective for them.

Transferring the most appropriate and efficient human resources management practices represents the solution for our companies.

Therefore, such a process proves to be no easy task. There are many issues to be considering when the transfer issue is discussed.

This paper aimed to present the main approaches related to the transfer issues at international level, considering the EU membership of our country. These approaches underline the main possibilities and also the potential difficulties related to that process.

The results of several specialized studies indicate that the Romanian companies have made important progress toward a modern human resources management in the past few years.

An important source for new human resources practice is represented by the multinational companies acting in Romania.

Although, there are important opportunities for our companies to transfer new practices it should be acknowledge the limitations regarding such process.

The results of specialized studies indicate that an institutional approach regarding the transfer process is the most appropriate for our country. In this situation there are several limits related to the institutional and legislative framework, the cultural dimensions of Romanian society etc.

Therefore, there are some practices that are more suitable to be transferred in Romanian companies, meanwhile others will be rejected.

Other studies confirm the above mentioned situations, but also indicate that it could be considered a change of perspective toward a more relaxed attitude. In this case we can argue that the possibility to transfer more new human resources management practices has increased. It could be an interesting field of work for further research.

Development of Exchange-Traded Derivatives Markets in Selective Central and Eastern European Countries

Anton Sorin Gabriel
Diaconășu Delia-Elena
"Alexandru Ioan Cuza" University of Iasi
sorin.anton@uaic.ro
delia_diaconasu@yahoo.com

Abstract

The transition economies of Central and Eastern Europe are trying to construct viable modern financial markets which provide a wide range of financial instruments. The paper focuses on the evolution of exchange-traded derivatives in Czech Republic, Hungary, Poland and Romania. The results indicate that the most developed exchange-traded derivatives market is the Polish one. In Hungary, the derivatives on currency rates and stock index futures are the most popular, while in Romania, trading takes place almost only in the market for futures on individual stocks. The use of derivatives in these countries is still limited even though some of these markets have registered a significant development. The main products have as underlying stock and currencies, while interest rate based instruments are still illiquid and underdeveloped.

Key words: stock exchange, derivatives, futures, Central and Eastern Europe.

J.E.L. classification: G13, G15, O16, O52.

1. Introduction

Along with globalization and liberalization of financial markets, there have been registered rapid changes in interest rates, exchange rates, prices of financial assets, thereby giving rise to increased financial risks. In this regard, an important role is taken by derivatives instruments to manage efficiently the risks caused by uncertainty and volatility of the underlying assets. Derivatives are risk management instruments that help a player in the financial market to

transfer the related risk. Such derivatives may be used for speculation, for hedging a portfolio of assets, for arbitration, and to structure the desired positions.

In this article we analyze the evolution of exchange-traded derivatives (ETD) in emerging markets in Central and Eastern Europe, by describing and analyzing statistical data. The analyzed states are members of the EU, but outside the euro area, namely: Czech Republic, Hungary, Poland and Romania. We use data on exchange-traded derivatives from individual emerging market exchanges.

2. Literature Review

In the literature there are numerous studies regarding derivatives markets in some countries or regions, on different time intervals and with different objectives. Ghysels and Seon (2005) analyzed the role of derivatives during the Asian financial crisis in Korea, showing that the market trades futures and foreign investors have played an important role during the 1997 stock market turmoil. Also, Baigent and Massaro (2009) examine the role of derivatives in the overstatement of prices and market corrections, making the link between the turmoil of 1987 and the 2007 crisis. First, they have demonstrated the existence of a stock bubble in 1987. Secondly, they have showed that the existence of derivatives and portfolio insurance is an explication for a market collapse, namely the idiosyncratic errors can lead to aggregation of the traders and an increase in leverage, both of which can cause prices supra evaluation. Hrovatin et al. (2009) pointed out that the financial derivatives contributed to the disruption of

financial system stability, with reference to the financial crisis started in 2007. References in this respect are: exponential growth derivatives in the last decade, increasing leverage and interconnection of financial institutions.

3. A Brief Review of Global Derivatives Markets

After several years of rapid growth, the development of derivatives markets has stopped and started a downward trend - with the exception of futures contracts on commodities - since 2008. In 2010, the global derivatives market has experienced substantial growth compared with the previous year. Year 2010 recorded a continuation of this growing trend in the regions of Asia-Pacific and South America (with 52.0% and 63.1%, respectively) and a resumption of the upward trend on the derivatives markets in Europe and North America (24.2% and 15.6%, respectively). Futures contracts have registered the highest growth rate of 47.0%, on one side, while derivatives on precious metals and currencies have increased mostly in this period (251.85% and 95.53%), on the other side.

Derivatives markets of Central and Eastern Europe are in an early stage and of a smaller size in comparison with the developed markets, like NYSE Euronext and Deutsche

Börse Group. The main products have as underlying stock and currencies, while interest rate based instruments are still illiquid and underdeveloped. The presence of substantial foreign exchange instruments is explained by the process of capital account liberalization and access to foreign investors in these markets. Although the derivatives turnover has increased considerably, especially in the Czech Republic, Poland and Hungary, both regulated and unregulated markets present a low liquidity. With regard to regulated markets, the derivatives are not traded in Bulgaria, but they will be introduced in the near future. Also in countries like the Czech Republic and Romania, derivatives were introduced relatively late in the stock exchanges, in 2006 and 2007 respectively. Finally, the greatest diversity of the stock exchange is the futures contracts, even if options contracts create more opportunities though they are more complex and costly and appeared relatively late. Thus, the options market is in an early stage in this region. It should be noted that on the Budapest Stock Exchange commodities futures contracts and options on commodities are traded, because BSE includes the Budapest Commodity Exchange. Table 1 gives an overview of the derivatives traded in CEE exchanges. Prague obtained the permission to organize derivatives trading in August 2001.

Table 1. CEE-5: Availability of Local Exchange-Traded Derivatives Instruments 2010

Source: World Federation of Exchanges

3.1. The Exchange-Traded Derivatives Market in Czech Republic

Prague Stock Exchange (PSE) began its development in 1995, with the liberalization of trading in the three markets, followed by several measures taken in 1998 within the financial system and implicit the derivatives

area. The main factors that led to the development of Czech derivatives markets are: active involvement of foreign banks on the capital market and the banking system concentration.

At Prague Stock Exchange derivatives trading began in 2006 through the licensing of new types of financial instruments (PX

index futures, warrants), thereby enabling access to these types of instruments to individual investors. At the end of 2010, stock and index futures contracts and stock options and index options were available for trading on the Exchange. The table 2 shows the evolution of the Czech exchange traded derivatives in terms of notional turnover and number of contracts traded.

Table 2. Derivatives market on PSE

	2007	2008	2009
Notional turnover (EURm)	67	28	8
Contracts traded	11,528	5,581	2,332

Sources: European Exchange Report 2007, 2008, 2009, www.fese.be

In 2007 the derivatives have registered a growing trend; the main contracts traded are the futures contracts, while the main category of underlying assets was the stock indices. The boom from 2006, since their introduction, was stopped on the Czech market in the year 2008, when the turnover dropped to more than half, because of the global financial crisis. The main reason for the decline of this segment was the distrust of investors that lowered the price of the underlying assets, increased the volatility and the withdrawal of foreign investors. This is provided that the latter had the largest share of total investors. In 2009 the downward trend has continued, the indicators of the PSE derivatives traded almost reached the value of 2006, the year of launching for these financial products.

3.2. The exchange-traded derivatives market in Hungary

Hungary was the first ex-socialist country that has reactivated the capital market. The first derivative, a currency futures contract, was launched in Budapest Commodity Exchange (BCE) in 1993. The Budapest Stock Exchange (BSE) derivatives market was launched in April 1995, when index futures on the BUX, the main stock index in Budapest, interest futures, and currency futures on the US Dollar, the Euro, the Japanese Yen, the British Pound and the

Swiss Franc were introduced to trading. The two regulated markets merged in 2005 and in present the derivatives are traded on the BSE. This integration leads to an increased development. Derivatives are an important part of the BSE, the main derivatives traded being foreign exchange contracts followed by stock derivatives.

Table 3 presents the evolution of derivatives traded on Budapest Stock Exchange. The BSE derivatives market turnover rose by 116% and hits the turnover of the spot market in 2005.

In 2006, the total value of deals was 24,357, the most consistent growth of about 50% was made by currency futures. This is due to the high volatility of forint. The growing demand for currency derivatives is driven mainly by three factors. Firstly, it is supported by foreign exchange regime applied by Hungary which is characterised by a 30% wide fluctuation band, reason why currency risk is taken into account by traders and hedgers. Secondly, the increasing trading volumes of currency derivatives are the consequence of decision of Hungarian Financial Supervisory Authority which in 2003 permitted trading on cross rates derivatives. Not least, next few years the derivatives market was affected by the merger between Budapest Stock Exchange and Budapest Commodity Exchange, the result of which was the introduction on BSE of the contracts with one week settlement date and the influx of new investors.

In 2007 the accelerated growth ritm of futures contracts has stopped. The annual growth rate was only 8.6% and in addition, on some segments (like index futures), it has recorded a drop in the value of transactions. Like other derivatives market from CEE it can be distinguished an increase in the use of single stock futures, which shows an investors' appetite for speculations.

Beginning with 2008 the derivatives market started to fall as a result of the impact of financial crisis. The decrease of Hungarian derivatives market was bigger than in other analysed CEE derivatives market. This was due to the fact that the global crisis had a bigger impact on Hungary in a view for European emerging markets. This caused enormous fall on Hungarian currency – forint and on Hungarian Stock Exchange Stock

Index (had lost almost 30% in only two weeks). The Hungarian crisis situation is more complicated than in other countries (i.e. Poland or Austria), because it started in 2006 when the political impact was very big.

Traditionally, one of the most popular products of the BSE futures market was the BUX index contract, but the top has changed in the last two years. The currency market woke up from a long sleep by the end of 2002, and by 2003 there was an exponential upswing in the market. The most popular product was the HUF/EUR contract.

Table 3. Evolution of futures market in Hungary 2006-2009 (EURm)

	2006	2007	2008	2009
Currency futures	11,449	12,984	8.153,4	7.244,9
Single stock futures	7,137	9,899	5.073,0	3.853,6
Index futures	5,761	4,183	2.914,6	1.745,2
Interest rate futures	9,82	4,52	0,0	0,2
Total	24,357	26,471	16,141	12,844

Source: Budapest Stock Exchange, www.bse.hu

The success of the derivatives market on the Budapest Stock Exchange was due to the following factors: a boost on the foreign exchange markets that started in 2003, which could take place due to the increase in the volatility of the forint, on the one hand, and as a result of more advantageous taxation rules, on the other; the continuously widening product palette of the BSE, to which cross currency contracts were added in the autumn of 2002.

3.3. The Exchange-Traded Derivatives Market in Poland

The Warsaw Stock Exchange derivatives market was launched on January 16, 1998, when WIG20 index futures (the main stock index in Warsaw, covering the 20 largest and most liquid companies listed on the WSE) were introduced to trading. In the subsequent years, futures on currencies, individual stocks and other indices have followed.

Table 4 gives a summary of recent historical turnover volume for futures in Poland. In 2009, the volume of trading in futures on the WSE exceeded 13.9 million contracts, more than 10% up compared to the previous year. This put the WSE in fourth place among European exchanges (if the Euronext exchanges are counted as single institution) with regard to the volume of trading in the leading index futures contracts. High turnover on futures contracts is generated above all by individual investors, who in 2009 accounted for around 52% of trading volume in futures contracts and 65% in options. Domestic institutional investors were responsible for 37% of the futures trading volume and 31% of options trading, whereas foreign investors generated 11% of futures trading and 4% of options trading.

Table 4. Evolution of futures contracts indicators at Warsaw Stock Exchange in 2005-2009

	'05	'06	'07	'08	'09
Turnover value (PLN bil.)	238	377	662.8	606.8	509.1
Number of contracts *	54	48	41	40	37

*Note: number of contract at year-end.

Source: Warsaw Stock Exchange Fact Book 2002-2010, www.gpw.com.pl

Futures contracts are the most traded instruments in the WSE, the number and value of transactions is high compared to options. By 2008, the exchange traded derivatives have registered a rapid growth rate. The main reasons are the internationalization of the Polish stock exchange market, the fact that they signed a number of memorandum of cooperation with foreign exchanges, the presence of foreigners.

The next years so far brings new records for the WSE derivatives market and a promise of another successful year for this dynamic segment of the Warsaw Stock Exchange. The reintroducing of stock options and the launching of new currency contracts (GBP/PLN and CHF/PLN) in global crisis situation shows the strength of the derivatives segment from Polish Stock Exchange Market.

Since the launch of the WSE derivatives market, the WIG20 futures market has been the most dynamically developing segment in terms of trading volume. At the end of 2009, the future trading on the WIG20 reached a value of PLN 493,312 million. In contrast, the turnover value of futures contracts with a single underlying stock and currency futures is very low comparing to the trading volume in WIG20 futures, as table 8 shows. One reason for the rapid development of this contract is the fact that the nominal value of WIG20 is the contract size multiplied by 10 PLN, which is considered to be very low. So, this low value has attracted smaller investors to the market and, up to now, mainly the small traders have maintained the futures market liquidity.

The WIG20 futures is, in the same time, the most popular derivative instrument in Poland, and the most traded stock index futures of Central and Eastern Europe, ranking among the top five European stocks index futures. The high use of WIG20 stock index futures contracts in the context of increased volatility in the Polish capital market shows that Polish investors use these tools in order to cover market risk. Despite the impact of the financial crisis, the popularity of WIG20 futures contract did not suffer at all.

Also, on this market, options are being traded. At the end of 2009 from a total of 110 series of options traded, all of them were WIG20 options. The trading volume for these instruments reached nearly 422,000 items, nearly 30% up versus 2008.

Financial and commodity derivatives are also traded on the Warsaw Commodity Exchange, the most popular traded derivatives being currency derivatives. However, none of the derivatives listed on Warsaw Comodity Exchange is so liquid as the WIG20 futures contract. In addition, the most liquid are those based on EUR/PLN and USD/PLN exchange rates.

3.3. The Exchange-Traded Derivatives Market in Romania

Derivatives market in Romania is composed of: Sibiu Monetary Financial and Commodities Exchange (SMFCE) and Bucharest Stock Exchange (BSE). The

beginning of these instruments is placed in 1997 by the launch of a futures contract BMFMS BMS1. In subsequent years, futures and options on futures on currencies (ROL/USD, ROL/EUR and EUR/USD), cross rates, stock index, interest rate (BUBOR3) were available for trading on the exchange. The evolution of financial derivatives traded at Sibex are presented in table 5.

Table 5. The Dimensions of derivatives market from SMFCE

	Number of futures contracts	Number of options contracts	Total contracts
2005	696,109	11,629	707,738
2006	4,232,059	36,651	4,268,710
2007	3,456,023	34,900	3,490,923
2008	3,578,582	40,184	3,618,766
2009	2,430,849	52,438	2,483,287
2010	1,620,078	17,716	1,637,794

Source:

<http://www.sibex.ro/index.php?q=fu&a=st&lang=ro>

At SMFCE the volume of traded derivatives had an accelerated growth since 2005, due to the volatilities of shares. By far the most commonly traded derivatives at the SMFCE were in 2004 the futures on currency rate, which held over 86% of the total trading contracts. In 2005 the transactions with currency futures accounted only 5% (35,813 contracts) of the total trading contracts, while single stock futures have faced a real boom regarding the volume of trading reaching 95% (660,296) of the total trading volume. This change in investors' preference was due to many factors: the shares' bulge in the first two months of the year 2005, the relative stability of the exchange rate of the main currencies, the possibility to protect the stock portfolio against the down trend, which followed the January-February market boom. The increased liquidity of derivatives stock in 2005 is the result of the investors' interest in only six contracts that have counted 95% of total transactions: DERRC, DETLV, DESIF2, DESIF3, DESIF5, and DESNP. In 2006 stands out an increase in the volume of transactions in futures contracts by 900% and starting with 2007 this value began to decline

as a result to the effects of the financial crisis, which is present on the Romanian capital market. However, even if stock futures fell in 2008 the currency futures based on EUR/RON grew with 500% because of the increased price volatility of Euro.

The share of options in total contracts traded stands at the value of 1%. This fact is due to the simplicity of futures' mechanism compared with the options' mechanism.

At BSE the futures trading was launched in 2007 and the activity on derivatives market is very modest. The listed derivatives are futures that have underlying indices, stock and currencies. The activity on this market was restricted until 2009, when it was introduced the market maker activity on EUR/RON contract. So, the volume of currency futures based on EUR/RON grew because of the increased price volatility of Euro. The interest for derivatives products traded on BSE increases as more and more products are launched. So, the increase trend of derivatives in 2010 was due to the launch of structured products in July.

Compared with other exchanges, however, the number of derivatives contracts is relatively small and the offer is limited and not least unlike other developed markets, the largest industry is represented by futures, other segments being poorly developed.

4. Conclusions

While in Bulgaria there is no exchange for financial derivatives, in the other countries the derivatives market are in different stage of development. In Poland, the market for stock index future is the most active in terms of trading volume. In Hungary, the derivatives on currency rates and stock index futures are the most popular, while in Romania, trading takes place almost only in the market for futures on individual stocks. As an important segment of capital markets, the development of the derivatives markets will bring more investors in the emerging countries, higher market liquidity and efficient risk management instruments. Furthermore, a developed derivatives market represents a step of the integration into the European capital market.

Economic and Accounting Issues Regarding Business Combination

Asaloş Nicoleta

Georgescu Cristina Elena

„Ovidius” University of Constanta, Faculty of Economic Sciences

nicoleta_asalos@yahoo.com

Abstract

Some businesses units do not survive the competition and finally close the business. Hence the excessive competition became a very powerful cause of business combination. Elimination of competition means creating monopoly in the market. Adopting IFRS 3 was to improve the relevance, reliability and comparability of the information that a reporting entity provides in its financial statements about a business combination and its effects.

Key words: business combination, fair value, intangible asset, goodwill

J.E.L. classification: M41

1. Introduction

In the earlier stage of business firms there was no strong competition among the business units due to small scale and direct contact between the producer and consumer. Now a day there is stiff competition among the business units due to expansion in the market. The stiff competition among the business units has increased the capital risk and lowered the profits of the firms. Often, the firms do not survive the competition and finally close the business. Hence business units combine together in order to enjoy the benefits of monopoly, like high profits. Ups and downs occur at regular intervals in the capitalistic economy. It consists of booms and depressions. It leads towards the combination of many business units. In the period of boom business units combine with each other in order to enjoy maximum benefits, because each economic indicator is going in positive direction, while during the tenor of depression business units combined with each other for their survival, because

each economic indicator is going in negative direction.

2. Economic issues Regarding Why Business Combination

A **business combination** occurs when one corporation obtains *control* of a group of *net assets* that constitutes a *going concern*. A key word is *control*—**control** can be obtained either by: 1. buying the assets themselves (which automatically gives control to the buyer), or 2. buying *control* over the corporation that owns the assets (which makes the purchased corporation a subsidiary).

A company may expand in several ways. Some firms concentrate on **internal** expansion. A firm may expand internally by engaging in product research and development. Hewlett-Packard is an example of a company that relied for many years on new product development to maintain and expand its market share. A firm may choose instead to emphasize marketing and promotional activities to obtain a greater share of a given market. Although such efforts usually do not expand the total market, they may redistribute that market by increasing the company's share of it. For other firms **external** expansion is the goal; that is, they try to expand by acquiring one or more other firms. This form of expansion, aimed at producing relatively rapid growth, has exploded in frequency and magnitude in recent years.

Any company may achieve significant cost savings as a result of external expansion, perhaps by acquiring one of its major suppliers. In addition to rapid expansion, the business combination method, or external expansion, has several other potential advantages over internal expansion:

1. **Operating synergies** may take a variety of forms. Whether the merger is **vertical** (a merger between a supplier and a customer) or **horizontal** (a merger between competitors), combination with an existing company provides management of the acquiring company with an established operating unit with its own experienced personnel, regular suppliers, productive facilities, and distribution channels. In the case of vertical mergers, synergies may result from the elimination of certain costs related to negotiation, bargaining, and coordination between the parties. In the case of a horizontal merger, potential synergies include the combination of sales forces, facilities, outlets, and so on, and the elimination of unnecessary duplication in costs. When a private company is acquired, a plus may be the potential to eliminate not only duplication in costs but also unnecessary costs.

2. Combination may enable a company to compete more effectively in the **international marketplace**. For example, an acquiring firm may diversify its operations rather rapidly by entering new markets; alternatively it may need to ensure its sources of supply or market outlets. Entry into new markets may also be undertaken to obtain cost savings realized by smoothing cyclical operations. Diminishing savings from cost-cutting within individual companies makes combination more appealing.

3. Business combinations are sometimes entered into to take advantage of **income tax** laws. The opportunity to file a consolidated tax return may allow profitable corporations' tax liability to be reduced by the losses of unprofitable affiliates. When an acquisition is financed using debt, the interest payments are tax deductible, creating a **financial synergy** or "tax gain." Many combinations in the past were planned to obtain the advantage of significant operating loss carryforwards that could be utilized by the acquiring company.

4. **Diversification** resulting from a merger offers a number of advantages, including increased flexibility, an internal capital market, an increase in the firm's debt capacity, more protection from competitors over proprietary information, and sometimes a more effective utilization of the organization's resources.

Combination accounting has long been controversial because of divergent views on how to provide the most useful information. In addition, many implementation problems arise from specific and often unique features of individual combinations. The accounting profession's struggles with these challenges are reflected in diverse and often inconsistent practices. Debate has swirled around goodwill and other intangibles. Minority interests have also been reported in several ways. These inconsistencies diminished the usefulness of the information to the point that new standards were needed.

3. Implementation of IFRS 3 Business Combination

IFRS3 was designed to improve the transparency of acquisition accounting, an area where a lot of accounting manipulation has occurred in the past. IFRS 3 requires in essence, that all assets on an acquisition, both tangible and intangible, be restated at their market values when accounting for the acquisition. The key implications on financial statements from IFRS3 Profit and loss account – goodwill and intangibles are: there will no longer be a charge for the amortisation of goodwill. This is useful as such charges were often previously disregarded; there will be charges for the amortisation of intangible assets which have finite estimated lives. As the values of such assets could be based on the present value of future profits their amortisation will be effectively eliminating those profits as they occur after acquisition. In extreme cases it could mean that little or no profits are reported for many years after the acquisition, a highly contentious area; there could be charges for impairment where the carrying value of intangible assets is higher than its value. These might occur through a change in strategy, or they might reflect badly on management. Impairment charges will be a highly sensitive area. The implications from IFRS 3 Balance sheet – goodwill and intangibles are: goodwill brought forward at the date of adoption of IFRS (which will often be significant) will be frozen at its brought value. So this figure will be stated at historic goodwill at the dates of pre IFRS3 acquisitions (including IFRS3 intangible values not required pre IFRS3), less pre

IFRS3 amortisation, plus post IFRS3 goodwill at the dates of acquisitions and less impairment charges. This is such a complicated combination of concepts that the figures given will most likely be impossible to understand; some intangible assets will be stated at their historic valuations, and some intangible asset values will be after charges for amortisation and impairment; values of goodwill and intangible assets are stated at historic amounts and not revalued; goodwill and intangible assets which have not been acquired will not be shown.

According with the recent amendments the objective of IFRS 3 is to improve the relevance, reliability and comparability of the information that a reporting entity provides in its financial statements about a business combination and its effects. To accomplish that, principles and requirements are established for how the acquirer: 1. recognizes and measures in its financial statements the identifiable assets acquired, the liabilities assumed and any non-controlling interest in the acquire; 2. recognizes and measures the goodwill acquired in the business combination or a gain from a bargain purchase; and 3. determines what information to disclose to enable users of the financial statements to evaluate the nature and financial effects of the business combination.

Also the IASB has determined that Costs incurred in an acquisition are period costs. Costs of issuing debt or equity instruments are accounted for under IAS 39 Financial Instruments: Recognition and Measurement. All other costs associated with the acquisition must be expensed, including reimbursements to acquire for bearing some of the acquisition costs.

Some of the most significant changes are in relation to the purchase consideration. Consideration now includes the fair value of all interests that the acquirer may have held previously in the acquired business. This includes any interest in an associate or joint venture or other equity interests of the acquired business. Any previous stake is seen as being 'given up' to acquire the entity and a gain or loss is recorded on its disposal. If the acquirer already held an interest in the acquired entity before acquisition, the standard requires the existing stake to be re-measured to fair value at the date of

acquisition, taking any movement to the income statement together with any gains previously recorded in equity that relate to the existing holding. If the value of the stake has increased, there will be a gain recognized in the statement of comprehensive income (income statement) of the acquirer at the date of the business combination. A loss would only occur if the existing interest has a book value in excess of the proportion of the fair value of the business obtained and no impairment had been recorded previously. This loss situation is expected to occur infrequently.

4. A short view between UKGAAP reviews and IFRS 3 about intangible assets, fair value of stocks and goodwill

UKGAAP requires recognition of an intangible asset of an acquired entity only if its fair value can be reliably measured. In practice, this meant that few intangibles are valued and reported on the balance sheet. IFRS3 requires recognition if the asset is identifiable; that is if it is separable or arises from contractual or other legal rights. In this context, separable means that the asset can be separated from the rest of the entity and sold, licensed, rented or transferred. While the requirement for reliable measurement is still present, IAS 38, Intangible Assets, assumes that this will be possible, stating that: *The fair value of intangible assets acquired in business combinations can normally be measured with sufficient reliability to be recognised separately from goodwill.*

As a consequence of the strengthened requirement to recognise intangible assets, more intangibles are being recognised within business combinations and this trend is likely to continue as companies and auditors become more familiar with the process. Published accounts in the United States in the years following the introduction of SFAS 141 (the US accounting standard equivalent to IFRS3), have shown increases in the percentage of purchase price allocated to intangibles within market sectors, but the progress has been fairly glacial and goodwill remains the dominant component.

Methods of valuation of intangibles are a subject on their own, but suffice it to say that there are a number of well understood techniques with most reliance being placed on the relief from royalty method. One practical area of difficulty is where intangible assets overlap, for instance brands and customer relationships. Care is needed to ensure that fair values are separated and not double counted, and the commercial realities of the market in which the entity trades must be considered. For instance, in a consumer products business such as wines and spirits, broad distribution and good customer relationships are key to success, but these will ultimately be worth little when there is a strong portfolio of brands. Most of the intangible asset value rests with the brands. In addition to any amortisation, it is necessary to review annually the value of intangibles for any impairment. If the present value of future anticipated cash flows is lower than the book value, that value must be written down to the impaired value. If, in future years, the value of future cash flows increases again, the write down can be reversed.

Whereas UK GAAP requires stocks acquired as part of a business combination to be valued at the lower of replacement cost and realisable value, IFRS 3 defines fair value as selling price less the costs of disposal and a reasonable margin for selling effort. For high margin consumer goods this raises questions about how the margin is divided between the activities of production and selling, and ownership of the brand. Again great care is needed to ensure that fair value already attributed to the brand is not double counted by overstating the fair value of stock. Even finished goods in their branded packaging do not command the full selling price without the brand owner's approval. Sales of genuine product through unofficial channels achieve substantially lower prices than the same product sold through legitimate sales channels. Much of the value still attaches to the brand and should not be included in the revaluation of stock.

Under UK GAAP, goodwill is presumed to have a useful life not exceeding twenty years and is amortised over that period. Under IFRS 3, amortisation is not permitted and existing partially amortised goodwill is

frozen at its net amount at the date of transition. Impairment testing of goodwill is already a requirement under UK GAAP, if circumstances indicate that the carrying value may not be recoverable. In practice, this happens rarely because amortisation steadily reduces the carrying value. Under IFRS, however, goodwill impairment becomes a much bigger issue and tests have to be carried out annually. Any impairment of goodwill is deemed to be permanent and cannot be reversed in the future. As goodwill does not generate cash flows directly, it must be assigned to a cash generating unit and it is the total value of all the assets, including goodwill, of the cash generating unit (CGU) that is compared to the value of future cash flows. In the event of a shortfall, the goodwill is reduced in value by a charge to profit.

Defining cash generating units as broadly as possible, will minimise the risk of embarrassing goodwill impairment. The broadest level allowable under the standard is that of reporting segment and the acid test is whether the proposed CGU generates largely independent cash flows. If it can be argued that the cash flows within a segment are inter-related, for instance if the segment comprises vertically production and sales and distribution units, it should be possible to assign goodwill at the segment level.

5. Conclusions

All business combinations must be accounted for using the acquisition accounting method. IFRS3 was designed to improve the transparency of acquisition accounting and requires in essence, that all assets on an acquisition, both tangible and intangible, be restated at their market values when accounting for the acquisition.

A further consequence of IFRS 3 is that intangible assets must be recognized separately from purchased goodwill instead of being subsumed within purchased goodwill. Purchased goodwill itself is not amortized, but must be reviewed for impairment annually. The performance of the impairment review is covered by IAS 36, Impairment of Assets, and the identification and recognition of intangible assets is covered by IAS 38, Intangible Assets.

The following steps are involved in accounting for a business combination under IFRS 3: 1. identification of the acquirer and the acquiree; 2. performance of a fair value exercise on the acquiree's assets and liabilities; 3. identification and measurement of the fair value of the intangible assets arising; 4. measurement of the amount of any non-controlling interest in the acquiree; 5. measurement of the amount of goodwill arising from the transaction.

The Importance of the Service Delivery Process in Achieving High Customer Satisfaction in Banking Services Industry

Asandei Mihaela
Micuda Dan

"Constantin Brancoveanu" University of Pitesti
mihaela.asandei@univcb.ro
dan.micuda@gmail.com

Abstract

More and more in recent times credit institutions are replacing traditional brick and mortar agencies with technology focused on changing the behavior patterns of customers and streamlining the delivery process of their services. The main factors that promote this growing trend are the increasing cost of personnel and the reliability associated with these new ways of service delivery with the aid of technology. Although this is an increasing trend, there are still banking services that require a high level of interaction between the client and the bank personnel, thus combining bank employees and technology in one smooth process of service delivery it is often a difficult task to achieve for decision makers.

The present paper examines the different ways that can be taken in order to build and improve a superior service delivery process and the consequences that decisions at this level have on customer satisfaction and retention.

Key words: banking services, delivery processes, quality

J.E.L. classification: M31, G21

1. Introduction

The process is defined as how the service is delivered to the customer. In the banking institutions that can take different forms depending on the service / product that is offered to the client.

If it's a loan, the process will involve a series of standardized steps that allow the credit counselor to interaction with the future credit beneficiary in order to collect data,

calculate and analyze his credit scoring and decide whether the loan terms takes into account the banks rules and regulations. In the case of other banking services such payment of bills or a credit rate, the process is more simplified, even tending toward automation.

Only in recent years researchers focused on this new topic of how the service is delivered and the implications on various aspects regarding the banking customer such as satisfaction, loyalty or retention [1],[2], [3].

2. Service delivery process design in banking environments

Services can be described in terms of operations that are involved in their delivery. They can take three basic forms, namely:

- in-line operations, favorite when the product / service offered by the bank shows a high degree of standardization and the delivery process takes the characteristics of a routine (Ex. cash disbursement from the bank ATMs)
- "shop jobs" type operations, the most type of interactions seen in banking, where the credit institution provides various services that meet the needs of each client, using different processes and sometimes different deliver personnel (credit, taking deposits, granting of letters of guarantee, business consulting, etc.)
- Intermittent operation, used if the service provided has a low degree of repeatability and each process involves a specific way of delivery (advising clients to access different funding sources).

Although recent research [4] indicates that many current bank customers desire a high degree of human interaction that can only be

provided by bank personnel the majority of banking institutions are oriented towards technology investment that aim to replace human interaction with a more reliable and easy to control technological process.

Banks, as the forerunners of the market economy, are quickly seizing the opportunity to invest in technology in order to improve the service delivery process with beneficial consequences on cost control, attracting new customers and meeting the requirements of the existing ones[5].

But recent developments and studies have shown that simply delivering something through a technology-based interface it will not guarantee to work simply because it is technology. This study [6] compared three self service technologies processes widely adopted by the banking institutions (ATM's, bank by phone and online banking) and finds that the technology must be useful and easy to use (ATM's) and simply being useful doesn't ensure adoption by customers (bank by phone).

The present evolution stage at bank level is defined by a combination of both human and technology that form a so-called "human/machine hybrid" system of service delivery. From this perspective some authors [7] have identified seven challenges that banks face in managing this particular form of service delivery processes:

1. Conceptualizing the framework
2. Choosing the value offer
3. Planning and rolling out the process
4. Delivering service through multiple coordinated points of contact
5. Communicating with and educating customers
6. Tracking performance in terms of process, outputs and financial implications
7. Coordinating interdisciplinary activities, including management information systems, marketing, operations, human resources, computing and finance.

The main concern of banks regarding the delivery process is to optimize its efficiency without sacrificing quality service. Under this requirement, banks take into account various aspects such as:

- the steps required by the customer service delivery and their logic succession;

- the possible removal, rearrangement or a combination of certain stages to achieve a more efficient process of delivery;
- involvement of consumers in each step required by the delivery process, reducing or eliminating its participation;
- different ways to automate certain steps or even the whole process.

The importance of ensuring an efficient management of the process is given by the need to ensure high levels of availability and quality of service. In the absence of a coherent process of implementation and monitoring of service delivery, the burden to balance supply and demand for the banks services becomes extremely difficult. Services, by their inherent nature, can not be stored and therefore the credit institutions must find different ways to cope with peak demand times, when requests from customers grow significantly.

Operations Management is an area intensively studied in marketing management of products. In the services sector, where we have to deal with an intangible product, it plays a vital role in ensuring customer satisfaction because very often the delivery process becomes the service itself. A number of factors [8] affect the effective management of critical processes (Table 1.) that have an impact on customer satisfaction. These factors are in fact different ways in which the banks can secure a competitive advantage over competitors.

Table 1. Factors that affect the effective management of critical processes

Nr.	Influence	Explanations
1	Process planning and control	Specifying operations planning and control processes in order to achieve a high level of services quality provided in terms of quantity, quality, delivery and cost
2	Operations planning	Detailed specifications for each operations subsystem
3	Physical facilities design	Physical facilities design, construction, location, maintenance and related materials handling services

4	Planning	Further details of performance times of various operations regarding the service for which that the bank has committed to a more efficient use of available resources
5	Staff planning and control	Planning and control their staff and production capacity in relation with their services
6	Quality control	Imposing and monitoring quality standards in each service system
7	Operations control	Ensuring input and output information flows through the service system and the proper execution of transactions according to a specific program
8	Predicting and long-term planning	Anticipating customer demand and forecast production capacities necessary for the consistent operation of the service

For an easier approach, the service delivery process is often called a service blueprint [9]. This is actually a chain of processes necessary for the effective delivery of a banking service, a map of processes, elements, activities and the interaction between them can be viewed at a glance and therefore better optimized.. For its construction a series of steps are required [10]:

1. Draw all processes and components in the form of a chart. The more complex the service is, the more elements the blueprint will contain;
2. Identifying the 'points of failure "where the process can fail;
3. Setting standards of performance and acceptable tolerances for each operation. They usually take the form of maximum lengths of time required for that phase;
4. Identify all visible elements for the client and their delimitation by a "line of visibility;

5. Analysis the overall profitability and the impact this delays have on the hole process and the different cost that can be incurred by them.

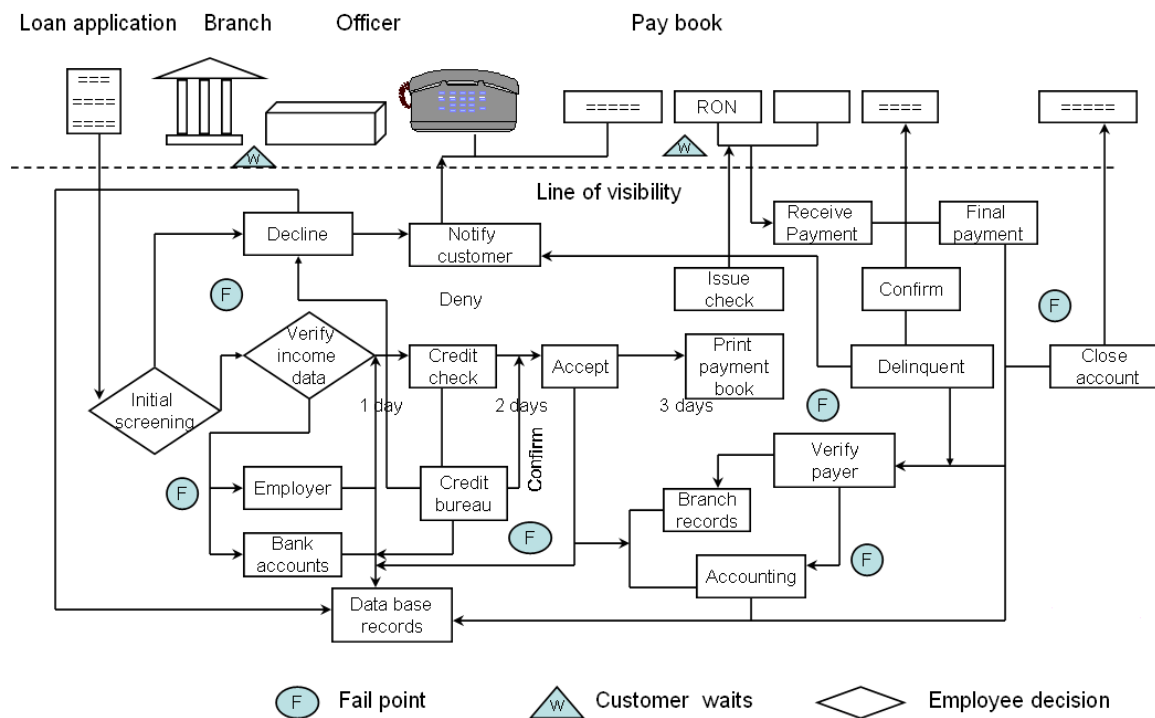

A 2002 study [11] on US bank customer's perceptions of the impact of technology on service delivery in the banking sector the authors note that "managers should determine the parameters of their customers zone of tolerance. In other words, managers need to know the approximate threshold between satisfaction and dissatisfaction with the core service they are receiving from their bank". This is an important prerequisite and also a starting point of the process design mechanism.

The service schematization process is an effective method for its design and diagnosis. In the case of banking institutions, whatever is the ultimate goal of this process, whether a circuit description of the bank's confidential document is desired or an entire service or product evaluation, the goal must always be to improve the delivery process in order to promote customer satisfaction and to increase the efficiency with which the institution uses its human and material resources. This method allows the management to pinpoint the "Failure Points ", moments of truth for customer and employee. Their negative influences and possible consequences should be eliminated or reduced in order for the bank to attain a high degree of customer satisfaction.

Figure 1. [12] presents a service blueprint for the granting of a loan, along with points of failure, line of sight and waiting. It is noted that although the main process is quite complicated, it is located below the most visibility of hidden client, which can cause frustration and discontent on his part relative to the waiting time required to access the credit funds.

It is therefore important for the bank staff to explain in detail the processes and methodology required by the credit analysis in order to eliminate consumer dissatisfaction and not to create unrealistic expectations.

Figure 1. Credit lending Process

From an organizational point of view, service schemes allow each employee to understand the role it plays in the delivery of a specific banking service, highlights unknown tensions in the organization and allows the front-office employees to express their views on how to service is offered. It is therefore very important to assess the perspectives of both management and employees about how the service delivery mechanisms of the services offered should run. This is especially important given the key role of contact employees in delivering high quality services[13].

There are even more important aspects that must be taken into consideration: the attitudes and perspectives of the bank customers about the service delivery process. Although very often they don't have very much insight into the bank operation processes and the regulations that governs them, they can offer surprisingly valuable advices and information regarding mainly front-office processes, information that is often disregarded and passed by the bank staff. The client often has "the small picture" of service delivery processes that must be reframed and included in the "big picture" of bank operations by the management.

3. Conclusions

Designing streamlined service delivery processes for the bank services or products in particular or for the operation as a whole is a prerequisite of customer satisfaction especially in the banking industry where clients are expecting rigor and diligence from their financial services supplier.

Repeated failures in these processes that are not corrected in a timely manner will eventually lead to customer dissatisfaction with the bank, lack of loyalty and, in the end, to losing customers, with a major impact on both market share and financial performances.

A Comparative Analysis of Corporate Governance Structures in Europe, USA and Latin America

Avadanei Anamaria

„Alexandru Ioan Cuza” University of Iasi, Doctoral School of Economics

anamaria_avadanei86@yahoo.com

Abstract

The aim of the present paper is to highlight the characteristics of corporate governance structures in three main areas: Europe, USA and Latin America. This paper offers an overview of the common elements and divergent points of the corporate governance models following the particularities of the selected regions. In order to identify the main directions of reform, we discuss the nature and structure of corporate regimes. To conclude, we can't speak of a single set of global corporate governance standards, but rather convergence on selected issues within regional blocs. New tendencies generated by the financial 'underworld' demand for a solid reform.

Key words: corporation; financial crisis; corporate governance; corporate social responsibility

J.E.L. classification: G30, G34, G01

1. Introduction

The high degree of communications development and technological innovation has revolutionized transfers between corporations, influencing the implementation of decisions orientated to an increasing virtual reality. Corporate perspective changes substantially, from the real economy to artificial engineering so that in recent years, diverse opinions point to an "irrational exuberance" of creating value within companies. In modern society, governance is seen as an interrelated mechanism of government institutions, civil society and economic forces.

In the first part of this paper we proposed a review of the literature in order to outline the features of corporate governance.

Defining a detailed framework of the corporate governance theories, in the second and third sections we offered a three-dimensional vision of corporate governance models in the United States of America (USA), Europe and Latin America.

The analysis has the role to highlight the common solutions for improving corporate governance models and to create a new perspective.

2. Literature review. Corporation and corporate governance-“a true bond”

Considered a reaction to the problems of modern society, corporatism uses the incorporation of divergent interests of manufacturers to control them in order to maintain power.

Initially, corporate governance relied on legal issues, structures, individual skills and independence [13]. The stage of development was completed by the commitment of stakeholders and the emergence of new models of accountability. As current corporate governance features, we distinguish partnerships and complex transactions that require monitoring and performance measurement [4].

Corporate governance can be defined following two directions. In terms of behavior it studies efficiency, growth, financial structure, treatment of shareholders, corporate performance - summarizing its current behavior. In light of the regulatory framework, reporting is done according to the rules under which firms operate (the sources of the legal judicial system, financial market or labor market) [6].

The premises of corporate governance growing importance are the followings: cyclical financial crises; enhancing and repositioning the role of investment process; technological development, liberalization, structural reforms which redefine the local

and global landscape. Institutional arrangements of corporate governance are being replaced by new ones in order to reduce inconsistencies and gaps caused by progress. The allocation of capital, as a complex process associated with financial market liberalization, deregulation and price competition increases market risk exposure. The international financial integration (increased trade and investment flows) has led to controversy on corporate governance due to national characteristics [8].

Corporate governance can be analyzed as a three-dimensional relationship: between shareholders, creditors and corporations, between financial markets, institutions and corporations, or between employees and corporations [2]. The present crisis appeared from the inability of delivering the expected results of corporate governance, as a consequence of poor implementation of an efficient strategy or folly and unauthorized management implementation.

Separation of responsibilities leads to independence, namely in defining and implementing corporate strategy. A stable working environment, solid-built policies and ethical corporate culture are key elements of the efficient functioning of Directors Board. Establishing a balanced financial policy stimulus has been a weakness of corporate governance, increasing financial compensation not being correlated with the performance level [7].

The corporate governance control mechanisms are designed to correct deficiencies that occur, but become ineffective when there is the phenomenon of overvaluation. Fraudulent defending of an excessive market capitalization, leads in fact, to the collapse of some financial institutions well positioned.

Corporations set their goals, measure their performance, which will be independently audited, compared with the three dimensions of sustainable development: economic, social and contextual. Corporate social responsibility influences the profitability level, generates internal loyalty, provides support and discourages foreign criticism [14].

3. Shareholder model vs. stakeholder model

In the academic literature, theories on corporation offer three alternatives in order to understand its purpose. According to a first view, the corporation place as priority the investors' interests and the role and responsibilities of the Directors Board intended only to protect the shareholders interests.

From another perspective, both the interest of investors and other participants affected by decisions are important: suppliers, customers, employees, local community and environment. The management acts as agent for these groups. In this case, the Board of Directors serves the interests of all participants in corporate activity.

A third view, the middle rank one, includes and scale the previous assumptions, so the protection of investors is dominant, but there are also considered the interests of other groups, namely the establishment of corporate accountability, without compromising the needs of society and its members. Practical experience shows that all three approaches are on the market: examples are the USA and the European countries (notably Germany in the case of the second approach).

The legal nature of the corporation is different in United States of America, United Kingdom (UK) and continental Europe. The analyses show similarities between the USA and UK, named Anglo-Saxon corporate governance systems; in Europe there is a continental corporate governance system which includes internal variations.

According to the concession theory, in the USA, the Board of Directors is the heart of corporate governance. In the UK, corporation is defined as a legal member association. The essence of the council is to delegate members as agents of company shareholders. The property and control are dominated by large institutional investors. In continental Europe prevails stakeholders perspective and the public interest but differences came from the corporate control style.

In the last 20 years, the corporate governance system from the USA suffered important changes. Enron, WorldCom, Tyco are examples of dysfunctional corporate governance mechanisms. The question is:

what went wrong?

Before 1980s, the aim of the corporation was to ensure firm growth, the external mechanisms of the governance were rarely used, hostile takeovers were unusual, the corporate management was dominant and the council control was reduced. The major objective of long-term performance plans was to increase selling and shares value. Shareholders behavior led to multiple takeovers and reorganizations [9].

Table 1. Determinants of the shareholder model

Anglo-Saxon-American Model
• Large-scale publicly traded corporations
• Short-term management
• Low concentration of institutional investors
• Decentralized markets and the individual interest function in a self-regulation framework
• Profit orientated behaviors, individualism
• Well developed corporate governance mechanisms (the market for corporate control, regulation, contractual incentives)
• Corporate social responsibility
• Coalition control
• Low influences of investors over corporation management
• Individual investors high protection, strict rules for information dissemination and internal transactions
• A heterogeneous labor market, instability, a reduced internal flexibility, professional and geographical mobility
• Employee's reduced implication in strategic decisions. In the USA, corporations developed special programs for employees in order to participate in operational decisions
• Performance related financial incentives (especially in the USA)
USA, UK

Source: [5]

The Anglo-Saxon model is characterized by a low concentration of investors compared to the continental model. The central elements of the corporate governance system are the stakeholders' interests and the active role of employees in the strategic decisional process [1].

In recent years, the profile of the private investor has become an institutional one. Majority in UK and the United States of America, institutional investors display an increase in continental Europe also.

Differences are related to their interventionist nature, the exposure of Directors Board to certain pressures, appointment of new members and executive remuneration (United Kingdom).

Table 2. Determinants of the stakeholder model

Continental Europe Model
• Small and medium corporations
• Long-term management
• High concentration of private investors
• The major role of banks and the interaction between corporations and banks creates a stable economic environment
• Long-term profit orientation
• Corporate governance mechanisms are related to direct control and low managerial incentives
• Corporate social responsibility
• Shareholders direct control
• Direct and indirect influences of investors and banks over corporation management
• An increased minority shareholders protection, information transparency in order to reduce possible distress
• There is a codetermination chain between the Board of Directors, the Work Council and employees, with the effect of reducing mobility inside corporations
• The employees have an active role inside corporation through works councils and trade unions
• An increased tendency of incentive scheme based on performance
Germany, Holland, Austria

Source: [5] [12]

Concentration of ownership leads to reduced effectiveness of external mechanisms of corporate governance (corporate control exercised by the market and investor activism) in order to protect capital providers (Continental Europe).

Legislative agenda in the USA and UK highlights the need to increase and improve investor activism. Differences between this

two countries relate mainly to shareholder rights (the right to convene extraordinary meetings (UK case), limited access to regular meetings, campaigns, voting initiatives (USA case). As a result of the pressure generated by U.S. institutional investors active in continental Europe the interactions between shareholders tend to get a cross-country dimension [10].

The fundamental difference between Europe and the USA is that although European reform aimed at adopting U.S. similar laws, the move towards reducing managerial opportunism is not an appropriate way to prevent trading in someone's own interest. U.S. solutions, adopted to reduce management deficiencies do not affect earnings of major shareholders. Recent developments define European corporate governance process classified in Europe as an ongoing reform [5]. The market corporate control constitutes an important mechanism of corporate governance. Depending on corporate governance systems, this mechanism can be highly active (USA, UK) or almost nonexistent (Germany, Netherlands, China).

Table 3. Deficiencies of corporate governance in the USA and Europe

	Deficiencies
USA	<ul style="list-style-type: none"> • Monitoring failures by the Board of Directors; • Excessive payments underevaluation; • The incapacity of institutions to manage audit deficiencies; • The equity overevaluation problem.
Europe	<ul style="list-style-type: none"> • Independency and financial responsibilities of the council; • Minority shareholders protection; • Difficulties to support an active market for corporate control.

Source: [11]

A detailed analysis of the Directors Board indicates differences related to the main features: board size, independence from management, directors' experience, the endogeneity of the structure. In the USA, independent boards are associated with superior corporate performance, and the board size varies inversely with the performance. A common element in the U.S. and most European countries is the one-level

structure of the Directors Board, with the exception of Germany and Austria (a two level-architecture) and France and Finland where there is the possibility of a choice between the two structures. The two-tier system faces different problems in relation to its monitoring function: large size, inadequate flows of information, occasional meetings and in some cases the underdevelopment of the committee structure [15].

A common problem of corporate governance systems in the last few years reflects a high level of compensation, especially in the USA. Excessive compensation is determined by external costs as a result of various negotiation methods, strategic errors, an increasingly number of executive members and a misallocation of responsibilities from compensation committee to human resources department.

The nature of legal systems influenced national systems development and highlighted corporate governance deficiencies. In continental Europe, the corporate governance model is based on civil law, but in Anglo-Saxon countries and USA, the model follows common law path. In the first case, the negative aspects came from excessive executive payments and a reduced efficiency of internal and external monitoring. In the civil law system, minority shareholders rights are not a priority, but the shareholders have an active role in management monitoring.

4. Latin America: far behind?

The countries from Latin America do not witnessed failures of financial institutions generated by corporate governance systems. An explanation for the absence of corporate scandals in this region is the low level of investor protection and transparency. External influences and political governance considerations are determinants of capital flows in Latin America.

Weak developments of financial markets and a reduced presence of institutional investors place Latin America on an inferior position considering the complexity of corporate governance system. Capital markets are not real financing sources because of insignificant economic experiences and a reduced political stability.

The analysis of strengths and weaknesses in these seven countries of Latin America offers a large view on the potential development towards corporation-investments-regulation.

Chile and Brazil have the most competitive economies, well defined corporate governance mechanisms and consistent regulations, but they still place on an inferior position compared to United States of America and Europe.

Table 4. Strengths in Latin America's countries

Country	Strengths
Argentina	<ul style="list-style-type: none"> • Entrepreneurial activism; • The quality of accounting standards;
Brazil	<ul style="list-style-type: none"> • Permissive regulations for institutional investors; • The quality of accounting standards; • Fiscal policies; • Bankruptcies procedures; • Capital markets development; • Corporate governance.
Chile	<ul style="list-style-type: none"> • Well defined regulation for investors; • Developed capital markets; • Legal transparency.
Columbia	<ul style="list-style-type: none"> • Investments regulation; • The protection of minority investor rights; • Corporate governance.
Costa Rica	<ul style="list-style-type: none"> • The quality of accounting standards; • Fiscal treatment; • The legal system; • Openness to foreign investment portfolios.
Mexico	<ul style="list-style-type: none"> • Fiscal treatment; • Corporate governance; • The protection of minority shareholder rights.
Peru	<ul style="list-style-type: none"> • The use of international accounting standards; • Corporate governance; • Openness to internal investments.

Source: [16]

Low levels of transactions reveal the inactivity of capital market from this region.

Starting with 2005, the scandals from Asia, Europe and the United States of America determined a repositioning of investor protection as a top priority of the corporate governance system.

Compared to continental Europe countries, Latin America assures a low level of investor rights protection. Inadequacy of legal institutions generates a high level of property concentration, a reduced access to external financing, deficiencies of law enforcement and inefficiency. Corporate control is made by the principal shareholders [17].

Table 5. Weaknesses in Latin America's countries

Country	Weaknesses
Argentina	<ul style="list-style-type: none"> • Corruption, bureaucracy, the political influence and the lack of a stable framework discourage investments.
Brazil	<ul style="list-style-type: none"> • Constrains and procedures associated to intellectual property; • Corruption massively manifested in the public sector; • Structural deficiencies in the political and legal systems.
Chile	<ul style="list-style-type: none"> • Requirements of internal investment portfolios; • Transition to international accounting standards.
Columbia	<ul style="list-style-type: none"> • Corruption, deficiencies of the local legal system; • Restrictions on the capital market in terms of liquidity and size; • Transition to international accounting standards.
Costa Rica	<ul style="list-style-type: none"> • Low level of protection of minority shareholder rights; • Restrictions for the institutional investors; • Entrepreneurship; • Corporate governance.
Mexico	<ul style="list-style-type: none"> • Legal framework for the investment activity; • Corruption, the role of authorities in controlling.

Peru	<ul style="list-style-type: none"> • Investment regulations; • Fiscal regulations; • The protection of minority shareholder rights; • Corruption.
------	---

Source: [16]

The Boards of Directors, their role and practices highlight the fact that compared to United States of America and Europe these structures are weak mechanisms of the corporate governance.

In a region characterized by economic volatility and repeatability of financial crises, corporate social responsibility is mostly influenced by the actual social problems: poverty and inequality. This concept was adopted around 1997 and the most active country was Brazil followed by Mexico. One of the channels used in public and private sectors with the aim to reduce poverty is the entrepreneurial channel.

The vision of corporate social responsibility is different in USA, Europe and Latin America. In Latin America the motivation is to reduce social pressures, poverty as well as the improvement of corporate sustainability; in the United States of America the corporate social responsibility is similar to corporate philanthropy; in Europe the concept is often associated to day-to-day management responsibility [3].

5. Conclusion

The international financial crisis reveals the importance of corporate governance systems. Strong deficiencies, large gaps between regions, low control mechanisms outline an instable corporate environment, prone to unjustified actions.

The governance exposure and risks should find solution in a proper evaluation of information. A clear distinction between roles and responsibilities is a basic requirement in every corporate governance model and the power of supervision leads to efficient operational activity. The reform priorities in the selected areas refer to the quality of regulation, auditing, transparency and integrity, interests' independence, regional cooperation and adequate remuneration schemes.

Corporate social responsibility has the role to strengthen the relation between corporation and society, with long-term positive effects. Deficiencies of corporate governance are reflections of national problems, so that reform is a necessity, an important step to corporate consolidation. Rethinking strategies and repositioning the role of the participants offer new perspectives for reconstruction!

Analysis of Territorial Disparities Using Two-Way Dispersional Analysis

Babucea Ana-Gabriela

Răbonțu Cecilia Irina

"Constantin Brancusi" University of Targu Jiu

babucea@utgjiu.ro,

cecilia.rabontu@gmail.com

Abstract

Economic phenomena and processes are often influenced by more than one factor with simultaneous actions. To highlight the extent to which one or more factors, or combinations thereof, affects essentially on a dependent variable, we use analyze of variance. This statistical method does not explain the relationship between variables, but only verify the deviation between the empirical from the theoretical values of the variable, and the extent to which these changes are not dependent by the factor/factors clustering. Therefore, analysis of variance method can be used both before and after application of correlation and regression statistical methods. This paper illustrated a pattern of use of the method to determine the significance of two factors, level of training and gender disparities in regional unemployment in terms.

Key words: regional disparities, unemployment, two-way analysis of variance, assumptions, F-test

J.E.L. classification: E2, J1, R12

1. Introduction

Dispersional analysis is known as analysis of variance, ANOVA. Despite the name, it is a statistical test used to determine significance of statistical differences between three or more samples (dependent or independent), measured on a proportional scale. Similar with t-test for more than two samples, this method, introduced by statistician RA Fisher, check the deviation between the real values of a variable from

theoretical values, calculated the average size or form of regression equations and how these changes are dependent or not the grouping factor.

Analysis of variance is used for verifying the dependent variable (z) to the factor (s) of grouping, in which case it is regarded as ancillary, applied before and after specific correlation and regression statistical methods. Also, the method can verify the independence of an outcome variable to a data systematization variable, in which case dispersional analysis method is considered independent. Dispersional analysis is based on grouping method. This separates the influence on the result of variable factors as determinants of influence accidentally registered.

So, dispersional analysis method is based on observed data by grouping one or more criteria and highlighting the influence of effects depending on the individual criteria were then grouped observations. Usually it use: a grouping variable X (which determines the subgroups), also called independent variable and a variable analyzed (dependent), measured on proportional scale;

The dependent variable is divided into k subgroups of size n_1, n_2, \dots, n_k . The discrepancies found between the mean subgroups 1 ... k, ANOVA decomposition uses the notion of total variation of internal variation (within these groups) and external variation (difference between groups).

Once detected effects, testing takes place by comparing the variances caused by varying factors, the dispersion caused by accidental factors acting on the process studied. Number of criteria which are grouped by the number of parameters depends included in the analysis.

2. Database

The considered data refer to the official data available on the website of National Institute of Statistics online database TEMPO-Online - time series, and refers to the unemployed population of the eight regions distributed by level of education and gender at the end of 2009.

Table 1 - Registered unemployed categories of unemployed by regional development, level of education and gender

Year 2009

3. The analysis of territorial disparities using two-way dispersional analysis

The model identifies the two-way analysis dispersional two factors of influence, and characteristic variability result can be explained by the influence of the first factor (with i levels) to the second factor (with j levels), the interaction of two factors influence considered and the residual factor (chance).

Dispersional F-test analysis requires additional conditions are met: the variable studied is normally distributed in the r groups and dispersions are equal.

These conditions can be easily verified constructing histograms for each of the r samples. F test is done, then, by comparing calculated values with critical values.

If you want to know whether the level of training and gender disparities in the unemployment determine their structure relative to the eight development regions of Romania, on the premise that the development of geographical region and level of their specialization reflected in application for a labor market in terms of

both the characteristics of the active population.

In the training level was taken into account and distribution by sex nominal variable can be seen as an indirect variation caused by this variable.

We have the model:

$$x_{ijk} = \mu + \alpha_i + \beta_j + \gamma_{ij} + \varepsilon_{ijk}$$

where each observed variable, x_{ijk} , is equal to a suffering population mean, μ , which has a row deviation α_i , column deviation β_j , row and column interaction between γ_{ij} and an experimental error, ε_{ijk} .

Interpretation of test results shall be calculated F value of F is compared with the theoretical value for each factor separately (X, Z, and XZ) as unifactorial ANOVA.

F test will help this time, to calculate not only the main effect of each factor but one indicator will be calculated both for assessing the interaction effect and to test the statistical significance of the entire model, so the overall factors (individual + interaction between them).

There are three sets of assumptions, corresponding to those two factors and their interactions.

➤ For X - factor

Null hypothesis - H0: X is not a significant factor (group as factor X is not significant or group environments where X - lines do not differ significantly);

Alternative hypothesis - H1: X factor is significant (X factor is a significant group by group or environments where X - lines differ significantly)

➤ For Z - factor

Null hypothesis - H0: Z factor is not significant (group by the factor Z is not significant or group environments where Z - the columns do not differ significantly);

Alternative hypothesis - H1: Z is a significant factor (Z factor is a significant group by group or by Z-column averages differ significantly).

➤ For XZ - interaction

Null hypothesis - H0: the interaction of factors X and Z is not significant (effect of X does not change the level of Z)

Alternative hypothesis - H1: the interaction of factors X and Z is significant (Z's effect depends on the factor Z).

Since accepting the null hypothesis of each test shows that the ANOVA F statistic is calculated on the register as a distribution F

with degrees of freedom numerator and denominator of the numbers attached, then:

- for XZ: rejecting the null hypothesis if:

$$F_{XZ} \geq F_{1-\alpha; v_{xz}; v_{rez}};$$

- for X: rejecting the null hypothesis if:

$$F_X \geq F_{1-\alpha; v_x; v_{rez}};$$

- for Z: rejecting the null hypothesis if:

$$F_Z \geq F_{1-\alpha; v_z; v_{rez}};$$

Obviously, it can happen that both factors are determinants, only one or even none.

If considered to constitute sets of statistical assumptions:

➤ **X Factor:** The level of training of unemployed

H0: structural differences in the developing regions relative to the number of unemployed are not influenced by their level of preparedness;

H1: Structural differences in the developing regions relative to the number of unemployed are influenced by their level of readiness.

➤ **Z Factor:** Gender unemployed

H0: structural differences in the developing regions relative to the number of unemployed are not influenced by gender;

H1: Structural differences in the developing regions relative to the number of unemployed are influenced by gender.

➤ **Interaction XZ:** Level of training - unemployed Sex

H0: structural differences in the developing regions relative to the number of unemployed are not influenced by gender;

H1: Structural differences in the developing regions relative to the number of unemployed are influenced by gender.

We calculate the number of degrees of freedom for each factor influence df_1 and the number of degrees of freedom df_2 for experimental error.

$$df_1 = (r-1) \times (c-1) = (3-1)(8-1) = 2 \times 7 = 14$$

$$df_2 = (k-1) \times r \times c = (2-1) \times 3 \times 8 = 24$$

$$\alpha = 0,05$$

$$F_{tr(2,24)} = 3.40$$

$$F_{tc(7,24)} = 2.42$$

$$F_{ii(14,24)} = 2.13$$

Correction factor C is determined by the formula:

$$C = \frac{T_{ij}^2}{rxcck} = \frac{709383^2}{48} = 10483838347.68$$

It will determine the sum of squares for each factor of influence:

$$SPR = \sum_{i=1}^3 \frac{T_{i.}^2}{c \times k} - C = \frac{502995^2 + 156352^2 + 50036^2}{16} -$$

$$- 10483838347.68 = 166.89$$

$$SPC = \sum_{j=1}^8 \frac{T_{.j}^2}{r \times k} - C = \frac{84109^2 + 105439^2 + \dots + 64850^2}{6} -$$

$$10483838347.68 = 1008168849.81$$

$$SPRep = \sum_{i=1}^3 \sum_{j=1}^8 \frac{T_{rep}^2}{k} - C =$$

$$= \frac{(36218 + 21285)^2 + (8908 + 10767)^2}{2} - 10483838347.68$$

$$= 16677610196 - 10483838347.68 = 6193771848.3$$

$$SPI = SPRep - SPR - SPC = 6193771848.31 - 166,896 -$$

$$- 1008168849,81 = 5185602831.60$$

Table 2 - Distribution of unemployed in developing regions by level of education and gender,

Year 2009

Education level	Gender	Development region								Tj
		North West	Center	North East	South East	Bucharest-Iloft	South Muntenia	South West Oltenia	West	
Primary, secondary and vocational education	Males	36218	46519	56080	45232	8590	56478	40937	12600	502995
	Females	21285	27840	29275	28605	7208	32961	25698	17635	
Secondary and post-secondary education	Males	8908	10729	9997	6783	4269	11808	13408	7481	156352
	Females	10767	13215	11346	9116	5382	13134	10768	9251	
University	Males	2872	3133	3326	2244	1929	2468	2726	2700	50036
	Females	4059	4013	4082	3038	2677	3454	3986	3349	
Tj		84109	105439	114086	93018	30055	120303	97523	64850	709383

Determine the sum of the squares on the entire table:

$$SPT = \sum_{i=1}^3 \sum_{j=1}^8 \sum_{k=1}^2 x_{ijk}^2 - C = 36218^2 + 21285^2 + \dots + 3349^2$$

$$- 10483838347.6875 = 9919389373.31$$

Sum of squares for experiment error is then determined:

$$SPE = SPT - SPRep = 9919389373.31 - 6193771848.31 =$$

$$= 3725617525$$

The next step: determined the mean of squares for each factor of influence:

$$MPR = \frac{SPR}{df_1} = \frac{166,896}{14} = 11,92$$

$$MPC = \frac{SPC}{df_2} = \frac{1008168849.81}{24} = 42007035.41$$

$$MPI = \frac{SPI}{df_1} = \frac{5185602831.604}{14} = 370400202.26$$

We determined the mean of squares for experiment error:

$$MPE = \frac{SPE}{df_2} = \frac{9919389373.31}{24} = 413307890.56$$

Next, we calculate the F-ratio for each influence factor:

$$F_{cr} = \frac{MPR}{MPE} = \frac{11,92}{413307890,56} = 2.884048499533846E - 8$$

$$F_{cc} = \frac{MPC}{MPE} = \frac{42007035,41}{413307890,56} = 0.102$$

$$F_{ci} = \frac{MPI}{MPE} = \frac{370400202,26}{413307890,56} = 0.896$$

$$\text{How, } F_{tr(2,24)} = 3.40, F_{tc(7,24)} = 2.42,$$

and $F_{ii(14,24)} = 2.13$ comparing these values with the calculated values:

➤ as $F_{cc} < F_{tc(7,24)}$, the null hypothesis is accepted, so the structural differences in the developing regions relative to the number of unemployed are not significantly influenced by geographic regions;

➤ as $F_{cr} < F_{tr(2,24)}$, the null hypothesis is accepted, so the structural differences in the developing regions relative to the number of unemployed are not significantly influenced significantly by their level of preparedness;

➤ as $F_{ci} < F_{ii(14,24)}$, the null hypothesis is accepted, so the structural differences in the developing regions relative to the number of unemployed are not significantly influenced by gender and level of education the unemployed.

4. Conclusion

It appears that none of the factors considered are structural differences in the determinants of queen development regarding the registered unemployment in the year 2009, i.e. the differences are not significant disparities are caused by other factors of influence.

In other words, neither the profession nor gender differences are not significant for the unemployment rate in Romania in the

geographical regions as administrative nuts; the disparities were caused by adaptation to different situations of economic and financial crisis.

It is difficult to estimate the impact of the crisis in the regional labor markets due to lack of statistical data.

Data are not sufficient to estimate the regional tendency; however, knowing the impact of the crisis indicators at national and regional developments in the last two years, general estimates can be made based on certain assumptions.

The main hypothesis could be that if there was a crisis and therefore lack of jobs in all areas of activity at regional level would be significant differences concerning unemployment level of education and sex, determined by specific economic disparities of them.

Management an Inexhaustible Resource of Development in the Context of Globalization of Firms' Activities

Băeșu Camelia

„Ștefan cel Mare” University of Suceava,
Faculty of Economics and Public Administration
cameliab@seap.usv.ro

Abstract

Lately at world level there have been recorded transformations of society in general and of the production activity in particular, as a consequence of some qualitative changes from different fields such as the technological one (information becomes a new major source of the company), commercial, sociologic and politic ones as well (the events from the ex communist countries). At national level there have emerged new exigencies regarding the productive companies in view of getting them adapted to the system of market economy.

All these external and internal constraints require more and more the intensification of information exchange in all fields, including the management field.

Highly performing management from the end of the 20 th century and the beginning of the 21 st is characterized by the manager's total involvement in the firm company he is managing by drawing and motivating all those involved in carrying out processes in the firm.

Key words: management, transformations, manager, globalization, firm

J.E.L. classification: M1, M14, M16

1. Introduction

Over the last two decades, a series of radical transformations emerged in the world economy have caused large comments, especially on the explosive increase of unemployment, of uncontrolled rhythms of inflation, contradictory evolution of the economic integration process, budgetary deficiencies, technological changes, severe competition, environment damage, all

together being major problems, the solving of which has never been considered satisfactory. Economists have tried to answer by different solutions, but they have not succeeded in bringing to the end and drawing relevant conclusions.

Gradually the economic theory felt the need to use new concepts capable of explaining with higher accuracy the huge transformations that have occurred lately in the world economy. One of these concepts which decisively contributed to the understanding of nature and all consequences of these changes is that of *economic globalization*.

Other authors define the globalization process starting from a seemingly easy question: "What has this new process of economy brought about?" Trying to answer this question the above mentioned authors place the increase of interdependence on the first position, showing that the events taking place in some countries are significantly related to what is going on in other states of the world. Therefore, the globalization process is being regarded as a long-term modality or system of perception and approach of big contemporary problems, determined by the interaction of multiple processes and phenomena from the economic, technical, political social, cultural and ecological point of view. [3] A system of interdependent markets has been created, which makes the firms to adopt necessarily a valid *global strategy* for the whole planet which leads to competition globalization. Thus, as the markets are becoming interdependent, the companies are coordinating their strategic activities abroad, competition acquiring a much greater role. Due to this fact, the consequences of competitive success or failure from a national market will have an important impact upon

the overall firm competitiveness, being felt all over the world.

Globalization does not refer only to firms' activity and commercial fluxes caused by the former ones, but it includes equally financial globalization too which plays a significant role in the world economy. Some studies devoted to this issue consider that globalization should be regarded as a specific stage of capital internationalization and rendering obvious its profitable possibilities at the whole scale of world areas, namely everywhere there are resources and markets. Thus globalization is being dealt with in a larger context, being the conjugated result of two distinct moments but tightly related between them [4]. The first moment is related to a longer accumulating period of capital which has begun after the First World War ceasing but interrupted by crises and devastating wars such as the Second World War. The second moment is marked by the adoption of some liberalizing, privatization and legislative measures of economic international life put into practice at the beginning of the eighties. All this has led to partial loss of the capacity to promote a self-centered and independent economic development, together with the disappearance of some specific traits of national markets. Exchange liberalization and emergence of new performing technologies determined the big industrial groups to get organized in "network firms". Consequently the capital accumulating process is being stimulated, by taking advantage of the new opportunities offered by automation. Due to these major changes occurred in the contemporary economy, the speciality literature ascertained a new emerging phenomenon that is of the world oligopoly – phenomenon regarded as a "market form" framed within an industrial "rivalry space". This space has been formed on the basis of world expansion of big companies and interaction between the investments promoted by these ones in the USA, European Union and Japan, being a natural result of the economy globalization process.

2. Management, an inexhaustible resource of development

There are great differences between the developed European countries from the point of view of their economic development and there are still other ones regarding the development level.

In England, for example, in the eighties numerous changes in the field of industry dimensions and complexity took place as well as in that of ownership access, leading to a more stressed separation of the manager quality from that of owner, such as follows [1]:

- the changes in the economic policy from the seventies determined by the "oil shock" have led to inflation, increase of unemployment and generally economic recession;

- transformations in the management field in the context when new alternatives for the traditional capitalist firm were looked for;

- transformations in the legislative field stimulating the profit obtaining from shares even by managers;

- new technologies having implications on the whole labor force.

The English management is based on firms' organization as holding, flexible structure decentralized from the decisional point of view, having coordinating means at different levels. Holding as legal entity and management instrument is generally characterized as follows: it functions as managerial apparatus at the managing level being composed of a reduced number of persons dealing especially with carrying out the overall policies and exerting financial audit.

Unlike the English management, the German one should be differently characterized depending on the hierarchical level. In the German firms, superior level management includes besides the members of the leading team (Directorship) also the executive staff, mention should be made that from the structural organization point of view, the organization structures on functions and division structures are very significant, displaying the following basic characteristics:

- at the superior level there is a numerous group of specialists who control the activity of firm's components, provide services to the organization subdivisions;

- the dominant organization structure is of horizontal type;

- the major decisions are usually taken in a participative way by the managerial team under the form of the managerial council;

Germany with France has registered after 1990 a revival of economies sustained mainly by the dynamics of investments and keeping the inflation under control. The German management plays in this sense an important part in: adjusting the relationships between management and trade unions in firms, under the conditions when the firms' management has to satisfy the needs imposed by trade unions in view of increasing competitiveness, training diversely managers under the condition when at different hierarchical levels of firms management there are more possibilities of getting a manager post, applying the partnership ideas included in the concept of social market economy.

The most remarkable characteristic of French context which strongly influences the firms' management is the state intervention in business by establishing the main directions of economic development and even by getting involved in some economic sectors which led to the obtaining of great results in different fields (for example in the production of high speed trains TGV, Mintel or in the aeronautic field Concorde Airbus). In principle, French management is different from the German one as the firms are structured on divisions or functions (management structures consists of numerous hierarchical levels); decisional centralization degree is higher than in Germany due to the tendency of the firm president or senior manager to monopolize the major decision-taking; the communication system functions heavily, especially at the inferior levels, fact which may affect the staff's moral condition.

As regards the Italian management one should have in view first that after the Second World War, Italy has become one of the most industrialized countries in the world. The management of Italian firms has been significantly influenced by the USA management model; the admiration for the results obtained by American companies is visible both in the expansion of business schools in Italy and the fact that a numerous Italian managers have got a MBA diploma. But we can not speak of the Italian

management without mentioning a few of its characteristics: [1]

- the management styles differ from each other because of the differences occurring between the three big categories of companies (the group of big private companies; holding companies, belonging to the state and small enterprises) functioning in the Italian context;

- regarding the managers' characterization the distinction should be made between those working in the state owned companies and those managing private owned companies;

- in formal relationships are predominant, ensuring maximum flexibility of managers in companies.

We can not end our incursion in the management systems used by the European countries, the most developed ones from the economic point of view, without bringing into discussion the Spanish management as well. Spain has known a spectacular development in the last 30 years, registering the highest rates of economic growth among the developed countries. The management diversity resides in the management style and different management techniques used in companies. The American and Japanese companies' performances present in Spain determined a new orientation also in the management field, by searching for new approaches which contribute to the increase of its efficiency.

As regards Romania there is an emerging need of carrying out a managerial know-how transfer fully adapted to the conditions of the economic development stage ran by our country at present, which basically requires a series of some demands: [2]

- to reduce as soon as possible the existing disparities as compared to the developed countries and to some ex communist ones which have registered lately sustained rhythms of economic growth , fact that allowed them to get integrated in the Euro-Atlantic structures;

- to create a politic, juridical and managerial well-settled framework which allow the development of a functional market economy;

- to increase economic performances and the population' s labor and life standard implicitly to the level registered in the European Union countries;

- to set up an electronic infrastructure capable of getting connected to the latest world networks.

Therefore, as a conclusion of the facts studied, we can appreciate that the management in European countries has specific characteristics from one country to another, regarding the managerial practices used; management structures in the companies, differentiated by the type of existing firms; cultural, social, economic diversity characterizing the European context. In Romania, at micro-economic level, it is necessary that a management of professional type should be provided which is specific to many Western countries by creating a national system of managers' training and perfecting, giving the leading functions to the persons skilled in the management field, extension of management counseling firms. In this way, an important role is devolved to the international transfer of managerial knowledge, having in view all the components of the management system referring to the introduction of some modern management methods and techniques used in other countries too, that should be accessible for the Romanian managers as well; the use of some efficient motivational systems, performing in other cultures but compatible with the traditions of our people.

3. Globalization of firms' activities

In view of getting the firm activity extended on the external market, a company may opt for one of the following five strategic alternatives of product adaptation and promotion under the existing conditions in other geographical regions: [5]

- direct extension of the product and communication means;
- direct adaptation of the product and communication means;
- adopting of the product on the external market and extension of communication means;
- adopting of communication means;
- discovery of the new product.

Direct extension supposes the product introduction on a foreign market in view of getting it profitable, without making direct changes of this one (in this case it is considered that all markets have the same characteristics). Another strategy has had

remarkable results in the case of photo cameras, we mention here the company Gillette which promoted its products by using the same advertising slogan at world level.

The second strategic alternative is by extending the product and adopting the communication means to the conditions of the external market. In this case, the same product may satisfy a new desire, being oriented towards a different market segment; the only change required refers to the choice of some advertising promotional means.

The third strategic alternative supposes the product to be adopted to the conditions of external market and expansion of communication means. This strategy is usually adopted by the companies promoting washing powders, by modifying the manufacture recipes accordingly to the local conditions and equipment used in washing, without including the communication means.

The fourth strategic alternative aims at both the product to be adopted and communication means as well. It is obvious that we talk about the companies trading their products in many different countries under different brands and using different marketing strategies. This is possible due to the existence of some management decentralized structures in companies within which the local managers can take decisions regarding both the product and the marketing activity.

The fifth strategic alternative is represented by *innovation*. In some cases an invention can be a more efficient solution than the extension or adopting of an existing product. We have in view here, as an innovative case considered as famous: the use of fuzzy programmes by the Japanese companies. Competition between companies has led to the technological "revolution". The utmost development of technics and technology has laid the bases of a protection type both competitive and "real" regarding the environment protection, the consumers' health and safety. In this sense, big transnational corporations had to create global standards for environment protection in order to avoid obstacles caused by regulations in the field already existing in some countries.

A strong effect of globalization has been felt on the financial markets which is a global dimension, the capital movement from one

area to another one determining the occurrence of some both economic and political crisis phenomena. To fight against these phenomena the governments are obliged to regulate the development conditions of global financial market.

The analysis of the position taken by the internationalization process is also interesting from the point of view of a company's general strategy. Globalization supposes extension of companies' businesses on other markets where the demand level is higher than the offer one. In this sense, companies have to adopt the manufacturing conditions to the existing ones at local level, enlarge the range of products and services, and to adapt its managerial culture to local companies. Carrying on activities abroad allows the new companies to render their own resources profitable.

As regards the companies' amplexness and functioning abroad we mention that the researcher Dunning analyzed and promoted a series of representative factors by the help of the paradigm O.L.I": [5]

- Factor O (Ownership Advantage) also called "competition capacity specific to the company" refers to the new products emerged on the market, the company's research and development capacity, the firms' specific know-how;

- Factor L (Location Advantage) states the regional advantages specific to the firm and quantifies globally the level of salaries in a certain area of interest for the firm, the corresponding infrastructure, political obstacles against the new investors, technological dynamics, and taxation system specific to that area.

- Factor I (International Advantage) is mainly focused on the transactional costs corresponding to the firm's own activities or those resulted from cooperation with third partner firms.

We specify that there is not a clear cut distinction between these factors, but there is a relationship of reciprocal dependence as follows: the factors specific to the firm (represented by the factor O) influence the local factor (represented by the factor L) as the investor promotes his own competition advantages abroad as well. The possible local disadvantages occurred (corresponding to the factor L) may be compensated by the reduction of transactional costs

(corresponding to the factor I). The main reasons which make the companies to extend their activity at global level refer to: [5]

- creation of a favorable framework for companies' development by increasing the sale volume, profit and market quota (the extension of companies' activities is made also by their penetration into certain external markets);

- rendering profitable the competition advantage the companies dispose of (for example the carrying on export activities increases the life cycle period of the companies' products , these ones beginning a new life cycle abroad);

- putting away competition by getting on the competitors' market.

In conclusion we can state that globalization allows the obtaining of advantages after having benefited from the synergy effects and economy especially by: getting the companies' managers concentrated on the most important activities; placing those less important activities out the company from the point of view of the company 's competitive advantage, thus having an optimized medium of the company's activities under conditions of high economic efficiency.

Global Managers' Role in Determining and Implementing the Firm Strategies

Băeșu Camelia
„Ștefan cel Mare” University of Suceava,
Faculty of Economics and Public Administration
cameliab@seap.usv.ro

Abstract

At present the most constant and decisive dimension of our society is represented by change, its effects the more significant are the shorter time they require. How do these changes influence precisely the managers in state companies and their managerial decisions? How have they succeeded in getting adapted to the emerging market economy?

A dominant characteristic of these changes is the transformation of the economies in the East European countries (ex communist) from controlled economies into free market ones being characterized by high offers of goods and services. The study on economic and political transformations in the East European countries highlights major differences between the strategies and instruments used in the transformation process and indicate the different social implications as well.

Key words: firm, managers, change, leadership

J.E.L. classification: M1, M10, M12

1. Introduction

Managers represent an extremely important competence of human resources in a firm, their contribution to establishing and reaching the firm's aims is – obviously- decisive. In the specialty literature the definitions of managers or leading framework given by notorious specialists differ, two of them being considered as principal. The first one includes in the category of managers not only the so-called managing staff but also specialized people; this is Peter Drucker's approach. The author states that “the

management is rendered obvious by the participation of human beings. Its task is to make people capable of performance, strong points efficient and their weaknesses irrelevant. This is all regarding management and this is the reason for which it is considered the critical determining factor.” [4] The second approach analyzes the functions fulfilled by managers within an organization and concludes that the sphere of competences, tasks and responsibilities borne by managers is larger than that of the executive staff.

Other specialists consider that the human resources manager should have, besides managerial knowledge and skills, the following qualities as well: [7]

- to be tenacious in pursuing the application of correct solutions;
- to be patient and comprehensive regarding the others' points of view and opinions;
- to do his best to improve and develop management methods used in his work and make the others sensitive to the human resources problem;
- to be able to find fast solutions for problems that might occur unexpectedly;
- to use the information and data resulting from previous studies in order to reduce useless work;
- to take care of people, get on with them, be an observer of human nature;
- to have teamwork spirit;
- to possess a strong loyalty sense towards the people he is working with and the firm as well;
- to be a good negotiator;
- to be good humour sensed and enthusiastic of his work.

2. The evolution of human resources management in Romania

In Romania, the communist period promoted a series of major changes in the management culture, of which knowledge is important to analyze the evolution of human resources management in firms. [1]

Managers' weak development of management capabilities is reflected by the lack of any vision on their own organization and their incapacity of making strategies and leading the firm to fulfill them;

The avoidance of bearing responsibilities towards the firm performances, bureaucratic obstructions and normative deficiencies become excuses of the own failure;

The importance of powerful relationships is even greater in our managerial environment than in other ones. Over time, it has led to a degradation of managers' authority as well as a distortion of the acknowledgement and appreciation pattern of personal value. Individual success has been completely eliminated for a long period of time from the common code of social appraisal, and the activity specific to managers has been regarded less like a profession and more like a social status, as a privileged position within the firm;

Instable management style. One of the observations made when discussing with foreign consultants is that the Romanian managers go very easily from a rigid attitude towards their subalterns to an excessively tolerant one. The polls made in this sense showed that the general style of management seems to be a democratic one, either consultative or participative.

The managers' reactions towards change are still confused. Although most managers admit that managerial innovation is important, they do not exclude the fact that there are a lot of obstacles against it, such as: lack of some managerial mentality, indolence, conservatism and the fear of inter-personal conflicts.

The correct understanding of relationships with market delays in taking place, the concern for products quality, as a condition of success, is still low, the direction to production predominating. Seriousness and responsibility in the relationships with partners are still underestimated, most managers not being

yet familiar with concepts such as "business ethics" or "social responsibility of the organization".

General self-didacticism of Romanian managers, the characteristic that shows that the Romanian manager trusts only in his own experience, capacity of overcoming critical situations, relying more on empirical knowledge and intuition than on the systematic acquisition and use of knowledge.

To develop the managerial capacities of present-day managers, a realistic program should sense the segmenting of target-collectivity and application of some adequate measures for each segment in part.

For top managers, great attention should be paid to the development of their managerial capacities, by means of some training programs, completed by consulting and assistance actions. The programs will focus on the integrating problems of the organization: strategic management, leadership, international business management, and business ethics. At the same time, the programs should train also the managers' abilities of working with people (communication, negotiation, motivation) as well as their personal abilities. A great part of these ones may be done by programs organized in the company framework.

For medium-level managers who operate in the functional departments of the firm, there is the possibility to organize medium-duration programs (approximately one or two weeks) focused mainly on: marketing (industrial marketing especially), development of human resources and quality assurance.

For inferior-level managers, it is necessary to organize programs that stimulate the development of personal abilities, train them in work team and offer them the organizing techniques required by this level.

In the managerial performance training, an important role is played by the idea exchange and experience provided by managers from the West as well as those from Eastern and Central Europe, facing the same types of problems, being made within some workshops and seminars, and which are real opportunities for the

Romanian managers to get directly into contact with what this profession involves at international level and at the same to improve their own abilities and knowledge.

Together with the global development of economy, the roles and tasks played by managers in corporations have also changed. Lately, in West economies, competition has focused on corporation strategies, but also on operational excellence, which are based on the promotion of department managers who know perfectly the firm and are capable of putting successfully their knowledge into practice. Therefore, at present, the success of a company depends decisively on *the managers' quality*. [3]

Although the specialty literature displays a lot of opinions regarding the factors that influence management efficiency, two of them catch significantly the attention, the strategic-economic vision expressed by Michael Porter, in the study *Competitive Advantage of Nations*, and that of managerial style, invoked by Peters and Waterman, in the study *Search of Excellence*, respectively.

Thus, Michael Porter in the study *Competitive Advantage of Nations* [8] considers that industrial profitability is determined essentially by five forces (suppliers, new competitors on the market, the existing competitors, buyers and replacements), which power differs from each other at the industrial level. The above mentioned author analyzes also the positions held by the firms which carry on their activities in the same industrial branches, specifying the generic strategies used by managers to obtain the competitive advantage. But the experience of these firms has shown that the generic strategies influenced the West managerial practice, as the managers were encouraged to develop one-dimensional strategies and neglected the role of operational excellence, as an important means of creating the competitive advantage.

Peters and Waterman in the study *In Search of Excellence*, [9] analyze the importance of the employees' motivation, managers' role and the functioning of a real feed-back at the organization level. Consequently, it is absolutely necessary for department managers to understand the

employees' role in carrying out the operational excellence.

The development of theory and practice in the field of human resources requires firstly greater comprehension of the role and particularities of human resources within organizations. Human resources are one of the most important investments of an organization, which results become more and more obvious over time. At present, the investment in people has proved to be the safest way to guarantee the survival of an organization or to ensure its competitiveness and future. [6]

3. Aspects regarding human resources management in welfare states

According to P. R. Lawrence and J. W. Lorsch's opinions, organizations need two types of managers: a *functional specialized* one and an *integrating* one, who ensure the synthesizing of different interests of the functional departments. In the view of this theory, three specific recruitment and promotion models of managers in the European context have been identified (The United Kingdom of Great Britain, Germany and France). [2]

The first model, specific to the United Kingdom of Great Britain, opts for decentralization of the management system and is characterized by the recruitment of managers from specialists in different functions of the organization (accountancy, production), paying less attention to their qualification as generalists having qualities as integrators at the company level.

The second model is specific to Germany and consists in the recruitment of managers from the range of functional specialists who are being trained throughout their career to acquire some skills that allow them to carry out integrator roles, required by the superior levels of organization management.

The third model, representative of France, is characterized by the fact that the functional manager's role and the integrating manager's one are never combined, the functional roles being played by medium-level and inferior-level managers, whereas the integrating

roles are performed by the top managers trained at Les Grandes Ecoles. In terms of the managerial training, French firms pay more and more importance to the candidates of manager positions who have got a MBA degree. Apart from their initial training in high schools and universities, in the French context great accent is laid on the managers' training within the companies where they may organize their own internal courses or appeal to specialized institutions such as trade chambers, consulting cabinets, private schools.

American managers' training in the field of management is made firstly in universities, then within the companies, before or after they have been hired, by special training programs. The most often encountered business diplomas are "major" and MBA, the latter one being considered the most wanted professional qualification, a performance of the four – year bachelor studies, followed by a specialization fifth year.

As for the Japanese management, according to some studies carried out, its main characteristics have been shaped as follows: [2]

- in large companies, having a labor market, the managers' promotion is made in the interior, most Japanese managers having a university diploma which allows them to ascend towards the hierarchy top;

- to occupy a manager position in the Japanese firms does not depend on the number of diplomas a person might have got but on the appurtenance to the respective company. Still, lately more and more Japanese people aim at obtaining a MBA abroad, maybe due to the development of some international activities carried on by the Japanese firms;

- the managers' promotion in the Japanese companies is made on the basis of seniority and long evaluation of their activities.

The management of Japanese firms pays great attention to the organizing of some training programs on the work spot, accompanied by the rotation systems of jobs, but also training programs outside the working place or even outside the company.

In the latter case, companies send their managers to specialized institutes in the country or abroad, to get knowledge in different fields important for the firm. By-mail courses are widely spread in Japan, some specialized bodies such as the Japanese School Management JSM, dedicating its whole activity to the organizing this type of courses.

The achievements in the field of managers' training are impressive, due to the Japanese firms' competitiveness, the most methods used being occidental, but adapted to the needs and requirements specific to the Cultural Japanese context.

Peter Drucker considers that tomorrow's manager is going to be not only an active person but also a thinker. According to this author's opinion, the future's manager should have at least the following characteristics: strategic thinking (to be able to combine analysis with intuition), intercultural competence (deep cultural knowledge of the country where the firm is), extensive and continuous training (should keep always the pace with the business and cultural novelties), personal standards and behavior standards (to fulfill professionally some personal standards, precise knowledge in business, responsibility, professionalism, continuous personal training and of the employees' as well). At the organization level, on the whole, the manager is the one who conceives and carries out complex strategies. Strategic thinking should include cooperation agreements with suppliers, buyers, customers and possible collaborators who should be regarded as a whole unit [5].

Concluding, we may state that when implementing their strategies, managers should take into consideration the internal economic environment and international one, where the firm carries on its activity, as well as the changes occurring in the consumers' preferences, in order to be able to apply a highly performing management, which ensures the reaching of the objectives aimed at under maximum profitability conditions.

Attracting Customer Banking and Quality Assurance Services and Banking Products

Bălăceanu Valeria Arina

Ecological University of Bucharest, Faculty of Economics Sciences

arina.balaceanu@gmail.com

Abstract

In the intense competitive conditions in order to ensure the required quality of services and financial products should be done to establish a standard of services and products and ensuring its maintenance. As such, an important part of the marketing process is to determine the minimum acceptable standards, such as for example, the maximum waiting time of a client.

Differentiation bank marketing was done essentially by modifying or supplementing concepts crystallized after long process that took place in terms of goods and services. Central axis of this differentiation is the content services and banking products, content to be the basis of specific marketing concepts but also of the market and consumer behavior. In most services, the obligations are unilateral while in the case of banking, both the client and the bank take their mutual obligations related to the use of a client of the bank's services.

Key words: Quality banking services and products, banks, bank marketing, consumers, customer segmentation

J.E.L. classifications: M31; G21

1. Introduction

Consumers choose what suits their needs. It is important that the banking financial institution to understand these needs and focus its services to clients who want to attract or provide services and/or banking products molded on their specific needs. Purchase intentions were outlined as important tool for forecasting demand for durable goods. The nature and content for the most part, banking services and financial products can be treated as durable goods.

The relationship between the client and banking financial institution is very important and needs to be maintained to ensure customer loyalty and develop long term relationships with them.

Quality products and services is now considered as a key factor of competitiveness of an organization in a specific market, including banks.

Banking competition is the determining factor that led to the need to implement modern management systems of customers because banks wanted to keep customers, they are a source of profit for banks and ultimately for shareholders, has contributed to a drastic change of philosophy from the bank product orientation to customer orientation with consequences both in business management and regulation at the systemic level in the banking sector.

2. Paper content

Analysis of customer behavior is a key component of marketing research. Customer is the most obvious barometer of the evolution of a bank. The presence of a number of increasingly more companies or individuals to bank tellers, confirms the quality of bank services, while others migrate to the same customers is testament to the weakness of the unit.

The challenge: customer orientation rather than product orientation caused significant mutations in the principles of customer segmentation. But, most banks are based on customer segmentation of the benefits they bring to the bank and not the complexity of their banking needs.

Most banks in Romania share the bank's customers in accordance with the strategy that establishes priority customer segments where the bank operates. Thus, these main categories can be identified by customers and

segments relating to each category: corporate banking; retail banking.

Each dividing the bank's main customer categories based on strategy, organizational form, the degree of evolution of customer management. Thus, we encounter segmentation using mainly the following criteria:

1. Criterion "turnover" - the criterion used in the segmentation of businesses due to high volumes of activity undertaken by these customers (generating significant income from interest and fees).

2. Criterion "Profit per customer" - often used criterion for segmenting international banks in both corporate clients and individuals.

3. Criterion "Volume of deposits" - especially segmentation criterion used in individuals. Customers with very high amount of resources are treated as VIP clients (private banking) and benefit from different treatment both in terms of banking products and services offered and their applied tariffs (significantly reduced compared to those of ordinary customers).

This segmentation does not yet lead to a separate serving customers in the segments, distribution channels and individual personnel, something which will be applied by the bank, through efficient management of customer relationships to achieve strategic and priority: *customer-oriented bank*.

When a bank customer to identify where money is not a problem, do all it can to attract and retain him. Fate in the privileged world have some special treatment, tailored to your bank account: *private banking*.

Technology facilitates the operations and transactions carried wrapped bank financial sector institutions. Today, all sectors of financial services shows increased pressure to cut profit margins. Opportunities arise constantly. To capitalize on these opportunities, institutions must adapt to new trends. It is hard to implement new techniques in an efficient, but once introduced to the organizations, the new method solves the problems encountered and the Internet specifically for each segment.

Private banking service is a luxury service to luxury customers. Customers who have in their accounts at least 100,000 euro may benefit from any such bank service offerings:

more favorable interest rates and fees on loans, product packages, cards that includes all kinds of facilities (including an insurance or some discounts) and the existence of a personal banker. The idea of a personal banker relies on the existence of a dedicated employee of that bank. The employee must also advise clients both in terms of ways to accumulate capital and in terms of ways to preserve its value. Customer will be advised not only in terms of the direction that should take the amounts invested, the bank will even say what share of capital it holds to be invested and the money placement tools are best.

Although a relatively new business in Romania, private banking already has many followers, especially those addressing the money. In principle, business people and allow a personal banker in order to multiply money. The number of Romanians who have a personal banker has increased by 25% over the past two years.

ING Bank Romania is estimated that approximately 50,000 potential clients for private banking services. Banks in Romania which have included in their financial activities such services are: ING Bank, HVB Bank, BCR, BRD, UniCredit, Raiffeisen Bank and Citibank.

The first operator on the market of private banking was ING Bank. The Bank has chosen to introduce such services to private asset management discovered an untapped market that at that time about 50,000 clients. ING currently has 500 such private banking clients who receive personalized counseling first, but also other advantages: negotiable interest on deposits, lending priority. For investment, these clients have individual deposits in lei and foreign currency, government securities, shares listed on the financial market in the country and abroad Eurobonds and municipal bonds.

Although private banking in Romania is a new concept, it exists in the group Societe Generale 100 years. Advisers to clients build customer assets depending on its objectives and global investment strategy. The group has branches in most remote areas of the globe: Tokyo, Hong Kong, Bahamas.

The supply of private banking that has earned its HVB Bank over 250 clients. Here Private Banking offers financial solutions for each client in addition to comprehensive and

personalized, a wide variety of investment options and information on financial instruments at his fingertips. Through this customer service HVB Bank may invest in: securities, BSE, RASDAQ, municipal bonds, Eurobonds, both at home and abroad. The private banking, and HVB Bank provides one stop support shop. This means that regardless of the financial needs of the customer claim, his application will always be satisfied or private banker.

In the case of banking services and financial products perceived risk is much bigger and more intense as the size of its formative elements take into account high-impact activities: intangibility more pronounced and total or partial loss of investment due to lack of liquidity or insolvency.

Give consumers greater confidence and important information from personal sources. Once found, information is retained more strongly and for longer, so that experience plays a more important role in learning.

The decision not to buy services highlight the discrepancy between perceived and desired level of consumer in the process of evaluation. Postponing the purchase decision may be due to reasons both endogenous and exogenous ones, which the company's marketing activity can alter and transform the actual purchase.

The decision to replace the service, in the context of brand loyalty may be due to a notable difference between the actual service delivered and perceived by the consumer.

And purchase intentions have emerged as an important tool of forecasting demand for durable goods. The nature and content for the most part, financial services, banking products can be treated as durable goods. Image as a representation of the meaning of customer service has in mind the most important place among the other dimensions being an element of consumer behavior customization of services.

Modeling consumer behavior bank financial services

Service on consumer behavior factors that act to customize the greater or lesser intensity of some of them. In the financial sector bank, an important place in the description of behavior of which shows influences separates

directly observable factors and the situational-specific marketing.

Marketing-specific factors are composed of mix components contained stimuli's. Mix's greater importance in services is determined by the character, specifically found in all its components.

Situational factors specific elements are made of when and where consumer behavior is manifested. Underlying the emergence of the need and the decision to purchase. Influences the nature of endogenous determine customer behavior to a greater extent, are specific psychological content and form of behavior. Helpful are considered: perception, information/learning/ personality, motivation and attitude. Usually, services are suggested by other more accurate presentation of the product components: environment, contact personnel, equipment.

Exogenous influences appear as non-personal sources of information, which is why they hold an important place in the formative factors of buying behavior. From this point of view separates variables: family, membership groups and reference groups. Peculiarities service consumer behavior may be seen by considering various factors which determine the size of the service, namely: the expected service and perceived service level.

The relationship between the client and banking financial institution is very important and needs to be maintained to ensure customer loyalty and develop long term relationships with them. Attracting new customers can be more expensive than maintaining existing ones. It is universally recognized that in a market economy, the price to attract new customers is 4 or 5 times in the financial cost and effort than developing and maintaining relationships with existing clients. Therefore, any financial institution, banking, fund maintenance of existing customers is a crucial part of marketing strategy. The strategy should contain a component which is directed at maintaining and developing this fund clients through meet their needs.

Customers, both current and prospective ones, are all important for economic activity, quality and customer care services, inevitably remain key elements of the total supply of services, but conditioned by the constraints imposed by controlling costs and maintaining competitiveness in terms of price. The key to

maintaining customer loyalty is to keep satisfied. If a customer is satisfied he will want to stay in relationship with the company, will use increasingly more services to meet their needs and recommend favorable bank and others.

Long-term loyal customers who will provide income to the bank. Customer loyalty improves the image of banks and financial institutions can be an excellent source of advertising. Customers attached, consisted not want to work with competitors of a company for similar services, even if sometimes they will offer cheaper services, or provide attractive interest rates.

Quality products and services is now considered as a determinant of competitiveness of an organization in a specific market, including banks. Together with other factors, quality products and services that determine quality environment and quality of life of every citizen.

In a bank customer relationship management resources are focused predominantly bank customers with a high degree of complexity requirements. Delivery of services and products, their structure, pricing, promotions be made according to customers' real needs. Also, the time you allocate the customer's bank is directly proportional to the degree of complexity (sophistication) of its activity.

Implementing a customer management system in a commercial bank behavior and completion of certain phases of the fulfillment of certain requirements such as:

- development and implementation of appropriate strategies - changing banking strategy and policies by which this applies is the first measure to be applied by each bank to be created within the overall implementation of the system of customer relationship management.
- customer segmentation process and understanding the needs of each customer segment in order to allocate appropriate resources, reduce costs, increase revenue;
- high degree of involvement of the bank's leadership in coordinating and organizing the project. It will organize a project team which will exclusively allocated resources to achieve project.
- defining technologies needed to implement - deciding which technology to be integrated into the new organizational

concept and is also a useful tool used in both business management and the basis for the decision is extremely important.

- choosing an IT partner and a reliable consultant - technology solutions provider credibility, experience in the marketplace, the ability to build a long term partnership will be the main issues considered at its selection;
- technological solutions will have to take into account the system's ability to provide applications for all business requirements and be sufficiently flexible for further development.

Thus, one can say that they bring together all the pieces of gear that will have a significant impact on profits and thus value of the bank shareholders. *Need for this management system is only due to the desire to obtain a higher profit per customer?* No. There are other equally important aspects that determine the necessity of implementing customer relationship management, business management as follows:

- implement a system must lead to obtain long-term performance and not short term. Such a system can only be done in an organization focused on creating partnerships with our clients on the proper understanding of their needs and their evolution in time;
- changing philosophy of approaching banks from product orientation to customer orientation has led to policy changes that require a bank customer relationship management efficiency for understanding customer needs;
- new banking regulations amplify the need for closely monitoring customer performance, the risk associated with selling bank products and services leading to additional data requirements and complex and detailed information about customers;
- banking process automation and distribution channel diversification generates additional needs of management and integration of information and data about customers;
- IT solutions are becoming increasingly complex and causes continual change in business rules that impact directly on business bank customer relations management;

- retain customers in the system is an important factor for the profitability of banks;
- retain customers is even greater as the number of products and services sold to one customer is higher;
- achieve a high degree of retention involves complex and integrated management of all distribution channels and achieve a single database that integrates data and customer information from all these channels of distribution.

Banking competition is the determining factor that led to the need to implement modern management systems of customers because banks wanted to keep customers, they are a source of profit for banks and ultimately for shareholders, has contributed to a drastic change of philosophy from the bank product orientation to customer orientation with consequences both in business management and regulation at the systemic level in the banking sector.

Providing quality banking products and services

Quality banking services and products is difficult to define because it has few natural size. Studies indicate that only a measure of quality banking products and services is the opposite of the perception of customers that product. Customer attitudes towards banking service that is formed according to the discrepancy that exists between their expectations and actual service performance. Therefore, in promoting their services to banks should be guided by the motto "***Promise only what you give and give more than you promised***".

Consumer banking products and services should not be misled by advertising. Realistic expectations must be built, because customers may be dissatisfied and can give excellent services or products because of advertising which has generated the expected levels without real support.

Referring to our banking system, quality banking services and products is shown by indicators calculated on the basis of the reports of the prudential and reporting of financial accounting. These indicators have worsened lately noted, the main explanations are: the economic recession and rising unemployment, currency depreciation in early 2009 (given that the relevant issue

foreign currency loans accumulate about 60% of government credit) financial disintermediation, high level of interest on loans, risks related to the growing trend.

Negative trend that we recorded quality loan portfolio, the effect of global economic recession and financial crisis, common to many developed and emerging countries in the European Union. A positive aspect is that if our country in the balance sheets of credit institutions do not exist "*toxic assets*" (toxic assets = popular term for certain financial assets whose value has dropped significantly and there is not a market functional, so that such assets can not be sold at a price satisfactory to the holder. The term became common during the 2007-2010 financial crisis, in which he played a major role, but also that no bank was not in bankruptcy. Thus, there was no need for government intervention, namely the use of public money to rescue banks.

The main purpose and, moreover, customer loyalty is the key to maintaining a high degree of customer satisfaction. S has shown that once a customer has chosen a bank, it is unlikely that will change if it is satisfied with the services offered. On the other hand, a satisfied and happy customer will recommend the service to others. Maintaining customers is much less expensive than attracting new customers. To keep a bank customer must always come to meet their needs, must reach the "***threshold of customer reaction***". Each bank aware of the importance of quality services aspire to exceed a minimum level of satisfaction and provide customers more than they require.

It is important for those in charge of marketing in the bank to know if consumers hold favorable or unfavorable attitudes towards products/services them and understand why clients have these attitudes.

The priority objectives for efficient management of total quality banking products and services, according to our concept, have in mind:

- anticipating needs, expectations and needs of individual clients and providing customized solutions able to satisfy all these requirements, expectations and needs;
- primary orientation towards the client, but also taking into account the

needs, requirements and expectations of other stakeholders;

- total commitment to quality by all managers and employees;
- providing services and products of the highest quality;
- establish relationships with the best customer loyalty;
- providing the necessary skills, motivation and involvement of all employees;
- providing integrated services for clients.

The implementation of quality, an important element of success is the clear vision of management and its ability to transfer his enthusiasm to all bank employees.

For any bank, it is vital that services and products they offer to be successfully listed on the market to achieve the objectives of growth and development of bank and financial sector default bank. Relationship between client and bank is very important and needs to be maintained to ensure loyalty and to develop longer term relationships with them.

Service quality is the result of confirmation of consumer expectations that they have experienced during rendering. Banking service quality depends on the knowledge of the person providing the service, her skills, motivation, good will and personality, but also the perception that receives customer service.

Banking institutions can provide quality control by offering various ways: selecting the best personnel and providing effective training and his being caught; monitoring (inventory) customer satisfaction by monitoring their behavior and setting any suggestions or complaints procedures and ensure that distribution methods to present a consistent and acceptable level of service.

3. Conclusions

Improved activity in the future - if the service quality standards are set correctly and monitored properly, they will constitute an effective mechanism for planning future improvements and developments of financial products and services.

Monitoring standards of performance are vital strategies for successful customer loyalty through quality service and products. Thus, checks can be:

- *Internal* - held in the branch and the Central in order to confirm the application and system performance standards;
- *external* - are aimed at ensuring the manner in which customers are satisfied with the quality of service.

Measuring instruments used are different, one of the techniques commonly used in the financial system is that of „*mystery customer*”.

Quality management perspective banking is extremely interesting, considering the character, but demand and supply dynamics of banking services and products, and continuous emphasis on competition. Increasing the number of banks has led to the development of competition and awareness of issues related to quality banking services and products offered on the market (so to consider the quality perceived by the customer, not just the desired quality/made by banking institution).

Increasing the number of banks has led to the development of competition and awareness of issues related to quality banking services and products offered on the market (so to consider the quality perceived by the customer, not just the desired quality/made by banking institution).

Banking and Financial Markets in the New Economy. Impact of the Financial Institutions Banking

Bălăceanu Valeria Arina

Ecological University of Bucharest, Faculty of Economics Sciences

arina.balaceanu@gmail.com

Abstract

Use of new technologies and how the circulation of information, in banking, globalization emphasizes more than any other field. Today, globalization of financial markets is a priority both for multinational companies and governments and international institutions. The degree of priority is determined by financial markets ensure that the entire global economy connection.

Financial crisis calls into question the situation of areas (components) of the capital markets less regulated and controlled (the mortgage market, derivatives market etc.). One clear effect that it has the financial crisis is the rethinking and reforming financial systems by introducing new measurement systems and financial risk assessment but also by exerting greater control by regulatory institutions in the investment funds, pension funds funds, life insurance and mortgage.

Key words: financial markets, financial systems, new economy, knowledge economy, globalization

J.E.L. classifications: G2; G3

In the new economy - knowledge-based economy, individuals are more important than local in which they were grouped according to traditional theories of segmentation (segments defined by nationality, income, age). Evolution of the main financial markets lead in future to build a global integrated financial market dominated by global financial conglomerates activity that will develop around the existing banks. Global financial market will be characterized by a market-based system, because this system does not require legislation in detail all aspects of transactions

in financial products and services and is one that facilitates the process of innovation.

Currently there are a lot of *obstacles* that must be overcome in order to speak truly a global financial market. These include:

- of lack of harmonized accounting regulations that determine a company's financial reporting standards in different countries. This standardization should allow an easy analysis of the financial situation of companies in which it invests. To overcome this obstacle, so the European Commission and International Monetary Fund have established international standards and a code of conduct applicable at international level.
- the principles of corporate governance failure and treatment of minority investors, particularly in developing countries.
- insufficient development of infrastructure to enable the achievement of an important obstacle for International Settlements, whose desire to overcome not only depend on regulatory and control authorities of financial markets, but also the financial resources allocated.

The existence of obstacles mentioned represents a normal situation, but will not be unavoidable, so long as globalization is a necessity of the evolution of human society, society has reached a level of development that makes it extremely difficult if not impossible to exist in the space closed, without relations with the outside.

When a company is not working well, economically, one of the first measures is to reduce the marketing budget. But in a crisis that affects or may affect financial increasingly more banks, communication strategies should be improved and piled upon the current and far from reducing marketing

budgets. The funds for what is marketing is extremely important as how they are promoted and distributed bank products and services, contribute to profits.

After that included the U.S. financial crisis spread to Europe, affecting the banking system. Information about the bankruptcy of Lehman Brothers, the fourth-largest investment bank in the U.S. in size, the front page of the international media. **The crisis over the ocean, prompting authorities in Europe to generate reactions and management welcome the effects.**

However, before being a general financial crisis, the current situation should be individualized in terms of communication, the main problem of each banking institution. At least for current and correct information to clients to keep control of an outbreak of general panic, each banking institution would need to communicate effectively and to inform their customers about the situation they face. We are not referring here to new strategies for positioning or integrated communication campaigns for various services but the information on strict financial crisis.

Financial crisis situation raises the issue of those areas (components) of the stock market less regulated and controlled (the mortgage market, derivatives market etc.). The effect that you submit financial crisis lies in rethinking and reform of financial systems by introducing new measurement systems and financial risk assessment but also by exerting greater control by regulatory institutions in the investment funds, pension funds, life insurance funds and mortgage.

Bank financial institutions that have experienced unwanted effects of financial crisis or have been declared bankrupt, or were withdrawn from trading on the stock is then partially or wholly taken over by other banks or groups of banks.

Fingerprints on the financial crisis has left them on the financial institutions can be summarized as follows:

1. Financial institutions supported, monitored or taken by the government:

- **Northern Rock** (nationalized)
- **IndyMac Federal Bank** (under the supervision of the Federal Deposit Insurance Corporation);
- **Fannie Mae** (taken by the government);
- **Freddie Mac** (taken by the government);

- **American International Group** (in September 2008 received a credit facility from the government worth 85 billion dollars guaranteed 80% of its shares);
- **Bradford & Bingley** (nationalized in part on September 29, 2008 and partially sold to Spanish bank group bank Abbey Grupo Santander);
- **Fortis** (Belgian government took over in October 5th, 2008 and will be finalized its sale to BNP Paribas);
- **Glitnir** (Icelandic government bought by Icelandic Financial Supervisory Authority on September 29, 2008 for \$ 600 million Euro);
- **Hypo Real Estate** (received approval on 29 September 2008 for a credit line worth 35 billion euros from the German government and a group of banks, then on October 4 it was agreed that this credit line will be worth 30 billion euros from banks and groups of 20 billion euros from the Bundesbank);
- **Dexia** (on September 30, 2008 the Belgian, French and Luxembourg announced a 20.4 billion-funded banks that Euro);
- **Landsbanki** (located since October 7, 2008 under government surveillance Icelandic Financial Supervisory Authority in Iceland);
- **Kaupthing** (suspended from trading on October 8, 2008 and placed under government surveillance Icelandic Financial Supervisory Authority in Iceland);
- **ING Group** (received on October 19, 2008 10 billion Euro funding from Dutch government);
- **Citigroup** (on November 24, 2008 received funds amounting to 25 billion dollars plus the 20 billion dollars received in October 2008, the market value of its shares dropping significantly to 244 billion dollars to 21 billion USD, a decrease almost 10 times).

2. Financial institutions bought/taken the market by other financial institutions:

- **Countrywide Financial** (acquired by Bank of America with 4.1 billion dollars on January 11, 2008);
- **Bear Stearns** (taken over by JP Morgan Chase in March 2008 after previously received a loan from the U.S. government);

- **Alliance & Leicester** (taken in October 2008 after Spanish bank Banco Santander has been delisted from the London Stock Exchange in June 2008);
- **Merrill Lynch** (acquired by Bank of America);
- **Washington Mutual** (partially sold to JP Morgan Chase for 1.9 billion dollars in June 2008, the rest going into bankruptcy);
- **HBOS** (in January 2009 became part of the bank group Lloyds Banking Group);
- **Lehman Brothers** (partially sold to Barclays and Nomura Holdings plc, partially declared bankrupt);
- **Wachovia Corporation** (will be acquired by Wells Fargo for \$ 15.1 billion dollars already approved the merger with the Federal Reserve);
- **Sovereign Bank** (Banco Santander bought for \$ 1.9 billion USD on October 13, 2008);
- **National City Corp** (acquired by PNC Financial Services on October 24 for \$ 5.2 billion USD with support from U.S. government).

3. Institutions declared bankrupt:

- **New Century Financial Corporation**
 - **American Freedom Mortgage**
 - **American Home Mortgage**
 - **Lehman Brothers** (partially sold to Barclays and Nomura Holdings)
 - **NetBank** (american bank)
 - **Terra Securities** (Norwegian company specializing in selling various financial instruments);
 - **Sentinel Management Group** (american financial services company specializing in cash management);
 - **Washington Mutual** (investment fund partially sold to JP Morgan Chase);
 - **Icesave** (savings bank Landsbanki Group)
 - **Kaupthing Singer & Friedlander** (British bank partly transferred to ING Group, went bankrupt partly)
 - **Yamato Life** (Japanese insurance company went bankrupt on October 10, 2008)

4. Institutions in reorganization procedure:

- **ACC Capital Holdings** (American savings bank specializing in mortgage loans).

All these mutations on the capital market, have caused significant international changes both in the evolution of capital market (volume, volatility) and the perception and behavior of individual and institutional investors.

Financial crisis caused a shift in the objectives of the banks, mainly from the quantitative targets (to increase market share or maximizing profits in the short term) by line approach to reduce the financial intermediation process globally, which accommodates most significant measure in a qualitative analysis and risk associated with lending. Reducing the supply of financing from Romanian banks has resulted in tighter lending standards and terms of population and companies. Tightening was more severe than in the euro area (both in intensity and the speed of implementation). Romanian banks have argued these measures through: negative expectations regarding general economic situation; high risk associated with high duration and price adjustments necessary for the execution of collateral/security required; growing risk associated with some companies operating in sectors; expectations on the deteriorating financial situation of the population.

Which banks and lending terms have tightened the most in 2009 were: the average interest rate margin over ROBOR (for loans to businesses and households), collateral requirements (for credit companies) and the maximum weight of debt service in monthly income (for crediting the population). Yet even amid the pressures on financial intermediation, there are market segments that have seen positive developments in terms of financing:

(A) loans to corporations, especially

(B) real estate loans for the population (increase of 22 percent, in December 2008 - June 2010).

The fact that the Romanian banking system has escaped unharmed from the present crisis does not mean he has to face some major challenges. Of these, we mention those of which we have found most important:

1. rigorous and responsible assessment of the risks of banking activity by: avoid exuberance that could trigger a fact that has not spread in our banking crisis; clear understanding of the fact that Romania has not yet come a full economic cycle. The fact that the economy is in expansion phase of a great help maintain healthy banking system. In assessing risk, but banks need to take into consideration the time when economic growth will not be as robust; avoid the illusion that any risk assumed by the bank may be transferred to the customer. Excessive risks can easily be turned against the creditor; maintain vigilance to minimize operational risk. Strong growth in customers and transactions, increasing the number of units and employees are, by themselves, operational risk factors that must be evaluated and countered by appropriate measures.

2. Rigorous preparation for labor. It is closely related to minimizing operational risk. Often, unfortunately, but just sacrificing austerity programs of staff training budgets - which affects a company's potential long-term. Especially so in a dynamic industry such as banking industry, where the workforce has increased by ten percent every year, and global market conditions are in so deep a transformation, continuous training of staff is a prerequisite.

Why is it less vulnerable banking system in Romania? Explanation:

- strong capital base: until a few years ago, he could even speak of an over cap, most banks recorded solvency ratio well above the limits recommended by the Basel standards.
- the investments are domestic, which is booming.
- the statement that the banking system from us was not affected by the crisis because it is unjust primitive. Investments in domestic loans provide a high efficiency, which is superfluous seeking other investments on foreign markets. The problems in our banks are to identify new resources, internal and external, and maintain portfolio health officer.
- the new regulations of the National Bank for credit slowdown can contribute to maintaining a healthy loan portfolio.

- if they could see a temporary additional liquidity needs, the first resource should be even reserve requirements of banks at the NBR, which is a very valuable safety net for times of tension.

Starting from the above analysis we tried to sketch: **STRENGTHS-WEAKNESSES** Romanian banking system, which could be considered a starting point for the separation of assumptions about future developments in Romania's banking activity.

What we want to emphasize is that the banking industry is a special, in which trust is the key to proper functioning of the banking system. Once lost that trust, even in terms of performance of banking institutions, everything collapses.

STRENGTHS, without rank them in importance:

- Romanian minimum reserves banks hold significant central bank, until recently 20% of deposits in RON (currently 18%), and for those currency reserve rate is 40% at present. This demonstrates that the central bank has enough cash available to the system could gradually pump in case of liquidity crisis (which he did by cutting rates by 2% to the RON).
- Prudence and profitability indicators for 2008, though deteriorated slightly from last year show that the Romanian banking system is strong.
- Starting October 15, 2008, the coverage level per depositor per institution to guarantee individual and increased credit to the RON equivalent of EUR 50,000, while guaranteeing coverage per depositor per institution legal person and guaranteed credit remained same level, equivalent in lei at 20,000 euros. Even with a ceiling of 20,000 euros of deposits were covered 99.2%, meaning 60% of the total value of the total deposits in the system.
- The new lending rules have reduced appetite for lending of the Romans, by the fact that banks were forced to become more restrictive in lending, starting with their first clients.
- BNR's foreign currency reserve is a consistent (from 1 October 2008 as 26 billion euros), is always ready, when

- need requires, to be thrown into the market to calm everyone down.
- Central bank communication policy is an increasingly more active government working with the governor and the presidency in the transmission of messages to the public.
 - There is a fruitful working relationship between BNR and lately the Romanian Association of Banks.
 - Credit Bureau activity has intensified, there is evidence of an increasingly comprehensive borrowers.
 - Romanian banks have so far invested in "toxic", especially on the European market.
 - The possibilities of growth and development of our country can continue to attract foreign investors eager to invest better.
- A possible resetting of real estate prices (depending on its magnitude), which could affect the real estate collateral. However, the share of mortgage loans is only 3.8% of GDP, very low levels compared with Western countries;
 - The possibility of bankruptcy of some foreign banks which have branches or acquisitions in Romania;
 - Due to the liquidity crisis from abroad, some parent banks will pump more money in subsidiaries in Romania.

Existing banking crisis several years ago showed that the risk of rumor is most important in Romania than its market rate risk. Customer bank had to learn to choose their banks, not only by interest rate subsidies, charges and variety of savings instruments offered, but also by the degree of transparency of the banking institution, savings safety is paramount.

In 2011 the bank expects profit discounts that may mean, in fact, a reasonable approximation. Banks in Romania you definitely have a serious signal that it takes more than common sense in dealing with clients. If in 2011 the banks will start to fight for every dollar, and may not be so bad for customers, at least in certain respects.

Looking ahead, the development of the Romanian banking system has **SEVERAL DIRECTIONS** in which forecasts and other **DEVELOPMENTS MAY BE LESS CERTAIN.**

Between the forecasts score significantly reduce bank intermediation costs. Another area where other reducing intermediation costs will be highlighted in the next period is that of population deposits. The contribution of commercial banks for establishment and operation of the guarantee fund then deposits in the banking system was substantial. This fund and created a significant resource, which will allow the lifting of ceilings on the level of coverage to Europe.

In category developments enroll less certain number of banks which will operate in Romania between 2010-2014. In regard to the number of banks in Romania during 2014 (when it was hoped that it will adopt the euro), it will be the result of complex processes that do not last, will play an important role both on the banking market competition, and policy major market players

WEAKNESSES:

- Approximately 57% of foreign currency loans are granted, making it sensitive to exchange rate variations banks portfolio;
- A series of macroeconomic indicators have a tendency to deterioration, which may cause instability in the external capital flows;
- The largest bank in the system, BCR has been relegated by Standard & Poor's from BBB to BB+, the trend can be maintained for other banks;
- Concentration of banking activity in Romania, though declining, is quite high in June 2008, the first five banks in the system focused more than 50% of total bank assets, of which the first two, BCR and BRD-GSG, owned 37,2% of total assets;
- International situation, especially developments in currency markets in the region are vulnerable to Romania, especially in terms of speculative attacks;
- The public loses confidence in the banking system, due to the unethical behavior of some banks, especially during the current, tense (irregular raises interest and fees etc.);
- The existence of banking products and promotional variable interest then that could affect the ability of future redeemability customers.

on their local network development and credit profile.

Romania's banking system development in future will depend on successful completion of stages as a priority, as follows: permanent adaptation of banking legislation and aligning it with EU legislation and to remove legal ambiguities which obstruct the central bank supervisory capacity; strengthening regulation and supervision of capital markets, improve the quality of information about companies listed on BVB and RASDAQ, foreign investors including portfolio investors; National Bank continues to focus on well-designed prudential regulations that provide safety and stimulation, including a revised set of capital rules, the review of the pricing scheme of deposit insurance, focusing on different functional regulation of financial institutions; focus on capital market development by inviting renowned international rating agencies and brokerage houses to participate more actively in the market and by providing more stringent transparency requirements; setting up a government agency to facilitate the development of a secondary mortgage market; continue the process of developing more stringent insurance regulations.

Priorities: invite international rating agencies and brokerage firms with experience in evaluating companies will act to further the activities of rating agencies in Romania; acceleration of industrial restructuring and investment in infrastructure to create new opportunities for insurance companies; correcting regional economic imbalances; strengthening relations with international banks and financial institutions access to external financing on favorable terms.

One of the main challenges for banks in the current situation in Romania regarding the deepening international crisis of liquidity, is the limit, but also more expensive external financing sources, affecting the degree of expansion of their restraint. Although acute lack of liquidity, lending will continue to grow corporate business and retail, even if the pace of increase will be lower, due to the change in market conditions. On retail lending will maintain a high growth rate, compared to the corporate clients because of high demand, especially on consumer credit and mortgage. Also, new lending restrictions

imposed by the BNR are absolutely necessary to maintain financial stability in Romania, considering the lack of liquidity but the existence of international and national.

Even if they find that banks are turning increasingly toward the retail market segments where the offer is meant to be more appealing to the novel that he wants a house, a car, a holiday abroad or any other personal need fulfillment strategies bank still go fine on the corporate segment, where business networking, negotiation and customer culture is situated at higher levels.

Essential for a bank's credit policy is to maintain a balance of retail and corporate clients in the area according to their contribution to obtaining a commercial bank profits and a balanced and efficient management of assets and liabilities.

The measures in finance, both regulatory and non regulatory nature they are based on four main objectives: to strengthen market transparency, especially regarding the operations of banks' exposure to financial disintermediation and their commitments outside the balance sheet; improve assessment procedures to respond, in particular, problems arising from the evaluation of illiquid assets, strengthening the EU prudential framework for banking, for example how to deal with major risks, banks' exposure to titrizare operations and liquidity risk management, examining various issues concerning the role of rating agencies.

Unemployment, a Phenomenon of Global Imbalance. The Evolution in Romania in the Last 20 Years

Bălan Ana Maria
„Alexandru Ioan Cuza” University of Iasi
balan_ana84@yahoo.com

Abstract

Unemployment is one of the negative phenomenon which occur with great intensity during the transition. It is encountered in any economy; in our country, the unemployment have reached high proportions.

As a global macro-flow, unemployment is generated by cases dealing with the economic situation of users, on the one hand, and social status of job bidders, on the other side.

The purpose of this article is to highlight the features of unemployment, the phenomenon existing in any global economy; also the paper aims to reveal the indicators that characterize this phenomenon, for example in Romania. Unemployment had became now, after 90 years', an important phenomenon of Romanian society and economy. Following the privatizations of the years after the revolution and restructuring of the industry, had been created a large imbalance between supply and demand of jobs.

Key words: unemployment, policies, measurement indicators, imbalance, unemployment rate.

J.E.L. classification: E24, J6, J21.

1. Introduction

Through the alarming extent and its complex structures, but especially through the dynamics that change the rhythms and meanings, unemployment has become a macroeconomic problem, being the subject of fierce theoretical, methodological and political-ideological disputes

Unemployment is considered the natural phenomenon that always accompanies the economic and social development process of each country.

In the normal range of about 3-4% and relatively short-duration, the unemployment, according to opinion of experts, can play a positive role, both globally and individually, to stimulate the employment factor's flexibility, to enhance the productivity to stimulate the education and to improve labor discipline.

2. Conceptualizing the unemployment, through causes and effects

Unemployment is analyzed in the literature from several perspectives, with more kind of views expressed, often controversial; along the way have been offered numerous definitions of this concept, which, although characterized by diversity, yet they contain common elements. The word "unemployment" has its origins in the french "chômage", which derives from the latin "caumare. The Latin word comes from the greek "cauma" which refer to "high heat" which stoped any activity.

Samuleson defines the unemployment as "a plague of modern economies which prevent people to work." Milton Friedman argues that unemployment is useful and justified as a "natural consequence of market mechanism". Băbeanu Marin and others from Romanian literature [2] consider unemployment "a concept that means the opposite situation of employment of labor resources, it represents the degree of vacancy of potentially active population who would like to work, but can not find a job".

The french professor Alain Cotta described unemployment as "the situation of the no working individual ", considering that only the involuntary unemployment must be taken into account in analyzing the country's economic situation". A belgian professor, Fernard Baudhuin sees unemployment as "full or partial inactivity of a group or of an individual" [4].

Unemployment is linked with various types of economic, demographic and socio-cultural behaviors, with the skills of the workforce, productivity, technological progress, economic development or recession etc. [5]. There are many reasons that cause unemployment, both at micro and macro level [1]. A major cause is the insufficient demand for labor, the state of inactivity being the subjective desire of those concerned or determined by factors beyond their control.

Among the possible causes of this phenomenon are reminded:

- the natural growth of labor resources, namely the working age population;
- the slow development of private sector;
- the disposal of a employed population part, as a result of jobs' reclassification;
- the specialization and segmentation of social - professional non-competing groups and categories, as a result of the unprecedented multiplication of jobs, specializations and qualifications and of the many differences between employees, in terms of their experience and ability;
- the enhancing of interventionism elements from public power or institutions involved in training staff, hiring or using the work factor, with impact on the labor market.

The negative effects of unemployment can be viewed both socially and economically, in other words, are the effects felt by the unemployed and his family and effects at the macroeconomic level. Unemployment is a personal issue that affects the dignity, and sometimes the balance of the persons concerned, causing tensions in family life. On the other hand, unemployment can lead to an increase in violence, crime, delinquency, due to the low standard of living of the unemployed.

At the macroeconomic level, the unemployment causes a significant decrease for part of labor resources, which leads to lower intensity of economic development, but also to increased costs required to support the economy as unemployment benefits.

Specifically, when discusses about the consequences of such an imbalance, are taken into account those:

- the phenomenon induces itself the notion of poverty because is causing the sharp decline in living standards and the quality of living;
- are affected the individuals who are part of the active population underemployed, people who have the desire and ability to work, but have no place to work;
- being a macroeconomic imbalance, it not affects only the materials departments of the national economy, but also its human elements;
- is developed the work on the black market, usually with lower pay, under the national minimum wage prices and without employment contract;
- the redundancies represent a powerful obstacle to a country's economic recovery activities.

Some prospects remark positive consequences of unemployment, such as:

- if is assumed that usually are dismissed the least prepared people or those with low skills, appears the raising interest for work, but especially is enhancing the competitiveness of existing workers (psychological impact);
- because it is the following of the individuals dismissal, this phenomenon creates a backup (not necessarily safe) of people potentially willing to work, in the idea to cover a possible additional demand for labor;
- for employed people, is influenced their discipline and punctuality, because of the risk of dismissal.

3. The evolution of unemployment in Romania after 1991

The long-term unemployment in Romania has increased both, in absolute and relative terms, in the recent years, leading to increased the expenditure, concerning the unemployment benefits - to support allowance and social assistance programs for the unemployed labor force [3].

The existence of unemployment in Romania has manifested itself in the first part of the twentieth century, but its size was reduced in numbers, because the industry used a low share of urban working population (the urban population was 3,051,253 in 1930 and until 1948 reached

3,713,139 persons). The statistics show that the number of unemployed in Romania grew in the first half of the century, arriving in 1928 to 32,727 people (in a population of about 17 million), in 1932 to 38,890 people (in a population of 18,426,159 people) and in 1937 the number of unemployed fell to 10,851 people (from 19,535,398 inhabitants)

During the Second World War, in Romania was introduced the Law on labor during the war; therefore, the economic crisis took acute forms, which led in political and legal plan to the forced abolition of unemployment. The lack of unemployment during the Law in wartime has non-economic causes.

After the war period until 1989, the withholding of unemployment in Romania has special explanations, closely related to the increase (accelerated) in industrial economic, to the massive urbanization (agglomeration of population in cities) and to construction of national economic objectives, integrated in a centralized strategy of using the resources.

This does not exclude the existence in Romania of possible forms of disguised unemployment.

Effectively, the manifestation of this phenomenon takes place since 1989 in a very fast pace, its share increasing by 2-3% per year. Now take place a division in economy, unfurled amid privatization and economic activities' decentralization, which targeted mainly trade, transport, communications and computerization activities in general rather than service sector of industrial production.

During the 19 years of transition, the size, dynamics, shape and characteristics of unemployment in our country have evolved and have qualified.

After 1990, the labor market in Romania has caused tension, determined, first, by the ownership, the development of market economy and the changing relationship between supply and demand, and on the other hand, by the dynamics of the socio-demographics structures (age, demographic relationship dependency unfavorable etc.).

At that time, training and labor market performance has become a priority of its economic reform program. Since February 1991, was introduced the unemployment aid, as a form of social protection and represent all the measures taken to prevent, remove or

decrease the consequences of certain "social risks" on the living standards of the population. In fact, social protection is a form of insurance to individuals against the risk of loss of revenue [7].

After 1991, when Romania was enacted Law no. 1 concerning the social protection of unemployed and their reintegration in work, unemployment has become the main form of labor market imbalance.

4. Anti-unemployment policies and measurement indicators – past and actuality in Romania

The policies for combating unemployment aimed to encourage employees to turn to growing areas branches, to fields for which exist demand on the labor market. Gheorghe Oprea (2001) proposes a series of measures that may result in policies to combat the unemployment:

- policies to support the economic growth process: they are necessary, since it is accepted that one of the main causes of unemployment (especially the cycle form) is the insufficient concern for visible growth. The decisive role, from this perspective - is detained by state, which, through financial, monetary and fiscal mechanisms, must spur the real overall progress, ensuring proper conditions for a moderne market economy development ;
- policies to reduce the labor supply: concerns the older employees, whose rate of activity in countries in transition, although decreasing, is higher than in developed countries;
- services for unemployed: the improving and the expanding of services offered by the labor offices can not be neglected. In Western Europe, for example, are 7 to 14 workers in such institutions to 10 000 people, while in Eastern Europe are 1-2 workers for the same number of working age people;
- creation of new jobs: it is justified especially in terms of efficiency and is not recommended a forced or arbitrary increasing for labor demand;
- general measures on labor market factors, suppose: the external flexibility- in order to adapt the number of workers to the

demand changes for labor (through moderate layoffs); the internal flexibility, through resizing working time; the restructuring of technological processes manufacturing;

- training / retraining: when carrying out restructuring, not only redundant workers lose jobs, but there is no demand for what they provide. Retraining is very important, especially if there is a situation that the number of vacancies is equal to the number of unemployed, and lack of qualification would prevent the latter to become employees [6].

A good employment policy should cover not only reduce unemployment but also precarious employment restrictions for the creation of stable and well paid jobs [8].

The unemployed population: is formed by unemployed persons looking for another job or people seeking their first job, people aged 15-74 years, which, according to the International Labour Office, must meet the following conditions:

- in terms of health, to be able to work;
- to be available for immediate employment;
- to be over the age of 15 years;
- to have no job;
- to look for a job.

Therefore, the number of registered unemployed comprises persons who meet the cumulative conditions set out in Law No. 76/2002 concerning the unemployment insurance system and stimulation of employment, persons registered at the Employment Agency in whose jurisdiction have their residence.

According to Statistical Yearbook of Romania [9], the quality of the unemployed is attributed, specifically:

- to the graduates of education institutions and of special schools for disabled persons older than 16 years, who in a period of 60 days of graduation, have failed to get employed on the basis of their professional training;
- to the people that prior to military service were not employed and for 30 days after their fireplace could not have employment.

The unemployment rate is an indicator by which is measured the unemployment intensity and is determined by the ratio

between the number of unemployed and the reference population (usually, the active population).

The economic practice, according to the objectives pursued, the information available and applicable law, offers the designation of several types of unemployment rates, such as:

a. The overall rate of unemployment (ORU), calculated as the percentage ratio between the number of unemployed persons (U) and active civil population (AP_c), as follows:

$$ORU = \frac{U}{AP_c} * 100,$$

where $AP_c = EP_c + U$, and EP_c – employed civil population.

b. Partial Unempl

oyment Rate (UR_i) by gender, age, socio-professional categories, counties, defined as the percentage ratio between the number of unemployed persons (U_i) and active civil population (AP_{ci}), according to the following relationship:

$$UR_i = \frac{U_i}{AP_{ci}} * 100$$

c. Full rate of unemployment (RU) - includes the partial unemployment and is calculated as percentage ratio between available working time (WT_n) of the unoccupied population and in a state of partial unemployment (visible underemployment) and total available working time (WT_t).

$$RU = \frac{WT_n}{WT_t} * 100$$

In world practice, to collect information on unemployment, they are used three data sources (like data collection methods on the active population): population census, employment survey carried out in households and collect information from administrative sources.

The current statistics in Romania, since 1992, there were monthly realized series of indicators:

- number of unemployed (the number of people entered in the labor offices);
- unemployment rate;
- structure of those seeking employment by gender, age groups, by duration of unemployment, socio-professional categories and counties.

Regarding the evolution of the indicator "unemployment" in Romania over the past 20 years, the situation is as follows:

Table 1
The unemployment rate evolution in Romania during 1991-2010

		Annual Average
Unemployment Rate (total) %	1991	1.8
	1992	5.4
	1993	9.2
	1994	11.0
	1995	10.0
	1996	7.8
	1997	7.5
	1998	9.3
	1999	11.4
	2000	11.2
	2001	9.0
	2002	10.2
	2003	7.6
	2004	6.8
2005	5.8	
2006	5.4	
2007	4.3	
2008	4.0	
2009	6.3	
2010	7.91	

Source: National Employment Agency,
<http://www.anofm.ro/>

The table 1 indicates that the decline and imbalances caused by the transition to a market economy led to an explosion of unemployment in the early years of transition, culminating in 1994 when the annual average of unemployment rate was 11%. This indicator has the highest value in 1999 and 2000, in 2010 recording 7.91%, highest since 2002 when the unemployment rate reached 10.2%.

The registered unemployment rate in Romania in late January 2011, for example, at the national level was 6, 74%, with 0.13 percentage points lower than in December of 2010 and with 1.38 percentage points lower than in January of 2010.

The total number of unemployed registered in the records of county agencies for employment was 614,976 persons, 11,984 persons less than in the end of the previous month.

Regarding the unemployment rate by gender, in January 2011, compared to the previous month, the male unemployment rate fell from the value of 7.47% in December, to the value of 7.41% and the female unemployment rate decreased from 6.20% to 5.99%.

Decreases in the unemployment rate recorded in 28 counties and in Bucharest, the most important being the reduction of unemployment in Valcea (by 0.80 pp), Caras Severin (by 0.67 pp), Arges (by 0.61 pp), Calarasi (0.55 pp) and Brasov (by 0.53 pp). In Bucharest, the unemployment rate decreased by 0.1 pp.

The highest levels of unemployment have been achieved in the counties of Vaslui (12.37%), Teleorman (10.82%), Mehedinti (10.76%), Ialomita (9.92%), Alba (9.89%), Covasna (9.87%), Dolj (9.83%), Buzau (9.74%), Galati (9.66%), followed by Gorj (9.57%) and Olt (8.68%). From the total number of unemployed registered at the national level, 315,498 are compensated and 299,478 are unpaid. The number of compensated unemployed persons decreased by 14,142 and the number of unpaid unemployed increased with 2158, compared to previous month.

5. Conclusions

The unemployment is an imbalance in the labor market, an excess of supply over working demand, with different ways and levels in countries and periods of evolution, which currently does not exclude the existence of state full employment of labor.

Employment and the efficient use of labor resources are directly related to the labor market.

There are elements that can not be analyzed separately from other components, especially unemployment, since a single component in this manner can not cover all aspects, features and effects that the overall have on work factor.

Unemployment is inevitable in a market economy, being the manifestation of the endogenous processes and actions on the

economy and society. In the literature it was offered many definitions, often controversial and characterized by diversity, but one thing is certain: is a "disease" more and more frequent in the society in which we live.

It is necessary to create a complete "image" of this phenomenon, to analyze the causes that generate its huge proportions.

Intangible Assets – Important Resources or Barriers in the Development of the Organisations ?

Bălan Ioana

"Alexandru Ioan Cuza" University of Iasi

ioana_balan85@yahoo.com

Abstract

In the evolution of the economy since the 2000s the term globalization has become a topic widely debated in the economic field with its advantages and disadvantages derived from numerous studies on the changes shown by active participants in the economic life. The concepts regarding interconnected business and transactions in real time with a high degree of certainty, the quantity and quality of information transferred and received describe very well today's economic life. It can be seen, therefore a global influence of information that, under current conditions is considered increasingly significant, more often a key factor underlying the development of international competition.

This article seeks to highlight the role of intangible assets in the new knowledge economy and future trends in development organizations.

Key words: socio-economic globalization, knowledge, intangible assets, intangible investment, evaluation.

J.E.L classification: M41

1. Socio-economic assumptions

Nowdays significant changes can be observed in the structure of national economies and the result in the form of the global economy is due to the intensification and diversification of trade relation. The concepts of collaboration and cooperation are considered as very important factors underlying the phenomenon of globalization [1].

Socio-economic globalization is a well known phenomenon when discussing, but most important is to try to understand the

influences and the ways in which it intervenes in the economic life of the society.

If we were to talk about visions, the Americans point of view on the concept of globalization [2] has long passed a simple manifestation of distance business.

Specialists are speaking today about global organizations, institutions whom main goal is that of following the business practices associated with global development and new ways of extending this concept on other countries more reluctant to this change.

In this context dominated by change on all levels the capacity of organizations of becoming more competitive, is paradoxically based on one category of resource that is able to create value-added, namely knowledge [3]. This concept is considered as one which best defines the present development of organizations. Whether we speak of technical, social, economic or managerial knowledge all manifestations of information are significant in this context of globalization.

Important aspects to be mentioned here that should be taken into account in the use of knowledge are the reliability, comparability and quality of information, the role and the significance for the organization, users and management factors in the decisions they make.

Reliability of information underpinning knowledge [4] implies a pre-existing set of rules and defined as generally accepted rules or instructions. We thus have the possibility to compare, an essential element in decision making by external users.

Comparability refers to the same organizations from two different dates (in time) or at the same time, between different organizations (in space). In the same time this concept is relevant if the organization uses the same forms of presentation and the same valuation method.

The quality of information [5] is another characteristic of information, which must be answered before all the internal and external decisions of the organization are to be taken.

Another aspect is to quantify the quality of information required by the need to issue its transcription in a form that allows adding up and comparing.

Verifiability is the quality of information which allows professionals to enable content control over knowledge, techniques, procedures imposed against certain targets. It must first meet the rules and principles outlined in the registration, classification, evaluation and procedures for the development and preservation of information.

Perhaps one of the most important aspects of financial information is the objectivity required by the rules governing national character (of the organization) or external nature (national or international laws or ordinances). If we take into account all these aspects, the development process under the current crisis can meet new dimensions. The concept of innovation is worth taken into consideration (discovery or creation of new information), as part writing (by interpretation of the) economy and default accounts, a process that aims to increase the value of the organization, enhancing competition and, ultimately, the progress of society [6]. Given present conditions, the new point of view of managers in successful companies tends to grant a greater share in the lead in new ideas and innovations, thereby decreasing importance based on previous control of the markets or raw materials [7].

We are witnessing a process of "dematerialization" of tangible assets (identifiable material nature) and drawing attention to the intangible elements, innovative potential of the organization and creating value [8]. This process of "dematerialization" refers to: research and development expenditures, those related to staff development, computer products, organizing the flow of production and marketing. But the risk must be taken that these expenses can have on firm [9]. This risk can arise in future award of costs, on the impossibility of intangible assets that were invested, the irreversibility of expenditure on staff training and the need for continuous information, generating chain costs. Despite

these risks, human intelligence has now become the primary factor in the wealth of any organization, and recognizing the importance of intangible value is one of the particularly features in the new knowledge economy[10].

2. Current accounting systems

The role and position of the balance sheet and profit and loss account information is essential in all areas of business. Although one of the main features of knowledge is recognizing the importance of intangible value[11], there is now easily found insufficient presentation of the intangible assets in the balance sheet.

The balance [12], through its role to represent the financial structure of the company provides information to investors regarding taking risks in assessing the expected return on investment and offers guarantees to creditors for the amounts advanced temporarily. To sum up, the balance sheet through its asset determines the potential capacity to provide liquidity to the entity. How tendency of most investors is to find out as much information about the business of operating performance, the role of profit and loss account increased.

Given the recent crisis the interest from investors on short-term investments increased (provided by the profit and loss) to the detriment of long-term analysis of indicators as determined on the basis of the balance sheet. In this respect, to create short-term investments the role of the intangible assets is reduced, even considering them as an expense in the period. Surrender, knowingly to these long-term expenses, we believe that a threat to the future stability of the organization. In addition to matters related to world time, treating these items as intangible assets is not always easy to achieve, in terms of relativity and subjectivity on record these items. Moreover, the use of complex and exotic financial instruments[13] have increased the opacity of the financial system and financial reporting and eventually was made public accusations of distorting information transmitted interested.

3. Identification, recognition and valuation of intangible assets

One of the main features of knowledge is recognizing the importance of intangible value[14]. But one of the major shortcomings of traditional accounting is that it highlights all the intangible assets identified as belonging to an organization[15]. From our point of view the process of identification these intangible assets is essential in current circumstances when the data generating knowledge is extremely important. For current and prospective investors, the concept of fair presentation is one of great importance but, because the risk of failure or non-assessment is high we take into consideration relevant criteria for the recognition of the existence of intangible fixed assets.

International Accounting Standards [16] define intangible assets as a resource controlled by the entity as a result of past events and which are expected to generate future economic benefits. On the other hand, immobilized intangible asset is an identifiable non-monetary asset without physical substance which is different from the character of goodwill identified [17]. As to the origin of immobilization must arise from contractual or other legal rights, regardless of whether those rights are transferable or separable from the entity or from other rights and obligations. Therefore, recognition of intangible assets in complying with a series of criteria relating to: identify what a character is to be distinguished from goodwill, the organization can have control over their ability to generate future economic benefits and the possibility of a credible evaluation. Currently, the world of ideas becomes a priority in relation to the tangible world of objects and intellectual capital becomes a priority in relation to other forms of physical capital. Under this form of manifestation of knowledge, intellectual capital includes four categories of intangible assets, namely [18]:

- a. asset market: trade, market segments, reserve orders, distribution channels, contracts of assignment, licensing, creating competitive advantages of market organization;
- b. infrastructure assets: technology, work methodology, specific techniques that make the organization function

effectively. These values related to how employees communicate with each other and relationships within the organization.

c. active intellectual property: copyright, software patents, industrial designs;

d. human values: employees' professional skills, including experience, ability to enunciate and solve problems.

Those values are crucial for the organization because it is expensive to hire, train and maintain such a high value. Therefore it is important that the organization can have control over the use of these types of resources. It involves drawing benefits, especially future economic benefits arising from the involvement of such property and to restrict third party access to those benefits.

All these above mentioned features lead to a series of future economic advantages that may be associated with them. Therefore it is very important to have in mind the use of reliable assessment techniques as to reduce the risk of underestimation or over-appreciation of assets [19].

In these conditions if the item is purchased separately, the price reflects the probability that the resulting benefit to the company owned. So we can talk about an acquisition cost (accounting) in conjunction with the auxiliary (direct costs of preparing the asset) [20].

On the other hand, intangible assets can be internally generated and it s very interesting to see how their value can be determined on stages (research and development).

In the research phase costs are driven by the quest for new knowledge, formulation and selection of alternatives.

Development phase, on the other hand, involves expenses that can be capitalized if it is apparent intention to complete the task later ability to credibly sell the asset at a price fair and credible results from the assessment of the costs involved in earlier stages. Not many times all these factors with a role in facilitating the recognition of intangible assets may have values that are difficult to estimate as depreciation is difficult to calculate. Although the life of such assets is very long or even indefinite, we consider that the markers are not justified some accountants do these types of assets, reducing life to a very short period of time resulting in financial statements "embellish".

4. Conclusions

The company is clearly a complex process of transformation of the global operating variables (whether physical or intangible assets). They ought to be known in detail so that decisions taken should be the highest quality and ensure the organization continuity. If we can say about the physical assets that can be identified, cataloged and recorded, when it comes to intangible assets situation changes. Methods such of identification, evaluation and amortization are still considered difficult to apply by the accounting specialists even when there are laws and implementing rules. As the Romanian and international accounting rules do not require mandatory disclosure in the title of financial statements of these types of assets, reporting their presence is quite short.

In addition to this aspect of representation, another aspect to remember is the specialist task in determining the amortization period. Moreover the accounting and tax accounting so often creates problems.

The phenomenon of globalization, we believe that besides knowing the benefits has drawbacks especially for subsidiaries of multinational companies. Here, the prospect of intangible elements must be kept as required by the parent company and the nature of the country of residence tax. Not only that this is made difficult with a set of additional resources (financial, human, etc.) but can sometimes be incorrect or irrelevant.

Considering all these aspects mentioned above intangible assets becomes an issue of great interest both for specialists, managers and investors, and recognition, use or development may be key to resolving many problems that organizations face today.

The architecture of the proposed information application as a case study requires the presence of three fundamental components:

a. **The database** – represents the fundamental element of the analysis. These elements represent a relational structure and client-server architecture, representing in many cases the result of the integration of an ERP system in the decisions of a wood exploitation and processing company. The systems from this category are oriented upon transactions, the analysis possibilities being limited as a consequence of the functional architecture of the system. The relational systems cannot accomplish efficiently the analysis process, the adequate transformation of those being necessary in order to respond to the requirements. Also, the operational systems the available data cannot be accessed from many internal and external informational sources of the public institution;

b. **The transformation of the data and the creation of the data storage** – Taking into account the limits of the operational systems, in order to make the optimum analysis the data transformation process must be made. For this we can use Data Transformation Services (DTS) from SQL Server 2010, with the help of which it can be possible to connect to any data source and extract the information, and in the end we can generate the analysis cube.

The data extracted and transformed are saved in a data storage that can contain multidimensional and relational data structures from the data storage. We can consider the data storage as a gathering of all information from initial data sources. On the basis of the information from the data storage we can generate cubes for the multidimensional analysis as well as specific data subsets dedicated to some specific subjects (Data Marts);

c. **The users** of the informatics solution will connect using the web browser and will extract the data subsets which will be analysed at the local level. They can also create and particularize interrogations which can correspond to the requirements of the beneficiaries of the wood exploitation and processing companies.

In order to make such a multidimensional analysis the following operations will be made:

➤ The application of the mathematical functions and consolidation functions for the elements situated at the basis of the elements hierarchy;

➤ The classification of the data using the group operator for each dimension of the database;

➤ The making of the cross tabs (cross-tab), which will include the representation of the data in bi-dimensional structure;

➤ The joining of the bi-dimensional representations and the obtaining of the results in a multidimensional form.

The Business Intelligence component developed within the informatics system for assisting the decisions requires the use of the following essential **elements**:

1. **The connection to the data storage** – in order to connect to the data source the ASP.NET technology and the possibilities offered by the .NET framework environment will be used.

The data will be transferred towards the customer using the XML language and the Web services, on the basis of the following source code:

```
<WebMethod()> Public Function
InitializePivotTableXML(ByVal
strDataMember As String) As String
Dim m_XML As String
Dim strOLAPConn As String = _
ConfigurationSettings.AppSettings("OLAP
ConnectionString")
Try Public Administration Information
System
Dim objPT As PivotTableClass = New
PivotTableClass
objPT.ConnectionString = strOLAPConn
objPT.DataMember = strDataMember
m_XML = objPT.XMLData
objPT = Nothing
Catch err As Exception
m_XML = "<err>" & err.Source & " - "
& err.Message & _
"</err>"
Finally
End Try Public Administration
Information System
Return (m_XML)
End Function
```

2. The interaction between the client and the server – in order to make this interaction between the client component and the server component a series of ASP.NET scripts were made using the Visual Basic.NET language.

3. The securing of the transfers – taking into account the importance of ensuring confidentiality to the OLAP reports it is necessary that the technologies used must allow a safe access to information. Taking into account these considerations the SSL technology was chosen (Secure Sockets Layer), and a security certificate is used for the Analysis Services component.

Within the companies, the informational systems in general and the ones based upon computer technology especially impose the acceptance of the idea that producing the information is an independent field. Due to the extension and the generalisation of the information production fields, the managers of the companies have new attributions connected to the increase of the role of information in the decisional act. In these conditions, new competences appear connected with:

- the control and the management of the web based information and communication technologies;
- the designing or the redesigning of the information systems connected to the increase and the diversification of the social-economical services;
- the acquiring of abilities in the use of the computers to produce information for the elaboration and the monitoring of the decisions within the companies for accomplishing better organisational performance.

The modernisation of the information systems becomes an attribute for the performance of the organisational management. According to the idea that an informational system is a set of organised procedures, we can say that the produced information is destined to sustain the objectives of the companies. Currently the perfecting and the implementing process of an informational system are strictly connected to the integration of the computer technology in the management process. According to the objectives and the size of its services and attributions, a company can find itself in a situation to process an

impressive amount of data, and an Internet technology information system definitely brings a bonus in the processing speed. As an institution has relations with other companies, a diversification in the destination of the produced information appears. Thus, some of these information are destined to be used by the employees of the company, according to the requirements of the management, and some of these must be putted at the disposal of the consumers (information referring to products, services, etc.) or to the state (information referring to the financial data). Without an informatics informational system, this thing is not possible.

Although the processing of the information is not the most important objective of most of the companies, it represents a vital component of their operational framework. Thus, the managers are the coordinators of the design and the beneficiaries of an informational system in the same time. The different types of decisions require different types of information, and their major source is found in all the operations made within the company. The presence of different information reception methods complicates the decision process and increases the urgency to perfect the informational system using informatics.

Due to the fact that the impact of information technology is different from the impact of other type of technology, any company must carefully manage information due to the primal effects, but especially due to the potential side effects that these can generate.

There are three information technology integration levels within a company:

The first level is made up from independent informational systems which help the public institution to implement the strategy by increasing the efficiency of its activities. These systems are not directly connected with the strategy formulation process or integration into a certain strategic plan.

The second level is characteristic for the systems that support the policy of the company and are designed to boost the strategic planning process of the company. In this case the systems help to formulate the strategic plan but are not an integral part of

this plan. It results the fact that the systems for the integration of the information technology are not part of a finished product or a service produced by the public institution.

The third integration level becomes part of the strategy of the company towards a performing organisational management. At this level, the information technology and its integration within the decisional level is in a close connection with the strategic thinking of the management by its contribution to define the options and possibilities area. In the same time it offers the means by which the strategy, once it is chosen, will be implemented. In the business environment, at a given moment, a company that benefits from the advantage of such an integration level of the information technology in the decisional process can find itself competing with institutions that develop similar information systems.

Within a company, one of the fundamental roles of management is the control and the monitoring of the manner in which the decisions are made. A manager permanently needs information upon the deviations from the proposed objectives. The information systems that assist the decisions have an important contribution. A decision assistance system is a computerised system that ensures to the user models for solving some problems that a manager must solve.

It must be highlighted the fact that these information systems are created in order to offer a support in taking decisions within the company and not to effectively take the decision. In each information system there are designed different alternatives destined to ensure the solving of different problems. For each alternative there is a certain risk rate in the implementation phase which is impossible to evaluate in terms of costs. Nevertheless the decision assistance systems represent efficient tools for the management of the organisational performance.

We can notice an outlining of some directions connected with the monitoring of the information systems based upon decision

assistance systems.

A first direction is connected to the consolidation of the control systems, which are mainly situated in the cost control area, and on the other hand in the area of perfecting and creating new informational systems for a performing management.

The computerised informational systems offer the possibility for the companies to make a large number of operations ensuring in the same time a control and a permanent reduction of the errors.

A second direction is given by the involvement of the informational systems even outside the companies. The lack of experts in this field will guide the institution to purchase applicative software packages. As a consequence, the companies will be forced to modify their procedures in order to the benefit from the existent technology. They will purchase "turnkey" information systems for a certain level of generality and will be forced to adapt their procedures according to these requirements.

The third direction refers to the contribution of the informational systems to the increase of the economic efficiency. It derives from the fact that the information has an increase extent in the modern organisational structure. The use of the information processing technology is currently a primary component of the strategy of a company.

The General Architecture of the Integrated Information System of Assisting the Group Decisions for the Organizational Performance Management

Bălan Ioana
jurist
ioan@balan.ro

Abstract

The decision assistance systems are based upon the evolutionary and predictive models, which have the largest successful rate. In this way, mainly a hybrid model of the informational system is created, and as the user interacts with the system, the information area based upon competitive intelligence increases and the information system evolves in time using upgrade operations.

Key words: system,business,companies

J.E.L. Classification: H1

1. The characteristic elements of an information system of assisting the group decisions

Taking into account the participation of several persons at the process of decision making, the information solutions of assisting group decisions (ISAGD) present a series of features regarding the ways in which the decisional process is accomplished. In order to explain, we are going to present some distinctive elements of these categories of solutions:

► The decisions making implies debates or discussions and negotiations between the participants at this process. Each participant at the decisional process can propose his/ her own strategy in order to solve the problem, and as a result of the discussions there are going to be made compromises and taken a common (joint) decision.

► The interpretations regarding the data and information on the basis of which there are taken different decisions, this thing

determining important differences in the resolutions of each participant.

► Taking into account the different technical knowledge of the participants at the discussions, the ISAGD solution must have a simple user interface and to be easy to use.

► The existence of a Web interface of the ISAGD solution can be a requirement in the situations in which the group decisions imply the existence of some participants from different geographical locations.

Taking into account the time-space coordinates, within a group ISAGD for the public administration we can identify the following features:

► The distance that separates the decision makers – in relation to this element the decisional process can be achieved or accomplished in the following ways:

I. The decisions are taken in a meeting (sessions) room where the participants are gathered at the decisional process and debates take place.

II. The decisional process is achieved or accomplished through the internal network or using the Internet. In this case there are used various IT solutions in order to ensure the communication between participants (electronic mail, chat).

III. Using complex solutions in order to ensure the communication between participants, consisting in video conferencing systems and other solutions.

► The temporal coordinate in the decisional process in a group ISAGD constitutes the decisive element regarding the architecture of the systems of decisional support. In the situations in which the users do not participate simultaneously at the decisional process there are going to be used electronic means in order to ensure the asynchronous communication between them.

► The way of achieving control upon the decisional group – In most situations, the

decisions in the public administration are taken democratically, through negotiations between participants. In the situations in which there are controversies between the decision makers, a mediator can intervene in order to achieve compromises and common (joint) decision making.

➤ The type of communication between the participants – in terms of this feature, we can identify two ways of communication: the point to point communication between the participants and the broadcasting type communication.

The groupware concept is defined as the methods, procedures, programs and computer platforms assembly that allow the persons associated to a project to work together with a maximum of efficacy. A group is constituted through the creation of connections between the workstations, offering the assisting of the communication activities, collaboration and coordination between the members of the group.

In order for a information/ computer system to be considered groupware, it must integrate or include all the work requirements of the members of a group or organization, namely: communication, by using the electronic messaging, collaboration, by sharing the informational resources among the members of the group, coordination, by adding communication and collaboration in the structure of the specific activities.

From this point of view a groupware system can be defined as an integrated set of instruments that allow the decision makers to work together, through communication in certain time intervals and in different places.

The fundamental or main objectives of the group decision- making systems are described below:

➤ The sharing of information, reflected in the common sharing of data, texts, knowledge that are accessible both to the individual users who perform or accomplish their current tasks, and to the decision-making group members;

➤ The implementation of projects by using specialized software. It involves the use of certain specialized instruments for the development of the solutions of the ISAGD group type. The development methodology includes the proposed objectives, goals and projects for the accomplishment of the

objectives and actions to be taken in order to solve the projects;

➤ Achieving in collaboration the technical documentation, the reports and other documents, including multimedia documents;

➤ Electronic conferencing using communication technologies and computers as well as computing technology;

➤ The management of the systems messages that constitute as an extension of the facilities of email and represent communication ports (gates) both to the exterior and to the interior of an institution within the public administration;

➤ Assistance in the establishment of working groups, through some specialized programmes that coordinate the actions to be taken and establish the persons who can be grouped effectively in a team, with a leader.

The information solutions of assisting decisions (ISAGD) model proposed by us is based on a components assembly, technologies, solutions of server type, as well as design and development instruments of the information systems. An aspect which we consider relevant and we wish to highlight regarding the accomplished system is the orientation towards Web and Internet of all the applications that enter in its structure. In this way, all the programmes that form the ISAGD group solution are based on web technologies, this thing ensuring a simple and uniform access to the informational resources. The orientation towards Web of the information system was chosen in order to respond to the following two fundamental needs of an institution within the public administration:

➤ Decentralized access to information from the Intranet network of the public institution or through the Internet environment, facilitating in particular the following three types of transactions:

1. *Business-to-Business* (B-2-B) that covers all the transactions between companies

2. *Business -to-Employee* (B-2-E) refers to the transactions intended for the employed staff and that are carried out through its own Intranet system.

3. *Consumer-to- Business* (C-2-B) is a trade category intended for the field of social benefits payments or of the

compensations established after the calculations of global income.

➤ Mobility and uniform access to the limited resources, considering that it must meet the following functional requirements: to allow the cooperation of OS at the customer level, network and server, to allow the work in the mobile regime and remote conditions and to ensure the interactivity between different entities.

The information system of assisting the group decisions proposed model for the efficiency of the managerial activities

presents two fundamental levels that ensure the overall functioning of the information system:

a) The infrastructure level – includes the components of the server type that are going to constitute the basis/ foundation of the developed application level (file server, database server and Web server);

b) The applicative level – includes the proper applicative components, that exploit or operate the data sources and accomplish their analysis processes (figure no. 1).

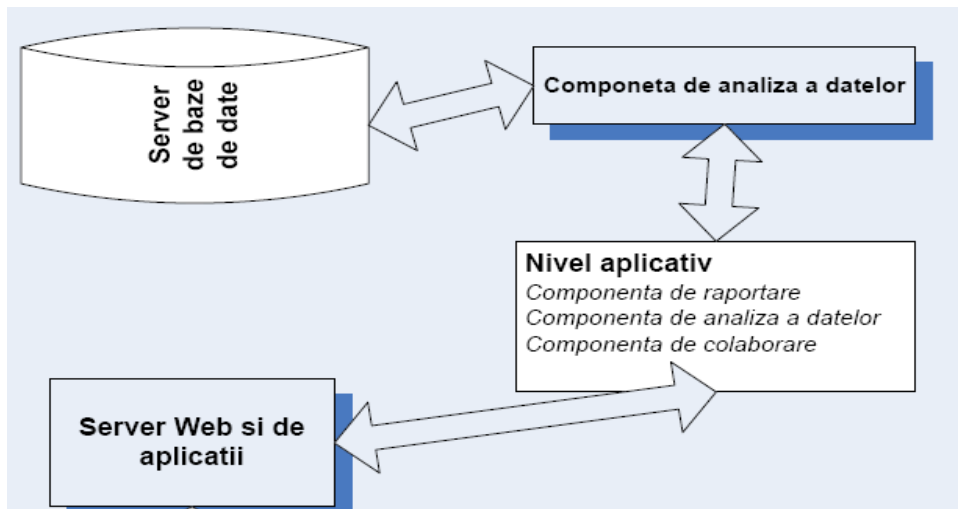

Figure no. 1 – The fundamental components of the integrated information system of assisting the group decisions for the organizational performance management

2. The infrastructure level

The infrastructure level ensures and provides the basic needs of the information system of assisting the group decisions for the organizational performance management and the interaction with the users. In the case of this level we can identify the following available functions, but integrated within this component:

a) The function of file server and of hosting the other components of the information/ computer system;

b) The data storage functions and of integration of analysis functions specific to a decision assistance system (OLAP or data mining);

c) The Web server system that ensures the interaction with the users of the information/ computer system;

d) The software framework and the components that ensure the functionality at the applicative level of the developed solutions;

e) The functions and components that ensure the overall security of the information system.

3. The applicative level of the information system model of assisting the group decisions specific to the companies of wood exploitation and processing industry

The applicative level is composed of the set of developed applications and of the implemented components, both components contributing to the ensuring of the functionalities of the information system of assisting the decisions. I considered it

appropriate to present the scheme of the proposed information system (figure no. 2).

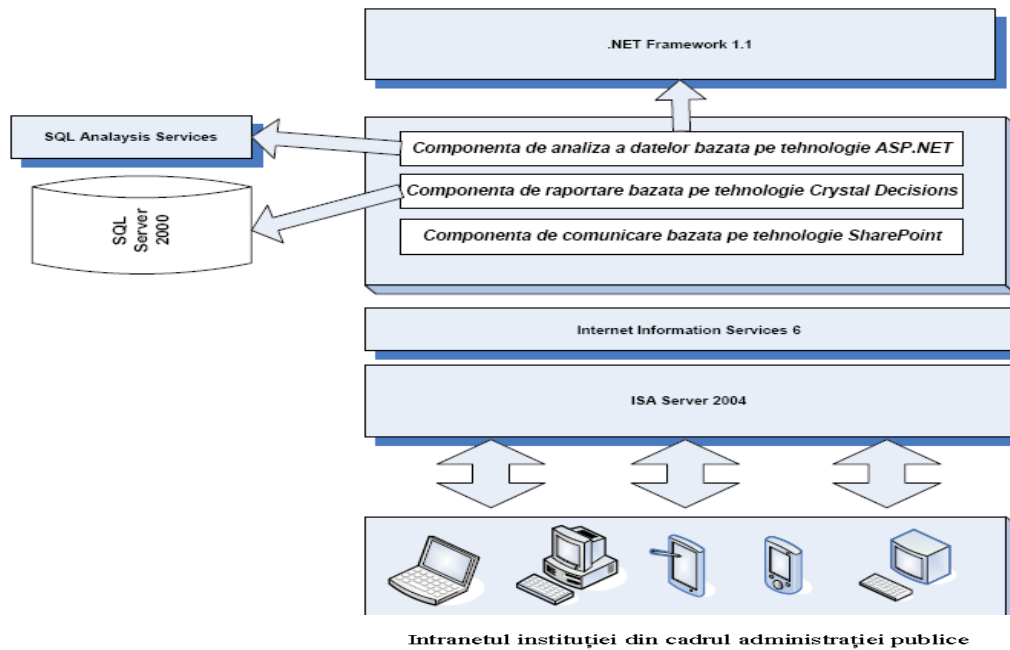

Figure no. 2 – The scheme of the information system of assisting the group decisions

The main functions of the reporting component can also be seen or observed from the diagram of the use cases (figure no. 3), in which it can be distinguished two generic actors/ stakeholders (administrator

and user), these ones integrating the various functions of the designed information system (the management and establishment of the access rights, the construction of the personalized reports).

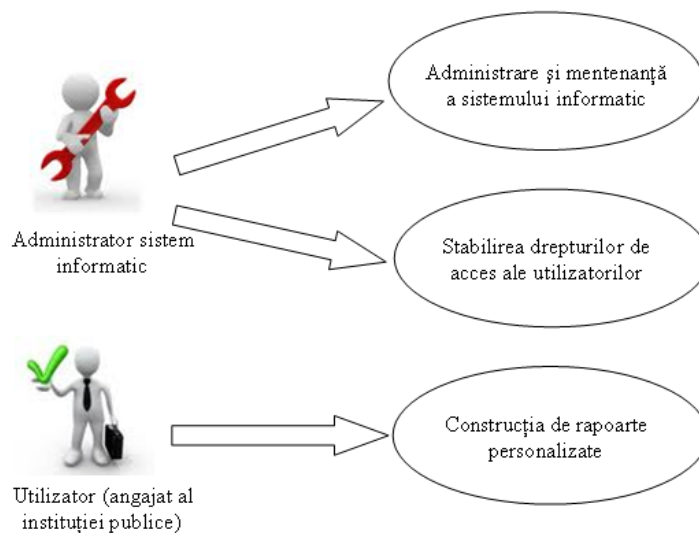

Figure no. 3 – The diagram of the use cases dedicated to the reporting component of the proposed information system

Crystal Reports is one of the most powerful generators of reports that are available at the moment, which I successfully integrated in the model of information system of assisting the decisions. Crystal Reports is a professional instrument that allows the visual construction of the reports, as well as the connection to a wide variety of data sources. Besides this, through the Crystal Enterprise instruments, we have the possibility of publication and management of the reports submitted through a Web server.

Also, I included in the proposed information system the Crystal Decisions component, which also includes a professional solution dedicated to the achievement of the economic analyses on the basis of the OLAP technology. Crystal Analysis is the instrument dedicated for this purpose, having as main advantage the simplification of the achievement process of the data analysis reports. The program allows the connection to various data stores, disposing of a well- organized interface.

The central element of the portal accomplished through the Crystal Enterprise solution is the ePortfolio instrument. Through

this instrument, the managers have the possibility to access and preview the accessible reports through the Web portal. Supplementary, the reports can be organized on more categories through the folders, also being implemented a search engine after the name of the report or its description. ePortfolio is a web interface that can be personalized, through which the users can visualize the programme and can publish reports.

Crystal Management Console (CMC) allows the management of the whole information system of assisting the decisions. Through the CMC there are established the authentication and security settings, there are added the users and the groups of users. This instrument allows the complete administration or management of the servers and groups of servers on which the Crystal Enterprise solution is available and is available in the form of a web application, thus facilitating the remote (at a distance) achievement of the efficient/ performance management operations.

Abstract

In this paper we realized an extensive review of the decision-making process as it was developed in the specialty literature. Decision-making is one of the most important managerial issue to which a great attention was devoted by the specialists. However the efforts to synthesize all the vast research were scarce. For this purpose we present in our paper the classical theory and the new models. In our opinion a decision-maker does not use only one of the modalities of decision-making. Another hypothesis is that the decision-making should be regarded less as an exact science with quantifiable parameters. Probably is too much to consider the decision-making an art. It is obvious that decision-making has its shadow areas in which the imagination, the intuition, the creativity, the emotions of the decision-maker can bring some light.

Key words: decision-making theory, decision-making models.

J.E.L. classification: M10, M16

The managers' decisions have a profound impact on the success of the enterprises. The studies regarding the decision-making process are numerous, being elaborated by economists, sociologists and psychologists. Within the representative studies there are two major categories of models that explain the decision behavior: normative models and descriptive models. The normative theory explains the way in which a decision should be made, while the descriptive theories reflects the way the decision-making process takes place in reality [1].

1. Classical theories of decision-making

1.1. The normative theory

The main assumption of the normative models is that of the rationality of the decision-maker. Generally a human-being is rationale if he is noncontradictory [2]. A second assumption of the normative models is that the decision-maker knows all the alternatives and selects the optimal course of action.

Apart from these two assumptions, other authors add other hypotheses: the number of decision-makers and the unanimity of objectives. The number of decision-makers represents an important issue in the normative models. Some authors consider that the decision-maker represents the core of the normative models, also known as the models with unique actor. The fact that there is a unique actor means that the decision is taken by a single decision-maker or a group of decision-makers that act together, having a common objective. There are no conflicts on the objectives or the decision-making process [3].

The hypotheses of the normative models are, as mentioned above, hard to be identified in decision-making context in economic life. The rationality does not seem to be anymore characteristics of the economic life. G. S. Becker notes [4]: "While for a long time the traditional economic theory assumed that human behaviour is rational, at certain moment there was a major contradiction regarding the meaning of the concept rational. For many people the word suggested a older psychology, fast calculus abilities, hedonist motivation and a possible unrealistic behavior. While the economic theory becomes clear and more precisely formulated, the controversies diminished, and

now everybody agrees that a rational behavior implies only the permanent maximization of certain well defined functions such as the utility function or the profit function."

Still, in adjusted forms, the normative models prove to be useful in decision-making regarding the choice of investment. The most known normative models calculate the expected value or the expected utility.

1.2. The descriptive theory

The descriptive models of managerial decision-making, compared with the normative models, suggest that the difficulty to obtain the information and the limits of processing complicate the decision-making process. In the category of these models, the researchers identified many models such as: the satisfaction model, the incremental model, the garbage can model, the political model.

In the years 50', Herbert Simon began to study the real behavior of management decision-makers. Instead of the "economic man" Herbert Simon proposed the model of "administrative man" that acts based on "limited rationality". While the "economic man" maximizes by choosing the best alternative, the "administrative man" formulates an aspiration regarding the alternative that need to be identified and when this aspiration is met, then the search is over, the respective alternative is selected as decision [5]. This is the essence of the satisfaction model based on limited rationality.

George P. Huber considers that the managers usually become accustomed with a simplistic approach, even when the costs of investigating a better alternative are justified by a potential winning [6]. It is important to be noticed that the satisfaction model leads to a rush decision and the solution found is, in many cases, a trap hard to avoid.

There are further developments of the limited rationality, such as the interactive rationality. The organizations help the individual "to get closer to reasonable distance of limited rationality" (H. Simon), respectively the environment can help the individual to focus on elements that must be analyzed and checked with priority, and these elements can ensure coherence to its choices.

Another concept resulted from the limited rationality is the embedded rationality. The concept was introduced by K. Polanyi but popularized in the literature by M. Granovetter. The activity of organizations has a powerful determinant in the relationships that are established with other organizations. Their activity is socially embedded, respectively inserted in a network of relationships. The organizations exert their own influences on the other actors from the economic and social environment. Besides social embeddings other authors describe other forms of embeddings such as the political embeddings. The rationality can be regarded as a resultant of inseparable economic, political, sociological and psychological forces.

After H. Simon, James G. March is another remarkable author that focused on the decision-making process. He considers that decision-making is a process that can be perceived "in the same non-rational way as the painting of Picasso or the poetry of T.S. Elliot". The complexity and the ambiguity of contexts, present in the decision making are many times underestimated.

In these conditions, J. G. March, together with D. K. Cohen and J. P. Olsen have proposed the model of garbage can regarding the organizational choice. In this model the managers have a random behaviour, quite non-scientific, in non-programmed decision-making situations.

The strategy of the garbage can is used when the manager does not have a preferred objective. This kind of approach can be observed when it lacks a solid strategic management. The outcomes when using this decision-making model are mixed: sometimes favorable but also, in many cases, the consequences are not favorable.

A third model, developed in the literature is the incremental model according to which the managers make efforts to reduce the decision-making situation to a tolerable level. The decisions are made to reach a palliative objective, solving a short-term problem instead of tackling the long-term issue. The same with the satisfaction model, the incremental model does not motivate the managers to process a large quantity of information to elaborate the decision.

The incremental vision of the decision-making developed from the research of Charles Lindblom. He describes two approaches that can be used in the decision-making process: a comprehensive rationale method and a method of limited successive comparisons.

The comprehensive rationale method, also known as root approach, is similar with the normative models of decision-making. Following the root approach, the decision-maker can clearly spot the objectives that are relevant for decision. Also, the decision-maker identifies the compensations that can be made among objectives, respectively the level in which the gains compensate the losses [7]. These compensations are established before a particular problem is to be studied. According to the root approach the decision-maker is considered to have an extensive knowledge about a set of alternative solutions and detailed knowledge regarding the consequences of applying the solutions. Based on this knowledge, a large number of decisional alternatives are compared and the alternative chosen is the one that satisfy in the highest degree the objective.

The root approach is more like an ideal, because it cannot be transposed to the realities of decision-making process. The mental capacity of the decision-maker is not large enough to be confronted with an avalanche of information and alternatives involved in the root approach. In practice, the decision-maker is not confronted with intense mental efforts, because the usual information is incomplete and inadequate, at least from the point of view of high cost involved in information gathering and processing.

In the case of limited successive comparisons method or the branch approach, the decision-maker identifies many alternatives to solve problems. The identified alternatives are not very different from the policy and the actual experience of the enterprise. From these alternatives one is chosen, that is relatively easy to be implemented. Then, if there is the need for improvements, the process starts in the same manner.

The limited successive comparisons methods delivers a pragmatic feature to the process of decision-making and takes into consideration the limited ability of the decision-maker to identify and evaluate a

large number of alternatives, ones very different from the actual experience. The branch approach is focused on those solutions that solve the relevant aspects of the problem. While the conventional approach sustains that the means need to be adequate to the goals, the limited successive comparisons method implies the reverse that is the goals should fit the existed means. The existed information should be revised and reinterpreted, the proposals are rethought, the values are permanently modified.

The incremental method has a potential applicability in politics, because it is easy to develop an agreement, a contract, in case the solutions involves minor changes and not profound changes. This model is based on the fight for power among the stakeholders of an enterprise. Within the organizational environment, the stakeholders develop strategies to reach solutions in accordance with their personal objectives. The management of the organization, responsible for the decision-making process, has the tendency to choose solutions not based on existing general objectives, but its decisions should conflict as little as possible with the strategies of the stakeholders. The available solutions are limited. In order to avoid seeing his decisions banned by ad-hoc coalitions, the manager tries to figure his position on the map of interests, the so called "the corridors of indifference": issues where no clear opinion is expressed or susceptible to be expressed within the organization. In these indifference areas, the manager emits proposals that can be accepted by all the actors involved, because they do not rises any major inconvenience.

Another method of decision-making, widely known, was developed by A. Etzioni. This method was perceived as the third way, opposed to the rational method and to incrementalism. In 1989, A. Etzioni believed that in the years to come decision-making it will be more an art and less a science [8]. The model he proposed, the model of mixed scanning involves different levels of decision-making, respectively a superior level comprising the fundamental decisions (the mission and strategy of the organization and the policies to implement the strategies) and a inferior level comprising incremental decision-making that support the realization of decisions from the superior level. The

author considers that this model is an older approach better explained. His model has precedents in medicine. Each doctor has as objective to heal its patient. For this purpose he establish a diagnostic, effectuates the investigations, then he prescribes a treatment. In some cases the treatment is not good enough forcing the doctor to change the treatment. In a similar way acts the decision-maker in an organization when he uses the adaptive model. He identifies the problems, analyzes the difficulties, start an action and if he's not successful he passes to another course of action, not losing from its sight the mission and strategy of the firm.

In the recent years a new model for decision-making developed: the naturalist model. The model originated from the papers of G. Klein, J. Orășanu, R. Calderwood and C. Zsambok, published in 1989.

The model specifies that each decision is specific to a certain context and the analysis and understanding of a decision cannot be separated from its specific context. The conditions in which this model can be applied are: changing environment, missing or incomplete information, adjustable objectives, the inexistence of some procedures, of clear tasks, the constraint of time, the necessity of actions in real time as a response to environmental changes, experience and solid expertise of the decision-maker.

2. New models of decision-making

Apart from these classical approaches, in the literature there are new developments of decision-making models. In a well known paper H. Mintzberg and F. Westley describe three models of decision-making: the model based on reflection ("thinking first model"), the model based on vision ("seeing first model") and the model based on action ("doing first model") [9].

The model based on reflection is a rational model to which its authors find a series of limits, firstly because it is only a theoretical model, without a larger practical application. Considering this aspect, the two authors propose two new models.

The model based on vision suggests that the decision or the actions can be oriented more by imagination, anticipation rather than

reflection. The vision requires the courage to see what others do not see.

The third model proposed by H. Mintzberg and F. Westley is a model based on action. Many decision-makers consider that is much more important to act, after which to analyze this experience and to learn from mistakes. We can learn both from success or failures. When the preoccupation for reflection, in order to act according to a well established plan, becomes a obsession, learning by doing can be discouraged.

In the next section we will present two new models of decision-making at organizational level, the so called irrational. In our opinion a proper designation of these models it will be non-rational. We will make a few clarifications to sustain this idea.

The studies in the area of neurobiology showed that there is a difference between the contributions of the two brain hemisphere to the mental life of a person. The left hemisphere is responsible for language, logic calculus, rationality, capacity to analyze and to think abstract. The right hemisphere is the universe of thinking without the language, of non-verbal understanding, of spatial perception. Its task is to synthesize and to express the experience of a person in a image. The imagination and intuition are its dominant functions. The approach is intuitive (opposed to the rational one) – it works through ideas association, interactive approach, there is a synthesis of relations among objects in order to rebuild the information in a unitary approach [10].

Two new concepts need to be clarified to fully understand the last two models: respectively the imagination and the intuition. The imagination is the mental faculty allowing the elaboration of new associations by composing and decomposing the ideas, by combination and recombination, in the end creating objects, situations that never existed in the nature. The intuition refers to the tendency to reach a conclusion or to fulfill an action without detailed explications regarding each step of the process.

The intuitive model of decision-making is not approached in a global manner, thou exists many dispersed approaches. Many authors admit that intuition can play a powerful role in the decision-making process

without describing the exact nature of these influences.

M. Le Saget, in his known paper "The intuitive manager" considers that in an ever complex environment there is a tendency toward simplicity, toward what is easy accessible, toward fast understanding. There is the need to equilibrate the logic and analytic thinking by another form of reasoning that will allow to immediately seizing a situation: a intuitive reasoning".

F. Vaughan considers that the intuition is a psychological function that each individual poses at an acceptable level. C. Jung believed that intuition should not be regarded in antithesis with rationality, only being different. The intuition is defined by some authors as being a more sophisticate type of rationality based on "illumination", belonging to some specialists with experience in a certain area.

Karl Weick appreciate that the intuition is a "condensed experience" synthesizing quite powerful the way in which the accumulation of information seem to be the manifestation of the unconscious. There is a difference between the intuition of the leader dominated by emotions and the intuition of experts. The intuition of experts is the result of learning, of experience while the first is the result of basic emotions that also diminish the attention. It will be a grave confusion to overlap the non-rational decision that results from the intuition of expert with the irrational decision that can be generated by stress and negative flows of emotions [11].

In many cases the intuition is overestimated, being used to justify the idea that there is no longer the need for self-discipline and rigor, in the logic of "if this is what you feel then this is good for you". Pushed to the extreme this tendency destroys a persons and he can lose contact with reality [12]. The intuition should be seen as a complement of the rational thinking and not as a replacement of this.

The intuition can be used with good results for non-programmed decisions, especially in an unstable environment (in risky and uncertain conditions). This method can also be used when the decision-maker did not met with a similar decisional context and he doesn't know other similar experiences of other decision-makers; also this method works when there are many

decisional alternatives viable that are difficult to evaluate with other tools.

Also the imagination can affect the decision-making process. Related to the decision-making process, the imagination can be used to reach some objectives into a negotiation process, in solving interpersonal conflicts, in building consensus at various meetings, establishing objectives in various contexts, the evaluation of the general conditions of organization, solving abstract problems. In the decision-making process imagination can help to identify the problem (taking into account the symptoms that appear) and in selecting the alternative that must be implemented.

A. Tannenbaum considers that creativity is another useful process for the decision-making situations also ensuring a better communication in organization, allowing a better investigation of the problem and the development of new ideas, solutions and alternatives [13]. A development of this issue belongs to Edward de Bono in his work "Lateral thinking". In his opinion: "The purpose of reasoning is to get information and to use them in the most efficient possible way. The vertical reasoning deals with the creation of conceptual models. The lateral thinking deals with the restructuring of these models (intuition) and determination of new models (creativity). The lateral thinking and vertical thinking go together in a complementary fashion" [14].

At E. de Bono we have identified the synthesis in which the creativity can help the decision-making. He believes that there are three types of problems: the first type of problem requires more information and better techniques to handle the information in order to find solutions; the second type of problems does not require new information but only a redistribution of the existing information: an intuitive restructuring; the third type of problems, that is the existing arrangement is optimal, and this stop us to search a better one. The second and the third type of problems require the use of lateral thinking and to discover a solution.

A somehow similar reasoning can be found in the paper of H. B. Gelatt and C. Gelatt, "Creative Decision Making". The two authors introduce the notion of "positive uncertainty" [15]. They consider that the uncertainty present in quasi-all decision-

making contexts should no longer be a something the decision-maker must worry about, but one must embark on positive attitude. Based on this attitude there are several options for the decision-maker and he can manifest a proactive creativity. The reasoning of the two authors is quite simple. If someone is absolutely positive about what should follow, then he thinks only about this possibility, and if there are no perturbations this will actually happen. When the decision-maker is uncertain about what will follow then he is free, capable of studying many alternatives. In this case he needs the model of creative decision-making. The authors require flexibility saying "If you know exactly where you want to go you will never get somewhere else".

In this context we have to mention that the emotions of the decision-maker have a strong impact in the configuration of the decision-making process. These can affect the optimal decision-making by distracting attention or by distorting the perception over the options".

Certainly the creativity, the intuition, the imagination, the management of emotions are in the new conditions the necessary ingredients of a efficient decision-making process, but the dispute over the role of rationality seem to be pushed too far. Even if we have to use a cliché, we believe that the truth is somewhere in the middle.

3. Conclusions

In our opinion a decision-maker does not use only one of the modalities of decision-making. In his decision-making activity, many times in unconscious manner, there are different modalities to adopt a decision based on the specific of the decisional context. Another hypothesis is that the decision-making should be regarded less as an exact science with quantifiable parameters. Probably is too much to consider the decision-making an art. It is obvious that decision-making has its shadow areas in which the imagination, the intuition, the creativity, the emotions of the decision-maker can bring some light. Further research is needed to investigate the decision-making process by taking into account all the above mentioned elements.

The Capacity of Absorbing the Structural Funds Romania vs. Bulgaria

Berica Corina

„Alexandru Ioan Cuza” University of Iași

corina.berica@yahoo.com

Abstract

The capacity of absorbing Structural Funds continues to be a „taboo” subject for everybody. The image of irredeemable financing generates a continuous feeling of satisfaction and the desire to become rich. I use the word „image” because the Structural Funds have managed to cover in a fairytale vale a reality of disappointment and distrust.

I have decided to speak in this essay about the capacity of two neighbour countries, similar from the social and economical point of view. Romania and Bulgaria, two countries with great perspective, with the possibility to reduce the economical and financial disparities compared to the other EU states. My dilemma is the following: if they started from approximately the same economical stage, with the same wellbeing aspirations, how did Bulgaria manage to beat Romania regarding the absorption of the Structural Funds? Is this simply an accident or is it that we, Romanians, demonstrate each day that we don't deserve anything?

Key words: Structural Funds, absorption rate, difficulties, solutions

J.E.L. classification: F35, O11, O52

1. Preamble

The European Union suggests the reduction of the economical and social disparities among the EU Members by the use of the Structural Funds. The Structural Funds are tools used for implementing the cohesion policy adopted by EU. It is important to analyse the manner in which the member states react facing such benefits. Significant differences are normal from one country to another, because the absorption

degree of the Structural Funds is influenced by a series of factors, among which we could indicate the economical and financial situation. Questions appear when we notice differences between two countries, with similar features, with the absorption debut in the same period and taking the same steps for implementing the Structural Funds. A comparison between the implementing means, the existing barriers and the possibilities to overcome them, offer a clearer image about the country with a lower absorption rate concerning the perspectives of increasing that rate. In the case of our study, Bulgaria managed to overrun Romania in this phase of absorbing the Structural Funds. By this paper we prove that Bulgaria's advantages could be considered as good practice models to be followed by Romania in the future.

2. Romania, bad luck from the start?

The impact of applying the Cohesion Policy on Romanian ground can be observed from the macro economic analysis during the period of 2007-2013, when the European Union offers irredeemable financing by the Social European Fund (SEF), The European Fund for Regional Development (EFRD) and the Cohesion Fund (CF).

During 2007-2009 we can the impact of the Structural Funds regarding the macroeconomic indicators:

Table 1

Indicator	2007	2008	2009
PIB (%)	6,2	7,1	-7,4
Goods exports (%)	14,3	14,1	-18,1
Goods imports (%)	26,0	11,5	-35,7
Occupational rate (%)	58,8	59,0	58,3
Public deficit (%)	-2,5	-5,5	-3,5
Public debt (%)	13,0	13,6	22,5

Source: data processed by the National Statistics Institute

From Table 1 we can observe the evolution of the macroeconomic indicators in correlation to the absorption of the Structural Funds. We can consider the year of 2007 as the beginning, the accommodation period for Romania for the new perspective. The National Strategic Reference Frame is approved, the operational programs as well and the first applications for projects are made.

In 2008, most of the projects are applied, 90% of the planned operations being opened to the beneficiaries. Still we couldn't see a spectacular change regarding the macroeconomic indicators, due to two reasons: the negative impact of the crisis had been felt and the applicants didn't receive the money. The year 2008 can be considered the stage of writing and applying projects to the contracting authorities.

The year 2009 is maybe the most spectacular year from the considered period, because then several financing contracts had been signed and the payments towards the beneficiaries started to increase. This fact should have been felt proportionally at the level of the analysed indicators, but in reality things are different. This fact is determined by the more and more negative effects of the economical and financial crisis.

Though we should say that 3 years have passed already since Romania has become beneficiary of the irredeemable financing, we can only speak about 1 more encouraging and satisfactory year of this stage.

CSNR 2007-2013 beneficiates by 7 Operational Programs of an allocation of 19,213 billion Euro (EFRD - 8,976 billion Euro; SEF - 3,684 billion Euro, CF - 6,552 billion Euro) from the Structural Funds to which we add a co-financing of 5,6 billion Euro. In the graph we can observe the allocation CSNR per Operational Programs, as follows:

Source: data processed from the NATIONAL STRATEGIC REPORT 2009 regarding the implementation of the Structural and Cohesion Funds, January 2010

Theoretically, Romania must follow this distribution, according to the Graph 1.

In reality, things are a bit different. The 31st of December 2010, the total number of projects applied inside the 7PO had been of 24967, with a value of 29,86 billion Euro. At the same date, 6451 projects have been approved with a value of 14,39 billion Euro, the EU contribution being of 9,2 billion Euro. We continue the process and we arrive at 5012 financing contracts with the beneficiaries, having an eligible value of 12,77 billion Euro, with an EU contribution of 8,14 billion Euro, which constitutes 93,94% from the value allocated by EU for the period 2007-2010.

The topic becomes painful when it comes to the category of effective payments towards the beneficiaries, these representing pre-financings (1,17 billion Euro) and reimbursements (480 billion Euro EU funds and 69,7 billion Euro state budget co-financing), with a total at the 31st of December 2010, of 1,72 billion Euro. Comparing to the allocated period 2007 – 2010 we have managed to obtain a performance of 19,09%, and for 2007-2013 we talk about 8,62%.

These numbers are indeed alarming, the payments made to the beneficiaries being the cause of all the problems regarding the absorption of the irredeemable financing.

I cannot claim with certainty if Romania is aware of the gravity of these numbers but the National Strategic Report 2009, regarding the implementation of the Structural and Cohesion Funds, indicates the difficulties encountered and the solutions suggested.

The problems which block the raise of the absorption rate of the Structural Funds can be ranked at the authority, supervising and regulation levels but also at the level of the beneficiary.

The first category includes:

- the preparing of the portfolio for the projects - in 2007 CSNR had been approved, the promotional programs have been established and the financing lines were supposed to be opened; but here we face the lack of training of the authorities in offering information for elaborating a successful project;
- the launching of project requests – which should coincide to the guides of the applicants elaborated by the authorities;

this type of problem is justified especially by the lack of national strategies or even by the necessity of applying innovative strategies for selecting the projects;

- the evaluation, selection and contracting the projects – the biggest problem from my point of view; as argument I will offer a real example: you apply for a project at the moment t and you obtain the answer regarding the approval at the moment $t+2$; the contracting authority does not consider that at the moment t the beneficiary had a goal to achieve and with all the delay the goal could cease of being a priority or maybe the initial team does not exist anymore or maybe the beneficiary does not own the same financial resources for continuing to the initial direction;
- the institutional problems regarding the staff hired as supervising authorities; their lack of motivation, the stress and the great number of beneficiaries make the job more difficult, especially concerning the payment itself.

The second category of problems identified at the level of the beneficiary are really interesting:

- the problems regarding the public purchase proceedings – the lack of experience, the complaints, the assignation document, are just a few of the aspects which had made the implementing of the projects more difficult;
- the self financial contribution has been and still is the main barrier in financing the projects – especially during the economical crisis, when the lending conditions have been roughen for the small and medium companies;
- the inefficient communication between the beneficiary and the authorities lead to installing a real chaos – the beneficiaries send incorrect documents, with delays, and the authorities either give up or don't announce in time or oblige the beneficiary to make modifications duet o the mistakes made by the authorities.

These problems are considered as the main ones which put in danger the payment on time of the deserved sums towards the beneficiaries.

A first step made by Romania has been to acknowledge the dangers which, once identified, should be stopped.

There are various solutions offered for reducing them, but we are interested only in the theoretical part, a document sent to the European Commission in which we inform it about finding some ways to prevent the dangers. It is interesting to see in fact the way in which these solutions can increase the absorption rate of the Structural Funds.

The solutions can be divided according to each category of the identified problems.

For the first category of problems, identified at the institutional level, there have been found several pertinent solutions:

- the usage of the JASPERS instrument for technical assistance offered to the beneficiaries and to the authorities as well when confronted to major projects for compensating the lack of experience in this field;
- for launching the project requests in a more alert rhythm there have been offered technical assistance in elaborating the necessary documents and a more efficient communication with all the organisms involved;
- most of the solutions have focused on offering to the beneficiaries the results of the selection sooner: the externalization of the evaluation stage, the cancelling of the prioritising stage, the improvement of the applicants guides, the offer of clear and specific information, the simplification of the financing folders;

For reducing the difficulties encountered by the beneficiaries, the following solutions could be implemented:

- the modification of the law regarding the public purchase;
- financially, it has been decided to double the pre-financing rate from the eligible value of the financing contract so that the beneficiary should own enough resources for developing the activities;
- the Management Authorities have elaborated documents meant to facilitate the writing and the implementing of the projects: The Beneficiaries Manual, The Guide regarding the partnership relations.

3. Bulgaria, with ambition and perseverance

After the adherence to the European Union in January 2007, Bulgaria registered a significant economical growth. The PIB of the country has increased in real terms with 6,2% in 2007 and 6% in 2008, compared with an average annual growth of 5,6 during 2000-2006. The PIB per citizen has reached 41,3% from the medium level of EU from 2008, which has marked a raise of 4,8 percentage points compared to 2006. Thus, the country is about to achieve the ambitious goal of having a PIB per citizen of 51,2% from the medium level of EU in 2013.

Regarding the occupational rate, Bulgaria has reached the desirable standards. This rate registered an ascending trend, with a percentage in 2008 of 64% along with a low unemployment rate (smaller value than the EU average). This way, Bulgaria has managed to reach the target values suggested for the end of the program.

Regarding the good and services exports chapter, Bulgaria succeeds in impressing us with a growth of 5,2%-2007 and 2,9% in 2008. In 2009, the crisis appeared and produced a decrease of 12,8% from the exports.

From the presented values of the most important macroeconomic indicators we can declare that Bulgaria registers a real success in absorbing the Structural Funds. This aspect is confirmed by the achievement of the target values suggested by the strategic goals proposed at the beginning of the programming.

In table 2 we can observe the progress registered for fulfilling the CSNR goals, due mostly to the impulse gained in economy. The beginning of the CSNR application and of the Operational Programmes has been a privilege for increasing the investments in the basic infrastructure. This is one of the reasons why we can claim that in Bulgaria, the Cohesion Policy has been applied in a way able to generate positive aspects in the economical and social development of the country.

As in Romania's case, in 2007, 7 Operational Programmes have been approved and in 2008-2009 the solutions and the goals applied in CSNR started to be implemented. The Authorities who handle the

implementation of these Operational Programmes claim that Bulgaria's success is not due only to the absorption of these funds but also to the advance gained by the economy. They mention the difficulties they had because of the delay in approving the programs but also the challenge of the opening towards an unknown zone until that moment.

Table 2

Strategic Objectives	Benchmark	Baseline Value	Target Value	Value Achieved in 2008
1. Strengthening the competitiveness of the economy to achieve high and sustainable growth;	1. Percentage of GDP per capita from the EU average level	34.5 % 2005	51.2 % 2013	41.3 %
	2. GDP growth annual average	5% 2000-2006	5.73 % 2007-2013	6%
	3. Exports/GDP	60.8 % 2005	89.77 % 2013	60.5 %
2. Development of human capital to ensure higher employment, income and social integration;	1. Employment level;	55.8 % 2005	64% 2013	64%
	2. Unemployment level;	10.1 % 2005	7% 2013	5.6%
	3. Poverty risk	14.2 % 2005	13% 2013	14.4 %
	4. Population having access to water supply and sewerage	40.5 % 2004	66.46 % 2013	
3. Increasing the quality of human capital with a focus on employment;	1. Economic activity level -15-64 years of age.	62.1 % 2005	68.5 % 2013	67.8 %
	2. Share of the population aged between 25 and 64 years participating in training and retraining courses	1.3% 2005	5% 2013	1.3%
	3. Share of the population aged between 18 and 24 years with lower than secondary education not participating in any education and training forms	20% 2005	16% 2013	
3. Fostering entrepreneurship p.favourable business environment and good governance;	1. Labour productivity	3.5% 2005	5%	2.7%
	2. Foreign direct investment	EUR 3.2 bil. 2005	EUR 21.7 bil.	EUR 6.2 bil.
	3. Maximum number of days needed to incorporate a new company	32 2006	1 2013	2
	4. Maximum number of procedures needed to incorporate a new company	9 2006	1 2013	1

Source: Strategic Report of the Republic of Bulgaria for 2009

But with all these problems encountered at the beginning of the program, Bulgaria succeeded and had obtained satisfying results. Thus, in December 2010, projects had been contracted with a value of 2.946.576.235 Euro, in a percentage of 36,74%, the EU funds representing 2.463.312.622 Euro, respectively 36,91%.

For the payments category, at the end of December 2010 a value of 809.064.721 Euro, with a percentage of 10,09% has been reached. From the total of the payments made, the EU funds represent the sum of 680.779.320 Euro with a percentage of 10,20%.

This progress is due to the considerable efforts made by the Bulgarian government in organizing the habilitated authorities for implementing the funds, in view of handling them efficiently and transparently. For this there have been made actions for the optimisation of the institutional frame, the simplification of the proceedings, for the awareness of the public opinion and for improving the dialogue with the economical and social partners and with the European Commission.

An innovatory model and a good practice example is the Management Council of the EU Funds, created at ministerial level for consolidating the coordination in handling the funds. A unique centre for handling and controlling the EU funds has been created and transferred from the Financing Minister to the Administration Council of the Ministries.

From a legal point of view, in 2008 it has been adopted the Regional Development Law which rules the planning, the management, the monitoring and the control of the governmental policy for regional development.

All these measures have helped considerably the absorption of the Structural Funds, leading to a better monitoring and control.

Bulgaria has encountered itself lots of trouble in absorbing the Structural Funds being ranked at the level of the Management Authorities/Intermediary Organisms with an inadequate administrative capacity also at the level of the beneficiaries. The major problem is the lack of experience for facing such a challenge, especially when the Management

Authorities didn't have the experience for coordinating the pre-adherence projects.

The Bulgarian government admits they had serious problems such as:

- lack of financial resources for developing the projects by the beneficiaries, in advance;
- incomplete project folders;
- inefficient communication between the beneficiary and the evaluators;
- in some of the Operational Programs there have been applied too many projects which lead to delays in finalising the evaluations;
- delays in employing the evaluators for rushing the evaluation proceeding of the applied projects;
- delays in signing the financing contracts because of the complicated administrative proceedings.

The low rate of the payments made towards the beneficiaries is motivated, as a paradox, by the will of the Management Authority to be 100% sure of the legality and the eligibility of the expenses that have to be reimbursed. Aware of the problems and the suspended funds by EU during the pre adherence, they have included a series of control and audit activities for the financed projects. This leads to a slower recovery of the expenses made by the beneficiaries although the intentions of the authorities are different.

Besides, the beneficiaries are obliged to present a warranty of 100% for the payments received in advance. Because of the economical crisis they cannot warranty 100% not even for ensuring the mandatory co-financing by contract. The credits offered by the banks were ideal for helping the beneficiaries of irredeemable financing.

All these difficulties lead to a low rate in absorbing the Structural Funds, but the Bulgarian government offers remediation measures as well.

The measures taken for increasing the absorption of the funds aim at consolidating the administrative capacities of the institutions and at optimising the proceedings:

- the growth of the staff members inside the authorities which handle the implementing of the funds;

- the creation of an Audit Direction for EU Funds, a structure inside the minister;
- the coordinating structure of EU funds has been improved; 3 directions have been created: EU Fund Programming, EU Funds Monitoring and the System of Informing and Handling the EU Funds;
- training courses for the employees of the Management Authorities, of the Intermediary Organisms and of the beneficiaries of operational programs;
- projects financed inside OP "Technical Assistance", having as purpose the training of the employees of the regional administrations regarding the absorption of the Structural Funds;
- profitableness measures have been taken for each operational program in view of increasing the interest of the beneficiaries for obtaining irredeemable financing.

4. Comparison RO-BG

Table 3 OP Implementation as of 31.12.2010 Romania&Bulgaria

Operational Programme	Programme budget	Contracted		Payments	
		% implementation		% implementation	
		RO	BG	RO	BG
OP Transport	100%	18,28	29,92	1,03	5,62
OP Environment		52,88	27,35	7,27	6,96
OP Regional Development		65,82	51,34	15,78	11,58

OP Human Resource Development		90,30	47,36	13,66	8,91
OP Administrative Capacity		38,67	45,10	5,19	25,13
TOTAL		52,66	36,74	8,97	10,09

Source: data processed by the *National Strategic Report 2009 on the implementation of Structural and Cohesion Funds Romania for 2009* and *Strategic Report of the Republic of Bulgaria for 2009*

From the table 3 we can notice that Romania has been overrun by Bulgaria with

an absorption percentage of 10,09%. We have to observe that it didn't manage to overrun it regarding the chapter „human resources development”, Romania having a percentage of 13,66%.

From my point of view we should give all the credit to Bulgaria. This country has focused on its real needs and by this it has generated an economical growth as well. Romania has qualified people but this is not enough if the basic infrastructure is a disaster, if the public administration remained far in the back on the road of evolution.

5. Conclusions

Romania and Bulgaria are two countries who dream of a better way of living, without territorial, economical and social discrepancies compared to the other EU states. They are aware of the opportunity offered by EU through the Structural Funds but what counts the most is the manner chosen by each country for reaching the established goals. Bulgaria can be considered a good practice model in this domain because, by perseverance and ambition, it has managed to apply the best methods for raising the absorption rate. It had proved that it is mandatory to consider the real needs of the country without neglecting any field. In exchange, Romania preferred the development of the human resources and neglected the other sectors facing difficulties.

Budgetary Policy Rules and Their Efficiency in Limiting Public Debt's Proportions in EU Member States

Bilan Irina

"Alexandru Ioan Cuza" University of Iasi,
Faculty of Economics and Business Administration
irina.bilan@uaic.ro

Abstract

Ensuring the soundness of public finance and, implicitly, the sustainability of public debt, represents a major concern of public authorities in every country, including at European level. The literature suggests and practice confirms the possibility of using budgetary policy rules as a tool for achieving these goals.

The first part of this work is devoted to the analysis of the rationale for budgetary policy rules in European Union, mainly focusing on their action as a tool for preventing excessive public indebtedness.

We then briefly present the contents of the budgetary policy rules applicable to EU Member States, both at the national and supranational level and we analyze their efficiency in limiting public debt's proportions on the background of the recent global economic crisis, indicating some proposals for improvement.

Key words: budgetary policy rules, European Union, excessive public debt

J.E.L. classification: E60, H63

1. Introduction

The significant deterioration of budget balances and the important increase of public debts in the context of the recent global economic crisis have brought to the fore the issues of budgetary policy rules applicable in EU Member States, both at national and supranational level, as well as their efficiency in preventing excessive public authorities indebtedness.

Budgetary policy rules, also known as fiscal rules, are numerical limits or targets on the size of some budgetary aggregates that guide budgetary decision making process in

the sense of ensuring a permanent concern for financial discipline.

In practice, these rules can be designed in different ways, targeting the size of public debt (limit of the gross or net public debt as a share of GDP, etc.), budget balance (balanced budget, limit of the overall or structural budget balance as a share of GDP, golden rule, etc.), budgetary revenues or expenditures. Also, budgetary policy rules can be established by law, constitution, international treaties or can be the result of budgetary procedures.

2. The rationale for budgetary policy rules in EU Member States

The main objective of every budgetary policy rule is to maintain budgetary discipline, in other words to prevent unsustainable budget deficits and the over indebtedness of governments to arise. However, other positive effects can also be registered, such as strengthening economic policies coordination between different levels of government and reducing the uncertainty regarding the future conduct of budgetary policies.

Avoiding high public debts is a great concern for every country, as a result of the numerous negative consequences that such a situation may pose to economic and social activities. Thus, excessive public debt accumulation adversely affects long term economic growth, reducing the consumption possibilities of future generations. Large scale public debts also increase economic vulnerability to various shocks (e.g. severe recessions), reducing the ability of governments to use budgetary policy instruments to mitigate their impact. Last but not least, high public debts may force governments to accept higher inflation to reduce their burden (repudiation through

inflation) or to declare themselves insolvent, in both cases the economic, social and political consequences being disastrous.

Although maintaining public debt within acceptable limits and, most generally, ensuring the soundness of public finance should represent a priority of the budgetary policy in every country, it plays a special role in EU Member States, as they are either preparing for euro adoption or have already become members of the euro area. Several arguments can be invoked in this regard.

First, maintaining an acceptable level of public debt is a prerequisite for ensuring the stability of prices and promoting sustainable economic growth in Europe.

Second, as countries which adopt the single currency give up their monetary policy competences in favor of the European Central Bank, national budgetary policy instruments remain the only instruments available in order to mitigate the impact of various economic shocks and excessive public debts exert constraints on their use.

Finally, excessive public indebtedness also proves to be particularly important in EU Member States because of the negative externalities that it generates, as there is high risk to be affected not only the macroeconomic stability of the indebted state but also that of other EU Member States, even putting into question the continuation of the European construction and of its central pillar, the single currency. The importance of these issues was revealed in the context of the problems recorded by Greece, Ireland and, more recently, Portugal, calling for the joint action of other member states in support of the one in difficulty. The implementation of functional budgetary policy rules should reduce the risk of bailout of over indebted countries by European institutions.

The literature also indicates other mechanisms that can be used in order to limit public debt's proportions and prevent the adverse effects that the over indebtedness of governments generates [10]. In this respect, we should consider the mechanism of market discipline, focused on market forces as factors able to prevent the abuse of public indebtedness. However, this mechanism has proved itself not to be perfectly viable in the European area, the recent economic crisis highlighting the lack of credibility of European institutions' commitments not to

bail out troubled member states (a prerequisite for the proper functioning of this mechanism), especially when they play a major role on European markets.

Budgetary policy rules can work towards preventing the over indebtedness of public authorities either directly, by setting numerical limits on the size of public debt as a share of GDP, or indirectly, by limiting the possibility of incurrence of factors that can lead to debt accumulation, mainly budget deficits.

Thus, both public debt rules and balance budget or expenditure rules can help ensure a sustainable public debt. However, it is considered that the debt ceilings exercise constraints on governments especially when public debt is substantially approaching the limit, which is often too late. Controlling budget deficits can also prove to be ineffective in limiting the amount of public debt when the deficit measure used is not comprehensive or when other factors than budget deficits have an important contribution to the accumulation of public debt (i.e. the assumption of private liabilities as public liabilities). It is therefore advisable, in order to prevent excessive government indebtedness, to combine, in practice, the limits on the size of budget deficits with limits on the maximum level of public debt.

3. Short survey of budgetary policy rules in EU Member States

Budgetary policy rules have been established in EU Member States both at national and supranational level.

Relations of complementarity exist between the two categories of rules, as they complete each other and act together in order to reach the common objective of strengthening budgetary discipline and ensuring the sustainability of public debt in Europe. First, the rules established at national level, even by the Constitution, can be amended if a new political majority meets. Establishing rules at a higher, European level (rules which cannot be changed unilaterally by the initiative of a single Member State) helps strengthening the credibility of similar rules adopted at national level. Second, the existence of national rules, adapted to the specific realities of each state concerned,

increases the chances of success of the rules established at European level.

3.1. European budgetary policy rules

Budgetary policy rules exist at European level starting with the Treaty of Maastricht, signed in February 1992 and setting the foundations of the European Monetary Union. It establishes maximum limits for budget deficit (3% of GDP) and public debt (60% of GDP), designed as convergence criteria for adopting the euro.

The need to maintain budgetary discipline and avoid the over indebtedness of public authorities after adopting the single currency called for the extension of these criteria to EMU Member States, by the Stability and Growth Pact, adopted in 1997 and reformed in 2005. In summary, it establishes two categories of rules, as follows:

A) Budget balance rules

- The structural budget balance must record, over the medium term, a surplus or deficit of no more than 1% of GDP. Its actual size is determined by reference to the specific conditions of each country (growth potential, cyclical position, ongoing structural reforms, share of public debt to GDP, etc.).
- The overall budget deficit should not be excessive, not exceed 3% of GDP, unless exceptional circumstances are recorded (negative economic growth or a prolonged period of slow economic growth, pension systems reforms, significant public investment spending and other relevant circumstances).

B) Public debt rules

- The gross government debt should not exceed 60% of GDP or, if this level is exceeded, it should decrease at a satisfactory pace.

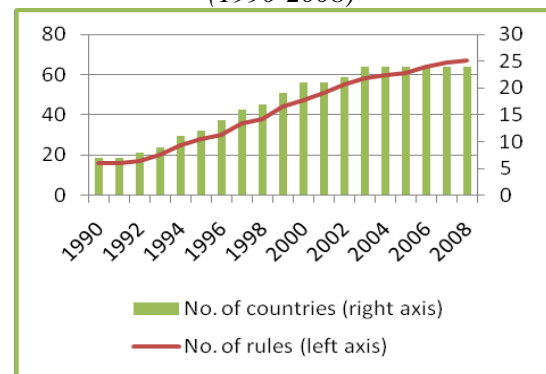

The Stability and Growth Pact also provides corrective measures that can be applied when excessive deficits incur, ranging from recommendations made by the Council of Ministers to Member States to correct the situation to reviewing the loans policy of the European Investment Bank towards the undisciplined country or even financial sanctions in the form of deposits without interest or fine imposed to the concerned Member State.

3.2. National budgetary policy rules

The introduction of national numerical rules, complementary to the supranational ones, is supported even by the European institutions. For example, in the report on reforming the Stability and Growth Pact in March 2005, the European Council asserted that *"national budgetary rules should be complementary to the Member States' commitments under the Stability and Growth Pact"* [13].

Using budgetary policy rules as a part of the national budgetary frameworks in order to prevent the unsustainable growth of public debt is a relatively recent idea. However, the number of such rules and the number of countries from European Union having implemented them have increased steadily over the past two decades, as can be seen in figure 1.

Figure 1. Number of countries having a budgetary policy rule and total number of rules in force in EU Member States (1990-2008)

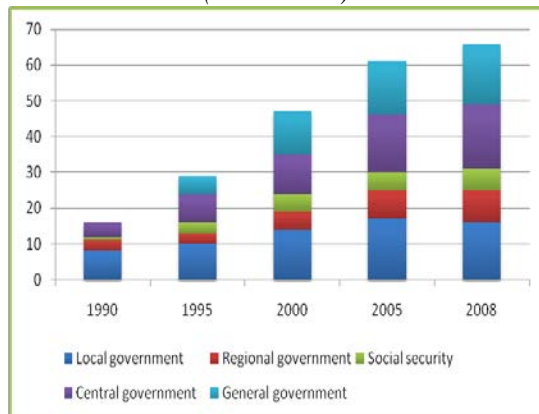

Source: [4]

The total number of budgetary policy rules implemented at national level in EU Member States has increased from 16 in 1990 to 61 in 2005 and 67 in 2008. Similar developments can be noticed when considering the total number of countries implementing these rules, only 3 of the 27 EU Member States (namely Cyprus, Greece and Malta) having no such rules at the end of 2008.

As for their coverage, budgetary policy rules have been implemented at all levels of government (see figure 2). However, in 1990 most numerical rules concerned local and regional governments (11 out of 16) and there was no rule for the general government,

the situation changed later on. It can be observed, especially since 2000, a sharp increase in the number of rules that apply to central and general governments, in 2008 35 out of 67 rules concerning these sub-sectors.

Figure 2. Number of budgetary policy rules by sub-sector in EU Member States (1990-2008)

Source: [4]

Out of 27 EU Member States at the end of 2008, 11 had rules for the general government and just as many only for the central government. Only Belgium and Romania had such rules neither for the general nor the central government sub-sectors.

Or, a larger coverage of the budgetary policy rules can be considered as a prerequisite to ensure their high efficiency in preventing unsustainable public debt growth, especially when access to borrowing is permitted to all levels of government.

In relation to their content, most of the rules are budget balance rules, as can be seen in figure 3.

Figure 3. Number of budgetary policy rules by type of rule in EU Member States (1990-2008)

Source: [4]

In 2008, out of the 67 existing rules, 25 were budget balance rules (more than one third), only 18 debt rules and even less revenue and expenditure rules.

The data presented indicate that rules aiming at controlling the size of the budget deficit, as the main factor contributing to public debt accumulation, are most often preferred by public authorities at the expense of rules directly limiting the stock of public debt. However, as we have already seen, the best results can be achieved, in practice, when these two categories of rules are combined. In EU, of 24 countries with national budgetary policy rules, only nine combine balance budget rules with debt rules and 3 expenditure rules with debt rules.

Also, most of the budget balance and public debt rules are applied at lower levels of government, such as regional and local governments. Central governments and social-security authorities mainly resort to expenditure rules.

Getting positive effects as a result of the implementation of budgetary policy rules depends not only on how they are built and on their coverage, but also on the existence of appropriate monitoring institutions as well as enforcement mechanisms. In this respect, according to European Commission's appreciations [7], at the end of 2008, many of the budgetary policy rules in place in EU Member States lacked an independent monitoring institution and had poor enforcement mechanisms in case of non-compliance.

4. The efficiency of budgetary policy rules in limiting public debt's proportions in EU Member States and solution for its improvement

An efficient budgetary policy rule should prevent governments from running high budget deficits and accumulating unsustainable levels of public debt. However, this is not the case of many EU member states.

On the background of the recent economic and financial crisis, public debts grew rapidly in many countries, surpassing their sustainable level. This was the mixed result of GDP contraction, high budget deficits and financial sector support schemes.

It can be noticed, from the data presented in table 1, that many EU Member States currently have excessive public debts, well above the limit of 60% of GDP. In 2009, 12 out of 27 states exceeded this threshold and their number is expected to grow to 14 in 2011. The situation looks even worse if we also take into consideration the implicit debts, escaping the European institutions' official assessments on public debts.

Table 1. Gross public debt as % of GDP in selected EU Member States (2001-2011)

Country	2001	2003	2005	2007	2009	2011*
EU	61.0	61.8	62.7	58.8	74.0	81.8
Euro area	68.1	69.0	70.0	66.0	79.1	86.5
Belgium	106.6	98.5	92.1	84.2	96.2	100.5
France	56.9	62.9	66.4	63.8	78.1	86.8
Germany	58.8	63.9	68.0	64.9	73.4	75.9
Greece	103.7	97.4	100.3	105.0	126.8	150.2
Ireland	35.5	30.9	27.4	25.0	65.5	107.0

*estimations

Source: [3]

This situation is certainly not specific only to bad times, large public debts have been recorded in many developed countries before the crisis began, which indicates that governments have not taken advantage of the favorable economic circumstances to make enough budgetary savings. Thus, the average euro area public debt has exceeded the threshold of 60% of GDP every single year since 2001.

The development of public debts, both before the onset of the global economic crisis and when its effects became visible and called for action, demonstrates that the current budgetary rules system in EU Member States, both at the national and, especially, European level, is far from being an optimal one. It should, therefore, be reformed, to correct its design and implementation deficiencies. Some basic directions should be considered:

a. *Public debt rules should be more widely used*, possibly in addition to budget balance, revenue and expenditure rules. At the

supranational level, where the Stability and Growth Pact includes such rules concerning the size of public debt, it is important to increase their importance within the excessive deficit procedure.

b. *Public debt indicators in public debt rules should be reconsidered so that they include implicit debts* (such as long-term pension commitments or guarantees granted by public authorities to private entities). Numerous studies have shown that these liabilities are sizeable in EU Member States and may represent a real threat to long-term public finances sustainability on the background of an aging population.

c. *The scope of the national budgetary policy rules should be expanded so that they include all government sub-sectors* (central government, state governments, local governments and social security). As for public debt rules, they should be introduced for all public authorities that have the ability either to directly borrow to fund public expenditures or to guarantee private loans, but especially for central governments.

d. *Budgetary policy rules should be redesigned so as to ensure a high degree of sensitivity to economic circumstances*. Most rules existing at national level set fixed numerical targets for budget aggregates, which cannot be adjusted depending on the economic situation. Thus, they proved to be procyclical, allowing governments to spend and borrow more in favorable times and demanding for austerity measures when the economy became weaker. Though, budgetary policy rules must be adjusted depending on economic circumstances, allowing public authorities, during a recession, to take action in order to support economic recovery, to promote budget deficits, borrow to finance them and, thus, accumulate public debt. Conversely, in periods of sustained economic growth, budgetary policy rules should be adapted to force governments to save money and to substantially reduce the size of their public debts. This would create sufficient margin of maneuver to allow for the support of the economy in difficult times, without generating an unsustainable increase in budget deficits and public debt.

e. *Enforcement mechanisms should be introduced or strengthened, there where they already exist*, as they proved to be insufficiently strong, both at the national and

European level. For example, the Stability and Growth Pact proved not to be enforceable enough against some big countries like Germany or France, which managed to promote excessive deficits for several years without being punished.

5. Conclusions

The need to avoid excessive indebtedness of public authorities is undeniable in every single country, as a result of the adverse economic and social effects that such a situation would generate. Ensuring the sustainability of public debt is, however, of increased importance in EU Member States, as they are either preparing or have already adopted the single currency, due to the additional constraints that the membership to a monetary area imposes.

Using budgetary policy rules is one of the mechanisms that the literature indicates in order to achieve this objective. Such rules exist in EU both at the national and supranational level. This work revealed, however, that the current system of rules in EU Member States is far from being optimal, as he failed to prevent the unsustainable growth of public debt in many countries, especially the developed ones.

This doesn't mean that budgetary policy rules should be removed, as no better alternative yet exists. However, they should be reconsidered, meaning that some deficiencies should be corrected, among which we can mention the low importance granted to public debt rules, the insufficiently expanded scope of the rules, the lack of sensitivity to economic circumstances and, mainly, the lack of or poor enforcement mechanisms.

Managerial Accounting Principles and Cost Calculation Used by Economic Entities in the Coal Mining Industry

Boca (Rakos) Ileana – Sorina
Vătășoiu Cristian Ionel

crissgiovanni@yahoo.com

Abstract

Considering the specialized work in managerial accounting, this paper aims to show which cost calculation principles are actually applied in the coal mining industry today. The methodology used in this scientific approach is of qualitative nature, using the following methods: direct observation and interview.

Key words: principles, management accounting, costing, coal mining industry

J.E.L. classification: M41

1. Coal mining industry in Romania – general view

The industry is a branch of the material production and of national economy, in which widely occur the exploitation of natural assets and their (as well as others) transformation, in means of production and consumer goods. (Definition given to the concept of industry in the Explanatory Dictionary of Romanian Language, Universal Encyclopedia Publishing, Third Edition revised and enlarged, year 2009)

Industry includes: mining industry, manufacturing industry, electricity, gas and water. The industry occupies an important place on the national economy, covering unlike other branches of the economy, the demands of all sectors of activity as the carrier of most advanced production relations.

Coal mining industry is a branch of industry whose main objective is to produce electricity. Coal, as mineral fuels, along with other natural resources constitutes the country's primary energy sources, with which

electricity is produced. Electricity is considered the main branch of the national economy.

In our country there are three categories of coal:

✓ *lignite*, also called brown coal because of its color is the least changed and has the lowest carbon content, i.e. about 30%. During combustion it emits much smoke and relatively little heat;

✓ *coal* is the most widespread coal and generates the most heat. This type of coal has usually alternating dark and glossy layers, the shiny bands being based on wood and the dark layers have been formed from the remains of plants that have rotted over time.

The coal contains a softer compound, like charcoal, which is to "dirty" during handling;

✓ *hard coal*, known as higher coal which is composed of 98% carbon, is very hard to extract and clean during handling, burning with high and hot flame. This coal emits less smoke and is very difficult to ignite.

Coal is the richest deposit of fossil fuel. Known world reserves are estimated to be sufficient for a further period of 200 years at a current rate of consumption. Many experts consider that there is worldwide, about 15 times more coal remained undiscovered. Once discovered the deposit has been exploited in depth. Today, exploring for coal is one of the basic activities of geologists. They know from experience, the type of land under which coal could be found; especially in areas with rocks from coal period. The thickness of a coal bed can vary from a few centimeters to several meters and whatever

thickness it has, there are two types of mining: surface and underground mining.

2. Principles of management accounting and cost calculation used by economic entities in the coal mining industry

Accurate and precise calculation of costs, implies the need to solve some basic theoretical issues, both for accurate budgeting of costs, as well as for strict observance of theoretical and methodological principles that should form the basis for determining costs as well: the principle of determining the calculation object, the principle of establishing the method of calculation, the principle of organizing the accounting calculation in conjunction with the other economic calculations (statistical, forecasting), the principle of separating the economical and financial indicators of costs calculation by type of activity, the principle of expenditure timing, the principle of space delimitation of costs, the principle of delimitation of productive expenditure from the unproductive, the principle of demarcation of expenditure between output and production in progress.

The organization of management accounting and cost calculation of an economic entity of coal mining is based on a set of principles, including:

✓ the principle of delimitation of the production costs in space

This principle is a space (territorial) separation of expenditure, i.e. a separation of them on production sites (mines, slaughter lines, phases of work, cutting, etc.) where they are formed. *The principle of delimitation in the area of the production costs*, in fact is nothing more than sectorization of production process in a manner most appropriate to the needs of accounting and cost calculation, avoiding the record several times on the same charges in several places (doubling records and calculations). In the economic entities of the coal mining industry this principle refers to the delimitation of production costs, incurred in a certain period of management by a coal-mining in the area, on cost places (supplying with raw materials and consumables necessary for mining; preparatory work in the mining field, mine

ventilation, maintenance of the main process with energy, water, steam and compressed air, repairs and maintenance of mining machinery, means of transport to the surface and interior, administration and sales) that take place within the boundaries of mining coal in some spaces called "places". In these places there are involved consumptions of materials, time, labor and machinery (depreciation), thus becoming "expenses places". The concept of production sites is not only referring to the main parts of the technological process (extraction itself), but also to all other ancillary and service processes of extracting coal. Establishing spatial production sites usually occurs on a plan of organizing the production process, prepared according to the principles of techno-economic rationality. Taking into account that in terms of technology, the production process can be divided into a number of elementary works and operations, not all places of production can become at the same time places of expenses. The notion of spending is closely linked to the production place, but not to be confused with one another. In practice it is quite difficult for most small places in the production process, corresponding to an operation in detail, also to become places of expenditure, in the accounting sense. Consumption of materials, labor, equipment etc. can not always be traced, in accounting terms, on the smallest production sites. Therefore, in practice it is often necessary to group several production sites in one main place of expenses. The larger size an economic entity in the field reaches, the more important the sum of consumptions becomes and the more it increases the spending places. Typically, these expenses places overlap costs of production sites, from a certain size, assessed by the managers of the economic entity to be useful in the accounts and the calculation of production costs. A fundamental distinction between production sites and places of expenditure is that, while the former always have a material existence, representing the spaces inside the production process through different processes, the places of expenditures, as required by accounting needs and cost calculation, may sometimes have a functional and abstract character. The place of production, as productive unit, can not always be a place of expense and

calculation. It is not a notion of accounting, statistics or calculation type it is usually understood as a unit defined in terms of space.

The number of production sites in a coal mining may be higher or lower, according to the detailing degree of work phases and other supporting processes of the mining activity. The larger the number of production seats corresponding to production operations in detail regarding the production process, the more the possibilities of accounting and statistics increase and the control of the mining operation becomes more effective, but this becomes more expensive. Therefore, the manager should always consider the necessary degree of organization of records, taking into account the size and specifics of the mining.

The premise of this approach on the issue of expenditure delimitation on places is the need to know the best places to carry out the production process. In practice, this is not an easy job, because you have to take account of technical factors and management's operational needs, i.e. to determine those places where costs have incurred and where, therefore, they can be recorded and pursued with clarity and precision.

To delimit places of expenditure there may be taken into account several criteria, namely: space, i.e. the material existence of the place of expenditures; the function it performs for the mining, the need of production cost calculation, etc. The space criterion remains the most important criterion for determining the costs of production, because it allows a precise determination of the places of expenditures, the way they are cycled during the production process. The functional criterion is based on determining the production costs on expenditure places, based on fundamental organic mining operation: supply, mining, administration and marketing. Regarding the space delimitation is deepening primarily in coal mining sectors, distinguishing between the productions sectors, ancillary and annexes sectors, the administrative and managerial sector. Within the productions sections, the demarcation of spending according to the space criterion may deepen according to the brigades, the methods of coal mining, production centers and responsibility. This location of costs is important for forming the production costs,

of the total cost, as well as for establishing the responsibilities regarding each place generating expenses. Thus, the costing calculation on places is important both from a formal point, namely the way of collecting expenditure on places generating consumption and their distribution on bearers of costs, as well as from the operational aspect, in terms of effective management of work done in these expenditure places on the liability of managers of such sites. Regarding the calculation needs the delineation of expenditure on costs areas, get a more complex character than in the two cases above, reaching a combination of the two criteria, spatially and functionally. The difference between the criterions regarding the calculation needs and the other two criteria, spatially and functionally, is that while the areas of expenditure, limited according to the needs of calculation, have a temporary character, the spending areas, limited according to the two criteria, spatial and functional, are of permanent nature. The space criterion and the functional criterion, follows closely and in real the technological process, while calculation is an abstract criterion, which in practice creates some inconsistencies between the technical and accounting side. Hence here is sometimes a problem in the organization, consisting in joining both the sharing of areas on technology criteria with sharing on accounts, also taking into account the needs of calculation.

✓ the principle of costs separation relating to coal extraction from costs that are not related to it

According to this principle a post-calculation can not be conceived in lack of the costs evidence in the accounting really corresponding to the actual consumptions of labor, of means of production and labor items. In order for the spending accounts to rightly reflect the whole economic activity of mining it is necessary a separation of costs of production from costs which do not affect production. Due to this principle, from the costs of coal mining are separating the costs for investment works and those involving non-industrial activity. Separately, there are also highlighted entertainment expenses, expenditure on social and cultural activities, etc.

In other words, this principle seeks delimitation of expenses recoverable by the cost of production (operating expenses) from the costs of other activities (financial, exceptional activities, etc.). Failure to observe this principle determines the distortion of production cost and leads in some cases even to hide some weaknesses in mining activity.

✓ principle of the delimitation of productive spending from the unproductive

Under this principle, including the production expenditures into the costs must take place within the fiscal period of production (coal mining) to which they relate irrespective of the time when such charges have been made. Taking into account the principle of delimitation in time, production costs are divided into three groups: prepaid expenses, current expenses and commission expenses. Some expenses such as subscriptions to professional periodicals, taxes on land and buildings, costs of mining, overburden works etc. shall be made in the current period and concern several periods of management. The current expenditures are those which take place during the management period, i.e. the production achieved during a calendar month, most part of production being costs of the current category.

Provisioning expenses are those that are included in the cost of production in the current period by creating commissions, but practically they are made in future periods being supported by these provisions. This includes: preliminary repairs, routine repairs, technical revisions and current repairs to tangible assets, etc. In the management accounting this principle is achieved through the accounts of Group 92 "Calculation accounts" and 901 "Internal settlement expenditure". By strictly applying the principle of timing of production costs, there are removed the causes that can monthly cause large swings in the cost of production, practically into management periods. Demarcation of time is important for comparative analysis of expenditure for specified periods in terms of performing the program of reducing the production costs.

✓ the principle of demarcation of productive expenditure, from the unproductive.

The compliance with this fundamental principle of cost calculation ensures the determination of a cost corresponding to reality, both in size and structure. This principle is based on the necessary economical differentiation of productive expenditures, which are also value creating, from unproductive expenditures, which do not add any value to the product. The unproductive expenditures encountered in a coal mining are determined, in general, by: consumptions exceed of specific mine timber, electricity, metal wire, explosives etc.; the use of materials of different quality or other dimensions to those provided in the rules, the miners' salaries exceeding the planned expenditure due to deviations from the established technological process; losses caused by interruption of the technological process (fires, floods, land subsidence, etc.). All these non-productive expenses are included in the production cost, if they occurred during the production process, in order to reflect the full amount of expenditure and the way of managing the resources within the mine. In fact, these expenditures are reflected in the actual cost of the product in the category "indirect production costs" (common costs of the department) and "general administrative expenses" of mining, which in turn include several cost components, including the unproductive ones, without being reflected in a distinct position in the structure of the production cost.

The influence of these costs is also reflected in the level of the other economical efficiency indicators, by lower profit and profitability in mining. Therefore, we believe that these expenses must be followed separately in a distinct calculation item, in order to identify and remove the causes that bring them about.

✓ the principle of management accounting and calculation of the costs in accordance with the indicators used in the budget activity

According to this principle it is necessary, both in budgetary work, and in the accounting to be considered the same form of technical and administrative organization, the same elements of the technological process, to be used the same principles of grouping and sharing production costs. Within this

overall framework of particular importance is the consistency between budget and accounting related to: budgeting and following expenditures on products and production sites, using in accounting of the same calculation items in the calculated budget etc.

If we consider, for example, the budget for general and administrative expenses of coal mining, it includes budgeted general and administration expenses on categories of expenses (interest expenses, general expenses for gratuities, household administrative expenses, etc.) and within these on types of expenses (salaries of management personnel, depreciation of fixed interest, automated data processing, land taxes, office supplies, etc.). All these expenses are accounted in account 924 "General expenses of operating activities" in the analytical on categories of expenditure (9241 "General interest expenses", 9242 "General expenditure on gratuities, social activities etc." 9243 "Administrative and household expenses" 9244 "Maintenance and management costs," 9245 "Guard and civil defense expenses," 9246 "Unproductive expenditure," 9247 "Other expenses heard on the results," 9248 "Other general expenses of the enterprise") and within these on kinds of expenses (92411 "Leading staff salaries", TESA, service, health insurance and unemployment fund," 92413 "Depreciation of fixed interest," 92417 "Land Tax", 92431 "Office Supplies", 92433 "Expenditure PTTR" 92441 "Expenses for heating," 92451 "Guard unit property (materialized security)", 92461 "Covered provisions" 92471 "Debts taken over by mayoralties" 92481 "Other expenses (approval for operating preliminary for 2010 expenditures for treatment and sports facilities, auctions, unwarranted subsidy etc.). By using the same methodology for expenditure accounting like for the budget, there are being created the conditions for it to become an effective means of control on the way of compliance and stay within budget of production costs and on the burden of reducing them and also to provide a wide field for analysis of the production activity of coal mining.

3. Conclusions:

Mining was considered until 1989 the most important branch of national economy and the coal mining industry was considered the most important sub-branch, as cataloged on the large number of employees, being ranked before the production of oil, natural gas, metal ores and other mining activities. Economic reform in the mining industry after 1990 saw the most dramatic industrial restructuring processes undertaken at national level, a process that took a great extent also in the European Union in the context of the growing global market price of metals, and about 70 % of European manufacturing industry depends on the extracted substances. Therefore there must be identified the best opportunities of management and the best costing calculation methods, so that economic entities in the coal mining industry to become viable and not be closed.

Qualities and Requirements of the Financial – Accounting Information

Boghean Cristina Iuliana
University of Craiova, Faculty of Economics
cristinaboghean@yahoo.com

Abstract

Accounting information is used in most of the decision-making processes of a company; therefore measuring its quality has become a matter of present interest. The quality of information largely determines the performances of the financial – accounting department, as well as the successful reaching of the company's goals.

Any reflection on the concept of quality in accountancy requires prior clarification of the purpose corresponding to the relation between the accounting information, its users and the economic reality described. Defining the generic qualities of accounting information must cover all user needs for a particular situation in contexts of wide variety.

Key words: information, requirement, quality, accountancy

J.E.L. classification: M41

The quality of information largely determines the performance of the financial – accounting department, as well as the successful reaching of the company's goals.

The quality goals in accountancy express a specific set of characteristics, assumed by the accounting staff of any entity. In this sense, four approaches are to be discussed upon:

- the satisfaction of the needs and expectations of all accounting information users while complying with rules and the professional ethics;
- the continuous improvement of the provided accounting information, including all methods of communication;
- the efficiency of production and communication for the accounting information (provision of service according to ISO 9004.2);

- taking into consideration the requirements of both the society and the business environment.

Any reflection on the concept of quality in accountancy requires prior clarification of the purpose corresponding to the relation between the accounting information, its users and the economic reality described.

Accounting information does not provide a guaranteed benefit to all its recipients unless found in a working environment which expressly calls for proper application of the accounting norms. Accounting regulations describe all the conventions applied in order to express, determine, measure and present the economic reality in accounting situations.

Precisely from this perspective are now approached the intelligibility of the accounting information and the consequences of the strict compliance of regulations. Users are presumed to have sufficient knowledge of accounting conventions and interpretations that characterize the content and form of certain covered or of internal use documents for the company. This aspect remits logically to the regulations defining and to the responsibility of designing accounting documents easy to be understood by the users.

Regulations on the quality of accounting information include not only the external rules that apply to all bodies or companies providing accounting information, but also internal specifications that can be additionally provided in order to meet specific needs for management and accounting documents. External rules are made up of all conventions and rules of accounting in the broad sense of the doctrine, regulation or professional practice. These accounting conventions essentially refer to:

- fundamental postulates, basic accounting principles and accounting nomenclature (accounting and financial fields, which

are in effect normalizing the conceptual framework of accounting);

- accounting guidelines for identification, measurement and presentation (IAS, IFRS, EU directives, national accounting law), the definition of which belongs to national or international legislature that determines the field and conditions of use;
- specific regulations of an activity or a category of legal, administrative, technical, economic or financial operations, with direct and indirect accounting consequences.

Accounting conventions and rules of foreign origin are complemented by internal specifications. They clarify the application of the accounting conventions and rules inside the company, as well as their organization in order to meet the special needs of accounting information users and administration.

The proper application of accounting rules, either these of external or internal origin, should be ensured based on the company's "accounting quality" system. In fact, the proper application of the accounting rules ensures compliance with the rules applied in the drawing up of documents; also, it determines the continuous improvement to meet user needs.

The company's "accounting quality" system helps to organize the strategy in order to achieve two key goals, namely compliance and improvement.

Defining the generic qualities of accounting information must cover all user needs for a particular situation in contexts of wide variety. This is necessarily confined to a major methodological difficulty that comes from multiplying the different categories of external or internal users, as well as from the variety of accounting documents.

Users are distinguished one from each other by the nature of their decisions, the methods they use, the information they possess or may obtain from other sources, as well as their ability to manage this information. In order to be useful, information must be tightly related with the users and the taken decisions or the followed goals.

The user can be external (independent) as referred to the company which provides accounting information; nonetheless, this

user can maintain an affiliation status (staff, employees) or a private contractual relation (banker, contractor), respectively.

There are two lines of reflection to identify the characteristics of generic quality for the accounting information [1]:

- deduction from the inventory of various supports and forms of accounting information, of common and representative characteristics, as well as of expectations belonging to different user groups;
- induction based on the user's generic conception concerning the accounting information of the characteristic variations of confidence every user assigns in the so-called "accounting label" (denomination) corresponding to the information.

The second methodological approach consists of searching for generic attributes of accounting information quality; this approach is preferred because reflects better the vocation of universality that privileges the accounting quality measuring. Based on this perspective it is possible to develop other approaches, methods or tools which ensure the fact that the accounting information available to users is credible.

The rules and the works of some authors emphasize the importance of the accounting information's quality measurement system. In principle, these rules should allow:

- to determine the satisfaction level of users' requirements (specifications) for services available to them;
- to discover and record non-conformities and malfunctions in processes;
- to quantify the effect of corrective actions after the analysis of these deviations;
- to monitor results improvement and processes efficiency.

The Order of Chartered Accountants in France proposes an evaluation system consisting of nine attributes of accounting information quality; these nine attributes take into account all the legitimate confidence expectations of the users;

For this approach, the generic attributes are the following ones:

- relevance is a specific feature to decisions or use (prediction value and confirmation value).

- reliability refers to the alteration level by appearance of errors, omissions, or unauthorized manipulation (completeness, data integrity).
- duration/ Availability represents the implicit or explicit availability date to be useful in making decisions or behaviour modification.
- clarity means presentation or content that allows a direct and quick understanding, without risking inappropriate interpretation of the facts or economic reality described.
- flexibility is the ability to adapt in order to meet explicit or potential new needs.
- verifiability/ Sampling is the correlation between elements of financial statements or accounting documents and real operations or facts involved.
- compliance with regulations expresses compliancy of conventions and rules of general accountancy and internal complementary specifications.
- neutrality is absence of the appreciation elements introduced by the influence of a previous searched result in the expression of a financial situation, economic facts or activity of a company.
- comparability means measurement and identical presentation in consecutive years balances for status and activities of companies with similar economic characteristics.

This reference system reflects a convergence in terms of professional accountants leading expertise or reflections in the field of quality accounting work.

Accounting information is reported to external users by means of financial statements published by the company. The conceptual framework of quality accounting work defines and sets the parameters enabling the characterization of the accounting information usefulness. These generic qualities are distinctive and shall not be confused with the fundamental postulates, the basic principles and the accounting guidelines for identification, measurement and presentation, which are part of the accounting references arising from the conceptual framework of accounting.

The conceptual framework of accounting information quality must be sufficiently opened as to meet not only the expectations

of external users (investors, tax authorities) towards the regulated accounting information, but also to integrate the particular concerns and needs of all other categories of users.

Currently, the conceptual framework of accounting [2] is oriented to accounting information which should give an accurate image of the economic reality described by a proper application of all accounting conventions. This conceptual framework describes the basic objectives assumed in accounting. This will ensure consistency in procedures for the establishment, measurement and presentation including the design of specific expressions for some economic or legal categories or for new financial instruments.

In my view, all concerns regarding the quality and requirement of the financial - accounting information are imposed by its variety and its use in the foundation of most decisions aimed at improving the efficiency of each activity within the company. Hence, the need for information to be of high quality: to be truthful, objective and valid. These features can be provided through specific activities such as:

- consultation of the original data sources;
- correct interpretation of the control on the occurrence of the phenomenon recorded in documents;
- consultation of the most recent data sources;
- comparison of the same information held by different sources (accounting data, statistical data).

In order to ensure data information, the financial and accounting information subsystem must operate on the basis of some requirements, namely:

- to correlate the need for information with the goals of the managerial activity;
- to correlate the information subsystem with the managerial process;
- to establish the relation between the information subsystem and the company's organizational structure;
- to select the information in order to ensure an effective match between the real information needs and the information provided by the information system;
- to provide the records' quality and data processing operations;

- to correlate the flexibility and adaptability of the information system to the dynamism of all problems faced;
- to provide concrete and accurate data, enabling an early assessment on the decision effects;
- to continue the information while complying uniformity and opportunity;
- to use mathematical methods for identifying, structuring and quantifying past and present events in order to predict the future;
- to combine financial data with data regarding the core activity for an accurate assessment of achievements;
- to provide information to a certain level; the degree of detail has to correspond to the hierarchical level which is addressed;
- to present information in a way that avoids additional interpretations or subsequent analysis;
- to make an efficient use of staff and technological equipment in order to achieve high accuracy and speed at a minimal cost.

From the Standardization to the Internationalization of the Accounting Information

Boghean Cristina Iuliana
University of Craiova, Faculty of Economics
cristinaboghean@yahoo.com

Abstract

Accounting standardization represents a uniform system of rules designed for a range of economic entities located in a particular geopolitical location or in a given geographical area.

Accounting standardization aims to achieve the following objectives resulting from the characteristics of the modern world economy, namely: the vital need for information and communication, the universality of classifications for real and cash flows; the widespread of the electronic treatment of information and data. Nowadays, accounting standardization exists in most countries.

Romania wants to match its legislation on accounting issues with the EU Directives and to take into account the emerging trends in international standardization. The decision to implement IFRS in Romania involves dealing with the need for new interfaces with the European Union, its regulatory accounting bodies, as well as the national accounting standards setting bodies in the Member States.

Key words: accounting standardization, information, accounting

J.E.L. classification: M41

The concept of standardization in accounting arose due to the need of harmonization and uniformity in accounting in most countries.

Accounting standardization stands for a uniform set of rules designed for a commercial or nonprofit entity located in a particular geopolitical location or for a group of entities located in a specific geographic area, regardless their ownership or field of activity.

Accounting standardization requires creating accounting rules or provisions; these are improved as to give a common denominator concerning the mode of action and application in order to achieve comparability and interpretation of the accounting information content. After fulfilling these conditions, these accounting rules or provisions should be globally applied by internationalizing them. Internationalization of accounting has its source in the international convergence and harmonization of the principles, bases, rules, conventions and specific accounting practices.

Accounting standardization aims to achieve the following objectives resulting from the characteristics of the modern world economy, namely: the vital need for information and communication, the universality of classifications for real and cash flows; the widespread of the electronic treatment of information and data.

Nowadays, the international body that focuses its activity in completing this complex process is the *International Accounting Standard Board - IASB*, an organization specialized mainly in developing rules for stock exchange and multinational companies. This body is considered a promoter of international accounting standardization, but like any neutral body, it has not been exempt from criticism and contradictory evidence related to the allocation of actions, mainly relating to:

- (a) actions of accounting standardization and harmonization made by the European Union;
- (b) the application of the Anglo-Saxon accounting rules in countries where accounting has a continental character or other influences.

Thus, harmonization of international accounting conducted by the accounting body is a necessity imposed by the requirements belonging to users of financial statements. The determining factors in this process are listed below:

- globalization, globalization of economies and capital markets, which provides the accounting rules an international character;
- creation of regional power centers, by extending the borders of the European Union (EU), which leads to the rise of international capital movement process;
- diversification of globally competitive methods;
- design of a standardized accounting system and generally able to determine the efficient operation of business activities;
- creation of an optimal convergence between internal and external system in terms of financial information.

These phenomena, taken individually as well as based on the interdependencies that are created between them, link to the creation of aspects belonging to the *accounting marketing*, namely the *market of accounting information*.

Achieving these objectives will result in the creation of accounting rules, capable of providing financial information useful in the process of the users' making decisions; these users will act based on their information background. The process of creating accounting rules has generated in time *two directions*:

- *the conceptual or deductive direction*, in which the accounting concepts and principles are determined by professional reasoning, these being based on the methods and procedures applied in practice;
- *the pragmatic or inductive direction*, in which the accounting concepts and principles are determined based on experiences and traditions.

These directions have led to the creation of two major world accounting systems, namely the *continental accounting system* (the *conceptual direction*) and the *Anglo - Saxon accounting system* (the *pragmatic direction*).

In Romania, the accounting standardization is performed by the State and the institution regulating the accounting standardization is identified with the Ministry of Public Finances, *Accounting Regulatory Directive monitored and supervised by the Financial Reporting Council of the Ministry of Public Finances*.

The issue of the accounting standardization arose due to the need of standardize accounting practices used by various professionals in order to allow publishing information for a proper understanding and appropriate grounds of comparison.

The whole expression of the standardized accounting is the result of a set in which different elements are linked by a common structure.

Even if there are many doctrinal changes, in most countries the accounting standardization is an obvious and up-to-date process. The accounting standardization has as object and purpose the application of "accounting rules identical in the same geopolitical space and aims to create uniform accounting practices." [3] Nonetheless, a global type of standardization is currently utopian, but not perpetual.

Regardless the private or public nature, the accounting standardization process will finally manage:

- to create an "accounting dictionary" appropriate for all users of accounting;
- to define coherent principles generally accepted;
- to identify information contained in financial statements that are made public;
- to give a method of presentation for financial statements;
- to develop a plan of accounting and operating rules with view to the registration of various categories of operations.

If for small geopolitical areas (region, country), this is relatively easy to put into practice, for "large areas", the accounting standardization faces clear problems:

- The existence of a multitude of issues that cannot be standardized as the accounting rules take into account the specificity of a concrete problem and its particularities;

- The "stiffness" of the professional accountant trapped in obsolete rules as his rational creativity based on the utility aspect of the product (information) he offers to the public will be eventually affected.[1]

Nowadays, accounting standardization exists in most countries. Each of them has its own terminology and rules that lead to an identical presentation of financial statements for all companies. The technical interest is obvious: the uniformity of the provided information facilitates comparisons over time and across companies and also allows the national accounting to achieve macroeconomic aggregates. On the other hand, standardization guarantees to third party users coherence and rigor, indispensable qualities for a responsibly held accounting. Terminology, classification rules, and in general, everything related to the order of accounts are subject to accounting standardization.

Business development and globalization have generated an increase in mergers and acquisitions, which led, inevitably, to the increase of the financing needs, hence the most recent developments in international capital markets. This growing international dimension revealed that the accounting information is one of the most essentials means of communication.

Romania wants to match its legislation on accounting issues with the EU Directives and to take into account the emerging trends in international standardization.

The decision to implement *IFRS* in Romania involves dealing with the need for new interfaces with the *European Union*, with its *regulatory accounting bodies* (*General Directorate – Internal Market; Accounting Regulatory Committee – ARC*), the *European Financial Reporting Group (EFRAG)*, as well as the national accounting standards setting bodies in the Member States. Also, there is the requirement to align national accounting activities with those of IASB's and its committee; in addition to this, any information or guidance on the application of IFRS should refer to IASB's General Framework and to the principles which are ground for each and one IFRS.

Based on the duties of such specialized bodies at the level of the EU and its member countries, the major problems that fall under the responsibility of this group (the Romanian Accounting Group - GRC), are mainly the following ones:

- to provide a permanent structure and a unique source of technical expertise in the application of IFRS in Romania;
- to study the new standards issued by IASB, IFRIC interpretations and to provide necessary guidance to users in Romania, where appropriate;
- to ensure that all IFRS and interpretations associated with the corresponding regulations are effectively in force under the law and that there is cohesion with the accounting regulations applicable to the other entities;
- to ensure the management and control of the IFRS translation process and other relevant materials, consequently to their adoption in Romania;
- to work with IASB and the specialized accounting bodies from the European Union, the Ministry of Finances in Romania and professional bodies on all matters of interest relating to IFRS.

Adopting IFRS represents a new system of procedures to be implemented at the level of an entire organization. The new accounting points of view aim at fully implementing accounting standards that have not been used in Romania, as well as the application of IFRS standards.

Abstract

C&D&I, part of the priority of economic growth based on knowledge and innovation is one of the key actions of the Lisbon Agenda. According to guidelines set by the Lisbon Strategy, according to European Union policies, science and technology are the real key instruments for the European future. The essential role of scientific research and technological development to increase economic competitiveness has been stated repeatedly by the European Commission, i.e. developing a knowledge-based economy.

Key words: competitive advantage, regional innovation, internal innovation, Innovation from external sources

J.E.L. classification: O

1. Introduction

Goals and Objectives of the Lisbon Strategy for Research, Development and Information Society are:

- Total expenditure for R & D to reach 3% of GDP by 2010 (1% spending supported by government expenditure and 2% held by companies);
- Business expenditure for R & D to reach 67% of total spending by 2010;
- Housing connected to the Internet to reach 30%;
- Governments to provide 100% online by 2010.

Comparative analysis of the most commonly used indicators show a trend of increasing development of information society in Romania.

Review of the Lisbon Agenda in March 2005, has changed the strategic thinking vision for the economy and society at EU level, moving the emphasis on economic growth based on technological progress and employment. One of the three major objectives of the new agenda is to promote economic growth based on knowledge and innovation.

To become a competitive advantage in the Region, innovation must overcome stage isolated actions, the personal initiatives - it must become a mass phenomenon, characterizing the approach that most SMEs in our priority sectors.

2. Activities and innovation needs of firms in the region

The innovation needs analysis, it appears a more unfavorable factors influencing regional innovation. Despite economic progress and rising trend, the access of SMEs, but also companies, research and development is limited. Almost half of respondent companies have assessed high financial costs as one of the main obstacles to the development of internal innovation - this in a context where more than one third (35.4%) did not have sufficient resources to finance their own entire portfolio development projects and only 42% submitted before the introduction of innovation projects for grants and auction programs (Phare, SAPARD, the Framework Programme, etc.).

High share of small and medium enterprises could mean a modern production base, ready for innovation. The more so as, in time there is an increasing trend towards micro-enterprises in the region, which can be attributed to their market success. In the

Northwest Region is required to start a broad process of consultation, discussion and information on innovation as a strategy not only regional but also at sectorial and company level. To become the region's competitive advantage, innovation must overcome stage isolated actions, the personal initiatives - it must become a mass phenomenon, characterizing the approach that most SMEs in priority sectors. For this, we need to implement a regional system support, providing all the tools they need in the region for companies to innovate or to adopt innovations.

The system must support both:

- Internal innovation - generating new ideas and internal experts to develop and implement their organization after the internal work (where process innovations, marketing and organizational) or sell them in the form of innovative products;
- Innovation from external sources - the organization adopt innovative ideas and practices from outside, they adapted to their needs and implement them in their current business or marketing in the form of innovative products.

Number of innovative companies is three to four times smaller firms as a share of total EU average. However, implementation of innovations began to be forever more an advantage for their companies in a competitive market and competitive, but the regional impact of different forms, the economic impact should be considered in conjunction with the objectives of innovation policy.

The data illustrates the priority orientation towards product innovation (especially in sectors such as furniture, tourism and machinery and equipment), followed by the innovation to the process (especially in agriculture, furniture and clothing). Organizational innovation is very important for tourism or clothing, while innovation is valued in tourism marketing, food and agriculture. Furniture production sector recorded the highest share of companies that consider innovation as their competitive advantage primarily present (27%), but followed closely by IT & C sector (24%).

Firms in the tourism sector expects an increase of machinery and equipment of the importance of innovation to market success

(76% and 69%), agriculture, food processing and textiles and clothing sectors remain the share of companies applying little or no innovation is highest - cumulative percentage, 55% in agriculture, 38% and 28% in food, clothing and textiles. In the exploitation of staff, employees, statistical investigation of surprised there are widespread problems in all priority sectors, namely the difficulty of finding technical personnel capable of generating innovative ideas (greater percentage of 50% for clothing and furniture). Almost a third of firms surveyed in the region believe that human resource is not well prepared by the education system and lacks the knowledge and skills needed to support the innovation process.

On the other hand, some sectors such as furniture production, agriculture or tourism, small businesses have a reduced financial strength, focused on serving local markets, without investing in particular technology. In other sectors such as garments and textiles, the existing small and medium businesses have operated mostly in the system, a system in which technologies, models and production process were taken as standard from the outside. In such cases, a high proportion of small and medium rather difficult technical progress and innovation.

In terms of regional specialization by industry sectors found to be agriculture, food and clothing and textiles are industries whose development would lead to positive developments throughout the region. On the other hand, the strategy should stimulate the development of natural clusters in certain industries and whose bleeding can bring significant benefits for the local economy of their area of location, but also increase the competitiveness of SMEs, to support joint research, to rationalize costs and to implement all types of management.

In some sectors of the region, policy improvement simply cannot ensure long-term competitive advantages.

Clothing sector, for example, cannot be based solely on his status as a traditional producer loan. Faced with increasing labor costs, energy costs, the increasing shortage of qualified personnel and fierce competition from multinational companies or manufacturers in Asia, companies need not only radical changes in products, but their

strategies business. One example is the need to create strong brands, brand new challenge for many companies in the industry, involving a number of major decisions:

- Investments in specific policy means of communication (e.g. advertising or PR);
- Orientation to new categories of products, quality, or the luxury segment for specialized products for niche markets - counteracting thus prices lower than average quality of goods imported from Asia;
- Extending the field of marketing through networking of stores in new malls and hypermarkets to be opened at a rate so high in the region.

Of course, such business strategies with a high risk and require openness to radical organizational innovation - which, just as focus groups have shown, is not the case for all companies in the sector.

Such decisions radical are needed in agricultural production - to cope with increased imports, the IT&C - to cope with the increasing shortage of workforce highly skilled or tourism - to find solutions to increase demand conditions an overstatement of supply.

Regarding the orientation of the regional economy in relation to global trends, the boom in the number of IT firms show a connection to the regional economy to new economy - one that uses information technology and communications infrastructure to increase flexibility, speed and interactivity between companies market and between companies and households. Connecting to the new economy but there is no uniform, clearly dominated the most developed counties, Cluj, Bihor, which is the largest concentration of firms in the ICT sector (70%), the largest geographic concentration of consulting firms and software in this sector is far from Cluj., while other branches of industry such as telecommunications, computer data processing, IT and other activities can be found in Maramures and Bihor.

Tabel 1. Indicators relating to the IT sector at regional level (NW Part) and national

-%-

Region	Share of enterprises with Internet connection in all enterprises in the region	Number of computers per employee	Number of PC share of total Internet connected PC in the region	Number of ITC specialists share to 100 employees
North West	8,2	8,8	48,4	1,7
Bucharest	12,2	13,6	60,1	2,5
Romania	8,5	9,7	48,9	1,7

Source: National Institute of Statistics, 2007

Defining an IT cluster possible, the best location would be the county of Cluj, where they existed for many years and also Transylvania cluster initiative (IT), which however could not be implemented and made because of lack of funds for creating and sustaining such structures, technical difficulties in creating partnerships between firms.

Another cluster can be identified from demand analysis in the furniture sector in view of the natural potential but the location of industry in the region's four counties (Bihor, Cluj, Bistriștrița-County), but because of the diversity of products makes it difficult to develop horizontal and vertical of these types of clusters. If we consider another priority sector machinery and equipment, we find that the greatest concentration is found in the county of Cluj in the newly established companies, along with those in the county of (60% of companies registered since 2001 in the same area of total) .

Another sector that would benefit from the networking and cooperation between companies and public entities is the tourism sector. Due to the diversity of actors who make up the value chain in tourism, cooperation and cluster activities is an effective approach to promote regional tourism as an economic activity.

Integration initiatives for tourist attractions, products, agencies, hotels and other services and initiatives of public authorities, national and European networks should be supported especially in three of the

six counties where tourism is a high importance, Cluj, Bihor Maramures.

Following surveys in the NW Region in terms of innovation activities, according to the Lisbon Strategy was found that positive things are just over 20% of businesses in the region feel the need for innovation not only in small measure, and over 30% of companies surveyed in the region have only marginal semnficative concerns in this area.

The graphics are highlighted in the results of surveys in the NW Region of regional innovation activity.

Chart no. 1. Survey results regarding the analysis of innovation by improving products / processes in the NW Region

Source: www.adr.ro, innovation needs analysis in the North-West

Perhaps this need is the fact that RDI funding in recent years the region has benefited from one of the lowest funding of public funds 4.80% -57.33% compared with Bucharest, Ilfov - 13, 92%, Central Region - 6.66% and the West - 6.80%.

This has a negative influence on competitiveness and performance of all sectors in the region.

In other news, not all actors in the region believes that innovation is essential in the production of competitive advantages and thus increase performance at the regional level.

Lack of proper understanding of the dimensions of innovation, inability to correctly perceive the magnitude of the changes required or mandatory character of improper management creates a culture of innovation generation in many of the leading firms in priority sectors in the Region.

Even a manager who understands the importance of innovation and transforms it into an organization-wide policy depends on

its employees to generate innovative ideas and development.

From this point of view, region-wide surveys were surprised that there is a widespread problem in the surveyed companies in priority sectors, as shown in chart no.2.

Chart no. 2. Survey results on the difficulty of finding technical personnel to enable the generation of innovative ideas

Source: www.adr.ro, innovation needs analysis in the North-West

Almost half the firms surveyed, the region complain of difficulty in finding technical personnel capable of generating innovative ideas (the percentage is greater than 50% for clothing and textiles or furniture production). Paradoxically, however, the same managers that "the absence of innovative ideas" is not a problem for firms in the region, and an even smaller percentage of respondents (5%) blames the lack of innovative ideas funds and European programs.

However at present, companies in the region have staff capable of generating innovative ideas, but finding such employee becomes a task increasingly difficult. Is a serious problem, especially because companies in the region also faces high turnover of staff. The fact that the Cluj-Napoca has become lately a magnet for large investments in many of the priority sectors (ICT, machinery and equipment, tourism, etc..) contribute to an increase in this trend - companies already on the market lose employees able, attracted by wages and greater opportunities for advancement offered by new entrants.

Companies offer training in the region, as a means of continuing education and training, is better appreciated, as shown in chart no.3.

Chart no.3. Survey results on inadequate training supply businesses in the region and how this influences innovative activity in the region

Source: www.adr.ro, innovation needs analysis in the North-West

3. Conclusions

Implementing a culture of innovation among staff across all sectors in the region can be achieved only in the context in which innovation concerns are adequately rewarded through a policy of reasons well set.

In the North-West Region found 10% of all actors with research development at the national level, public versus private institutions share being 33.83% 66.17% respectively public and private institutions. Of the total 133 CDI unit, the regional distribution of types of actors in the Northwest region indicates a majority of university stakeholders - 11% of all national universities, followed by research institutions, development, innovation and firms C&D&I.. At the regional level are found 10% of companies performing CDI activity, 9% of the research institutes of the Academy, 7% of research institutes organized in the case of autonomous national and 2% of total national research institutes.

Sales via the Internet (e-commerce) is still underdeveloped, both in the region and nationally (on average less than 2% of businesses selling over the Internet, and the percentage of those who buy through the Internet is similar).

In the region, the number of firms developing software products for foreign markets is growing with opportunities for diversification and development of its software products with high added value. (ERP, multi-media solutions in the field, quality management, e-learning, e-government, process innovation, etc.).

The potential of this sector for the Northwest Region is supported by the number of specialists who continuously creates by graduating university and technical faculties in the region.

A Novel Pseudo-random Bit Generator Based on Some Transcendental Chaotic Systems

Boriga Radu

Dăscălescu Ana Cristina

"Titu Maiorescu" University of Bucharest, Faculty of Economics

radu.boriga@utm.ro

cristina.dascalescu@utm.ro

Abstract

Chaotic maps have attracted great interest for its special use in secure communication systems. It is proved that for some chaotic maps defined by $x_{n+1} = f(x_n)$ we can find an analytical solution, so systems can lead to predictability. In this letter, we propose a new kind of chaotic map based on transcendental equations, which appear completely different deterministic random behavior with the known chaotic maps and have a kind of more complicated dynamical behavior. We study the effectiveness of the practical application of such systems for generating sequences of pseudorandom numbers and we investigate the properties of the obtained data to confirm them for cryptographic purpose.

Key words: chaotic systems, pseudo random, cryptography, stream cipher, transcendental equations

J.E.L. classification: C22

1. Introduction

Chaos-based cryptography (also known as chaotic cryptography) was born twenty years ago, but it was more developed in the last ten years, mainly due to the increasing needs for new methods for data encryption, required by fields like telecommunication, e-commerce and banking.

Chaotic cryptography it was and still it is a promising alternative for classic cryptography because many chaos fundamental characteristics such as a ergodicity and high sensitivity to initial conditions have a direct correspondent in two basic properties of good ciphers: confusion and diffusion.

Mainly, there are two ways to use chaotic dynamics in cryptography: the first one uses chaotic systems to generate pseudo-random number sequences, which are then used as keystreams to mask the plaintext, while the second method uses the plain text as initial state and the ciphertext follows the orbit of the chaotic system. The first method fits to stream ciphers, while the second fits to block ciphers.

A big disadvantage of chaotic cryptography comes from the fact that the authors of chaotic ciphers did not take care about security issues. Due to this fact, most of the proposed cryptosystems were shown later to be unsecure against one or other type of attack, while the safer ones were typically too slow to compete with classic ciphers. This shortcoming of chaotic cryptography it's mandatory to be removed so as chaotic cryptography to be considered a viable alternative to the classic cryptography. In the next chapter we will briefly introduce some chaotic maps used in cryptography, together with a brief analysis of their specific properties.

2. Solvable chaotic recurrences

The most used map within the studies on dynamic and chaos systems is the logistic map, described by the recurrence:

$$x(n+1) = f_L(x(n)), \quad (1)$$

where $f_L: [0,1] \rightarrow [0,1]$ is defined through:

$$f_L(x) = rx(1-x), \forall x \in [0,1] \quad (2)$$

The behavior in time, of the logistic map, depends on the value of the parameter r as well as the starting point represented by the initial condition. In figures 1, 2 and 3 we have summarized the complete dynamical behavior of the logistic map using the bifurcation diagram, exponent Lyapunov and distribution probability of the logistic map trajectories.

Figure 1. Bifurcation diagram of the logistic map

Figure 2. Lyapunov exponent of the logistic map

Analyzing the bifurcation diagram and exponent Lyapunov, it can be observed that for values of the parameter r between the interval $(3.57, 4]$, the logistic map has a chaotic behavior. The distribution probability of the logistic maps trajectories is showed in figure 3.

Figure 3. The distribution probability of the logistic map

It has been shown analytically that for the logistic map with system parameter $r = 4$, the probability distribution is given by [1]:

$$\varphi_f = \frac{1}{\pi \sqrt{x(1-x)}} \quad (3)$$

Another category of maps preferred for the simplicity and performances given in cryptographic applications, is represented by the tent map:

$f_T(x): [0,1] \rightarrow [0,1]$, defined through relation:

$$f_T = \begin{cases} \frac{x}{p}, & 0 \leq x \leq p \\ \frac{1-x}{1-p}, & p < x \leq 1 \end{cases} \quad (4)$$

where p is the parameter of the tent map. It is a non-invertible transformation of unit interval into itself and contains only one system parameter p , which determines the position of the tent in the interval $[0,1]$.

Recently, it has been demonstrated that different chaotic recurrences as $x_{n+1} = f(x_n)$ have exact solutions written explicitly under the form [3]:

$$x_n = P(\theta T z^n) \quad (5)$$

where $P(T)$ is a periodical map, z is a whole number, θ defines the initial condition $x_0 = P(\theta T)$, and T is the period of the function $P(t)$. A particular case of the relation (5) is

$$x_n = \sin^2(2^n \arcsin(\sqrt{x_0})) \quad (6)$$

which is general solution of the logistic map $x_n = 4x_n(1 - x_n)$. Similarly, the tent map defined by the relation (4) has the analytic solution:

$$x_n = \frac{1}{\pi} \arccos(\cos(2^n \pi x_0)) \quad (7)$$

The exact solutions of the chaotic dynamic systems allow the rise of the accuracy and computing speed. Instead of iterating a function, it can be calculated a value of a term using the analytical expression of the solution, avoiding in this way the numerical errors which can appear during iterations. Also, this procedure allows the direct calculation of the value x_k , avoiding $k-1$ iterations of the system.

The disadvantage of these number generators is given by the system's predictability. A remedy for this

disadvantage is to use chaotic dynamic systems with no solutions by Gonzales and Pino. As is well known that transcendent equations have no analytical solutions, it seems that they are good candidates for constructing unpredictable cryptographic systems.

Thus, for the construction of a pseudorandom number generator we'll propose two maps, one of them being one-dimensional map and another bi-dimensional map. The analysis of the proposed maps is presented in the next chapter.

3. The analysis of the proposed maps

For the construction of a pseudorandom number generator we'll propose two new maps, one being one-dimensional and one being bi-dimensional, both of them with a single parameter. In the beginning it is analyzed the one-dimensional map defined by the relation:

$$x(n+1) = f_1(x(n))$$

where $f_1: [-\frac{\pi}{2}, \frac{\pi}{2}] \rightarrow [-\frac{\pi}{2}, \frac{\pi}{2}]$ is given by:

$$f_1(x) = \arcsin(\cos(x + e^{r(1+x^2)})) \quad (8)$$

and r is the parameter of f_1 .

The behavior of the map f_N in time depends on the value of parameter r , as well as on the starting point represented by the initial condition. The bifurcation diagram is presented in figure 4.

Figure 4. Bifurcation diagram of f_1

At the value $r = 0.5$ the only attractor starts to split in two. After the value $r = 0.75$, the attractors split in four, eight, etc. Thus, for a value of a parameter r greater than 5, the map has a full chaotic behavior.

The conclusion is sustained also by the value of the Lyapunov exponent, represented in figure 5.

Figure 5. Lyapunov exponent of f_1

In figure 6, there are represented the distribution probabilities of the trajectories of the type (8) map which start from different initial conditions ($x_0 = -0.1$ and $x_0 = 0.9$), with the system's parameter $r = 10$. Here, the interval $[-\frac{\pi}{2}, \frac{\pi}{2}]$ has been split into 100 subintervals and for each trajectory a total of $N=10^6$ points has been used.

Figure 6. The distributions probabilities of f_1

It is obvious that the two distributions are identical. Therefore, the map keeps an invariant density for values of parameter $r \in [5, 10]$.

Now, we start to analyzed the bi-dimensional map defined by the relation:

$$\begin{aligned} x(n+1) &= f_2(y(n)) \\ y(n+1) &= f_2(x(n)) \end{aligned}$$

where $f_2: [-\frac{\pi}{2}, \frac{\pi}{2}] \rightarrow [-\frac{\pi}{2}, \frac{\pi}{2}]$ is given by:

$$f_2(x) = \arctg(\text{ctg}(x + \sin(r^3 x))) \quad (9)$$

The behavior of the f_2 map in time depends by the value of the parameter r and by the starting point represented by the initial condition. The bifurcation diagram is presented in figure 7.

Figure 7. Bifurcation diagram of f_2

At a certain value of the parameter $r \in [0,0.75]$ the only attractor value depending by r starts to split. After the value $r = 0.75$, the two attractors split in four, eight etc. Thus, for a value of a parameter r greater than 4, the map has a chaotic behavior. The conclusion is sustained also by the value of Lyapunov exponent, represented in figure 8

Figure 8. Lyapunov exponent of f_2

Figure 9 represents the distribution probabilities of the trajectories of the type (9) maps which start from different initial conditions ($x_0 = -0.2$ and $x_0 = 1.1$), with the system's parameter $r = 14$.

Figure 9. The distributions probabilities of f_2

It is obvious that the two distributions are identical, therefore the map keeps an invariant density for values of the parameter $r \in [10,20]$.

Based on the results described above, the maps f_N si f_B defined by the relations (8) and (9) have a chaotic behavior for a big range of

values of the system's parameter and keeps an invariant density making this one to be successfully used in realizing strong pseudorandom number generators from the cryptographic point of view.

In the next chapter is presented the analysis of the statistical results for the pseudorandom number generators based on the proposed chaotic maps.

4. The analysis of randomness for keystreams generated using the proposed functions

The experimental testing of the randomness for keystreams generated using both of the new proposed function was performed using the automated system designed by authors and presented in [2]. The automated system is based on DIEHARD, a very well known battery for statistical testing of randomness of a PRNG, developed by George Marsaglia. For a certain input stream, DIEHARD performs more statistical tests to measure the quality of randomness of it and provides as output a set of 215 p -values. If a p -value, corresponding to a test, lies in the interval $[0.001, 0.995]$, we can conclude that the input stream passed that test. For our experimental analysis of randomness, we used, for each of the two proposed function, the same method for keystream generation, as it will be described below. For each new proposed function, we have generated 1000 keystreams and we plotted the obtained results as a histogram of total number of passed tests versus number of keystreams which realized that number.

The method used for generation of a keystream consisted in the writing of the real number $x(n+1) = f_1(x(n))$ or $x(n+1) = f_2(x(n))$ as an unsigned integer in the keystream. The obtained histograms are shown in the figures 9 and 10.

Figure 10. Histogram for f_1

Figure 11. Histogram for f_2

Analyzing the histograms of f_1 and f_2 , we can conclude that at least 99% from the generated keystreams, regardless of the function we used to generate them, have passed over 210 tests from a total of 215, in other words - over 97% of them. This entitles us to say that functiona f_1 and f_2 have a very good randomness.

5. Conclusions

In the third chapter we theoretically have demonstrated, using instruments of the theory of nonlinear dynamic systems, that the proposed map has a good chaotic behavior. From the analysis of the experimental results, presented in chapter 4, we can conclude that the randomness of the sequences obtained using the PRNGs based on transcendental maps, raises the level requested by the current standards for the construction of type string encryption keys, both for text and images.

Considerations Regarding the Reduction of Rural-Urban Disparities in the Developing North-East Region: Study on Iași Metropolitan Area

Borza Mioara
Tălmăciu Mihai

„Alexandru Ioan Cuza” University of Iași
Faculty of Economics and Business Administration

mioara@uaic.ro

mtalm@uaic.ro

Abstract

The developing regions creation represents a real challenge for the economic progress of EU countries. While some regions have an advantageous position in terms of future development conditions, there are others where are identified numerous impediments, on multiple levels. A detailed analysis of regional development possibilities requires a consideration of various and multiple criteria analysis.

In this paper we will refer to a development region from Romania, the North-East Region, which although holds a reach portfolio in terms of development conditions, is faced to many problems and obstacles. The main aspect that we identified as an obstacle for development of this region is the urban-rural disparities. The present study aimed to identify the main specific coordinates of rural sustainable development.

Key words: development, disparities, regions, rural, urban.

J.E.L. classification: R; R11

1. Introduction

The coordinates of rural development are anchored in a current issue for the national economy since it aims at attaining a stable balance between the need to preserve the rural values and the modernization trends. Sustainable human development may not be conceived outside the development of human localities, urban or rural, with a viable economy and a diversified social life (5).

Rural development is at the confluence between the expansion trend of the urban, industrial development and the need to maintain as much as possible the rural to its quantitative and qualitative dimensions. The scientific approach of the current issues of the Romanian rural area must take into account the fact that the development of villages may not be treated separately from that of the town. From the perspective of approach of the regional development which is the engine for the elimination of the rural-urban disparities, they measure certain key development indicators so as to identify the differences among regions, namely the differences between the villages and towns of a region. The significant analysed indicators are: GDP/inhabitant, unemployment rate, the number of SME's/inhabitant and the rural population. From the studies of statistic order made at national level, one may notice that both the regional disappearances and the urban-rural gaps from Romania have intensified and worsened (7).

2. Presentation of the developing North-East Region

The North-East Region is the largest of Romania having a surface of 36,850 km² representing 15.46% from the country's total surface. It is made of 6 counties. The population of 3,734,546 inhabitants, namely 17.25% from the Romanian population, is located in the rural environment (56.6%).

The first of the eight Romanian developing regions from the viewpoint of size, the North-East Region occupies the last place in our country in terms of the index of human development and the gross domestic

product/inhabitant, mainly due to the functional structure un-adapted to the market economy and an extremely low economic efficiency and productivity. From the perspective a social-economic analysis, the North-East Region is the most poorly developed at national level and occupies the penultimate place in Europe at the beginning of 2010 registering a GDP/inhabitant of 27% from the European average and 69.2% from the national average (8). The western part of the region has been in a process of deindustrialization for 10 years, a fact that worsened the economic situation, and the east of the region is traditionally underdeveloped.

There are areas having an advanced industrial decline and a high unemployment rate and they are mainly located in the areas surrounding the urban localities. The attractiveness index is the lowest in this region - 19.7 (by comparison, the highest level of attractiveness is registered by the North-West Region: 39.8).

The low attractiveness is directly observed by the reduced volume of foreign direct investments: 292 million Euros in 2005, only 1.3% from the total direct foreign investments in Romania.

Thus, besides the disparities of west-east development, in the North-East region we may highlight the rural-urban disparities in terms of the general development level, the infrastructure equipment of all types, and the level of attractiveness for investors.

3. Relevant aspects regarding the urban-rural disparities from the developing North-East Region.

Starting from the criteria defining the rural environment and the social-economic state of the developing North-East Region, in this case study we will present Iasi Metropolitan Area standing out by the need for development of its rural area. The basic observation is that the real development potential is not in a directly proportional ratio with the current stage of development of the area under study.

The idea from which we start in the social-economic analysis of the area under study is that, after a long period where the rural environment was the "victim" of the industrial explosion and rural exodus, they

started to reconsider the ratio between village and town in the developed countries, a period that may be called "rural reconstruction". Given the fact that today towns go through a new development stage where they extend towards the rural area and entail the adjacent areas in the increase processes making up social-spatial entities called *metropolitan areas* or *metropolitan regions*, we consider that it is normal that rural development of metropolitan nature should occur simultaneously with the development of rural areas taken over as a component part of a metropolitan area.

The analysis and research of the issues specific to the rural area is sustained by the following reasons: the rural area occupies the largest part of the territory of a country, the rural population has important shares in the developing countries and those in transition, the rural area offers opportunities for the carrying out of diverse economic activities (agriculture, tourism, food industry, handicrafts etc.), the rural area is the keeper of some unique cultural values and traditions.

The vision of the development process of Iasi Metropolitan Area comprises concepts and actions from different activity spheres and starts from the awareness of the need for development of Iasi in tight relationship with its neighbouring communes.

Iasi Metropolitan Area is a partnership variant where the common issues of Iasi and neighbouring communes may be solved, by which one may assume roles of national, regional and European level and turn to good use the chances for the area development so as to reduce the urban-rural disparities.

In April 2004, the County Council of Iasi, the Town Hall of Iasi and the town halls of 13 communes have become partners in planning and implementing the integrated development of the geographical and social-economic potential of Iasi Metropolitan Area (IMA).

As for the integration of Iasi Metropolitan Area into the developing North-east Region and the European Union, in Table 1 we give the comparative situation for a set of basic indicators.

*Table 1 Comparatives indicator:
IMA - Iasi County - North-East Region -
Romania - European Union*

Indicator	EU	Romania	N-E Reg.	Iasi County	IMA
Total area - km ²	4.230.000	238.390	36.850	5.476	808
Total Population (2007) – inhabitants	495.100.000	21.565.119	3.726.642	825.100	390.436
Density population (2007) inhabitants/km ²	.	.	101,10	148,4	483,21
Occupied population (2002)	.	.	1.308.900	302.800	150.997
Students number (2006/2007)	.	785.506	79.762	60.000	60.000

Source: data processing by information from <http://epp.eurostat.ec.europa.eu>; www.insse.ro

The data from Table 1 show that Iasi Metropolitan Area occupies 0.019% from the EU surface and 14.75% from the surface of Iasi County, so it does not occupy a very large territorial area. From the viewpoint of population, IMA has 0.07% from the EU population and 47.31% from the population of Iasi County (almost a half). The share of employed population in the total population of IMA is 38.7% as compared to the average of Iasi County which is 36.7%. As for the number of students, the existence of university centres in IMA represents an advantage since 75.22% of the students from the North-East region study in Iasi.

As for the sustainable use of the natural and social-economic potential of Iasi Metropolitan Area, the main advantages for the elimination of the urban-rural disparities are: the flexible economic basis of a high technologic level, equipment level ensured by institutions of political, legal and economic decision of international, national and regional importance and by educational, scientific research, health, cultural, commercial, mass-media, public order units, etc.

In tables 2, 3 and 4, we present some data referring to the level of economic activities carried out in Iasi Metropolitan Area (from 2007 year) and they are presented in the light of two reference indicators: turnover and the distribution of the number of companies by fields of activity. At the same time, the data from Table 5 highlight the extremely high level of rural-urban disparities from Iasi Metropolitan Area in terms of the number of enterprises possessed by every area.

Table 2 The turnover distribution of active enterprises by activities domains in IMA

Commerce and tourism	43,81%
Industries	22,17%
Constructions	15,44%
Services	13,94%
Research, development and high-tech	3,64%
Agriculture, fishing and aquaculture	1%

Source: data processing by information from http://www.zmi.ro/analiza_economica_zmi.html

Table 3 The number of actives enterprises distribution by activity domains in IMA

Commerce and tourism	43,64%
Services	31,60%
Industries	10,15%
Constructions	8,3%
Research, development and high-tech	5,15%
Agriculture, fishing and aquaculture	1,15%

Source: data processing by information from http://www.zmi.ro/analiza_economica_zmi.html

Table 4 Existing enterprises in IMA

	Large enterprises		SME's	
	Number units	%	Number units	%
Urban	44	97,77	18.778	91,64
Rural	1	2,23	1712	8,36
Total	45	100	20490	100

Source: data processed by document entitled *Integrated Development Plan 2009-2015 for IMA*, viewed at <http://www.zmi.ro/downloads/PIDPC%20IASI%201.pdf>

From the data given in Tables 2, 3 and 4 one may draw the following conclusions obtained by comparison with the information related to the potential of rural development

of the communes from Iasi Metropolitan Area previously presented:

- the sector where most companies act (43.64%) and which has the highest turnover (43.81%) is that of commerce and tourism; we consider that the contribution of this sector is remarkable and that future investments should be guided more towards tourism exploitation, given the existing potential;
- industry, though occupies the second place in terms of contribution to turnover (22.17%) and the third place in terms of the number of existing companies (10.15%), does not fully reflect the possibilities of turning to good use the existing resources;
- constructions are poorly represented in terms of the contribution to the social-economic development, the number of companies acting on the market of IMA being extremely reduced (8.3%), and turnover is only 15.44%; so, this sector also needs a reorientation of thinking from the viewpoint of the development perspectives;
- services occupy a quite satisfying position in terms of the existing companies (31.60%), but the contribution of turnover is low (13.94%); from the interpretation of these values we observed that the qualitative contribution of the provisions of the service companies is not satisfactory and that there are necessary new strategies for the reversal of the dynamics of services from IMA;
- as for the fields of research-development and high-tech, the data do not offer a satisfying conclusion; whereas IMA is recognized as a prestigious university and research center, we consider that the number of units acting in this domain is extremely low (5.15%) and the contribution of turnover is almost insignificant (3.64%);
- the most unfavourable solution may be found in the domain that should highly contribute to the rural development of Iasi neighbouring communes, namely the agriculture, aquaculture and fishing that contribute with only 1% to the turnover afferent to the metropolitan area and only 1.15% from all companies work in this sector; for these reasons, we express our critical opinion according to which the

development of a rural area without a healthy, dynamic and viable agriculture is not possible;

- the difference/discrepancy between the number of large, medium and small enterprises existing in Iasi as compared to all 13 communes from the metropolitan area is more than obvious and suggestive so as to establish some rapid and radical measures for the creation and sustaining of the development chances of the business environment in the rural area, too.

4. Strategic objectives for the development of I.M.A.

In accordance with the strategic objectives for the development of Iasi Metropolitan Area regarding both the municipality and the adjacent communes and related to the economic growth, rehabilitation/creation of the communication infrastructure, the improvement of the social situation, the turning to good use of the natural and cultural patrimony, the protection and preservation of the environmental factors and the promotion of territorial cooperation, they have proposed and launched investment projects in the rural area of Iasi Metropolitan Area. These refer to various domains of interest unanimously oriented towards the development of the adjacent rural areas of Iasi and are materialized in: arrangement of recreation areas, building family dwelling facilities, arrangement of wholesale and retail agro-alimentary markets, arrangement of wool processing workshops, opening a cheese making factory, creation of vegetable farms and vegetable product processing factory, reversal of industrial areas, creation of areas for production, commercial and service spaces.

The fulfilment of the investment objectives enumerated above may contribute to the diversification of the rural economy from IMA, the diversification and multiplication of the income sources for the inhabitants from the communes and thus allow the attenuation of the rural/urban disparities.

The development projects of Iasi Metropolitan Area include the economic and social sphere so that the urban-rural disparities should be diminished and the

inhabitants of the rural area included in the metropolitan area should enjoy the same life conditions and the same development rhythm in the social and economic plan as the inhabitants of Iasi who, at their turn, benefit from the privileges offered by the natural landscape and geographic potential of development of the rural area adjacent to the municipality.

5. Conclusions

Looking at the whole North-East region, we may notice discrepancies in terms of level and development potential between the more developed western part of the region and the lagged behind eastern part (especially Botoşani and Vaslui counties). The chance of the eastern areas neighbouring the eastern border of the European Union is to develop as a transit area for the products coming from the countries of the former USSR. For this, it is necessary to effectuate infrastructure works for the creation of some areas with specific facilities.

Due to the favourable conditions it has, the beauty of locations, the air and water quality and other natural resources, the mountainous areas and the inestimable cultural and religious patrimony, the North-East Region has a relatively high tourism potential that may be compared to other famous tourist areas from the country and abroad.

A traditional economic domain of the region, the wood processing industry has registered a significant progress in recent years in terms of the number of jobs and turnover. The increase of the furniture industry share in the total turnover shows an orientation towards the superior turning to good use of wood. At the same time, the textile industry has registered a spectacular increase of turnover in 2004 but productivity is low due to the use of Lohn system which has a small added value.

Among the general problems, the most important in Iasi Metropolitan Area is the need to improve the transport infrastructure so as to develop connectivity and the accessibility and mobility between the urban and rural areas.

The problems of the rural area are multiple and complex and favour the accentuation of discrepancies as compared to the urban area and of disparities as compared to the rural

area from many advanced countries of the EU. Among the problems directly related to the rural area we may mention:

- the deficiency of the technical-utility system and endowment with some basic utilities (water, sewerage, gas).
- the weak development of the road network and the low level of modernization of the existing transport infrastructure
- the lack of some landfills in most communes what represents a real threat to the environment quality;
- large surfaces of land abandoned, unused or insufficiently used;
- the lack of modernization of agriculture corroborated with the lack of professional forms of association lead to an inadequate subsistence agriculture;
- the structure of the poorly diversified economy negatively reflects on the use of manpower in the rural area, the quality of jobs and the income level of the inhabitants from the rural area.

The main territorial disparities registered in Iasi Metropolitan Area, mainly between the urban and rural areas, are:

- the high density of population in the municipality as compared to the low one in the rural area;
- the large disproportion between the population share in Iasi for the entire IMA and the share of population from communes in the entire IMA;
- the non-uniform distribution of the rural locality network in the territory;
- the poor diversification of the functional typology of rural settlements most of them having predominantly agricultural functions;
- huge discrepancies in terms of the very low level of income from the rural area and the higher level from the urban area;
- the poor development of the technical-utility facilities and the public utility services in the rural area.

Based on the results of the social-economic analysis, we propose the following measures:

1. Support and promotion of the SME's by specific activities;
2. Stimulation of SME creation in the production and service spheres;
3. Business information networks;

4. Development of the industrial activities concomitantly with the reduction of their negative effect on environment;
5. Fulfilment of the household and industrial waste management programme with an accent on the reuse of products and materials;
6. Rehabilitation of the areas affected by natural calamities;
7. Reconstruction of the natural capital in the deteriorated areas.

To attain these sustainability objectives in the rural areas adjacent to the big well developed towns or those having real development perspectives, it is necessary to implement measures such as: setting up some adequate entities for local governing, ensuring the adequate legal framework for the good development of their activities, promotion of the local economic development, creating a social and environmental sustainability, creation, development and modernization of the rural infrastructure, ensuring educational services that may guarantee the professional training and specialization of the rural population, ensuring the material, financial and human resources necessary for the application of rural development programmes and plans.

Thus, in Iasi Metropolitan Area it is necessary to attain some general objectives that may guarantee: the increase of competitiveness of the adjacent rural areas so as to maximize their contribution to the economic development, ensuring some opportunities for the rural population so that it may benefit from a life standard comparable to the urban norms, preservation and protection of the environment and the cultural inheritance existing in the rural areas, diversification and promotion of the occupational opportunities.

Analysis of Fiscal Decentralization in the Context of Modern Governance

Bosie Irina

"Alexandru Ioan Cuza" University of Iași,
Faculty of Economics and Business Administration
irina.bosie@uaic.ro

Abstract

Financial decentralization aimed the central and local state structure by increasing local autonomy, leaving available to local authorities, public finances. It extended a global phenomenon and the world's developed countries have implemented the concept. Developing countries continue to seek solutions for the application of forms of decentralization. Theories on the impact of fiscal decentralization have been thoroughly discussed by Tiebout, Hayek, Musgrave, Oates. Thus, were highlighted the importance and necessity of fiscal decentralization, the allocation of financial resources to local authorities, giving them extra financial power, tipping the balance to the competition between local authorities, which can determine the size of fees and taxes, the level of public expenditure growth decision-making power.

The concept of decentralization has been approached from different perspectives overtime and this article will highlight the importance of research on this branch by reviewing the literature.

Key words: decentralization, public services, efficiency

J.E.L classification: G20

1. Introduction

In European Union countries the decentralization implementing process took place relatively quickly, in most former socialist countries this process is still slow. By applying effective strategies and regulatory reform at the legislative level of decentralization can provide the increasing of

local autonomy. It relates to the increase in financial and economic quantity resources through more efficient distribution of financial resources by the absorption of structural funds and increasing the quality of public services in Romania.

We are witnessing the implementation of the concept of Public Private Partnerships for achieving financial objectives and performance of public services. Also, they have initiated projects for administrative capacity development, association on a regional level, projects orchestrated by the World Bank.

Over time the purpose of the associative cooperation and the role that state institutions are in the process of modernization has been a subject of controversial debate. In the study, History of Liberalism in Europe, (Nemo, 2006) it's described in the chapter entitled, Friedrich Hayek and liberalism genius, the Hayek theory of liberalism. Friedrich A. Hayek views the state intervention as a negative element that prevents the development of private initiative, undermining economic efficiency. Hayek argued that the state can not provide all public services, but some, such as public order and national defense. The degree of state involvement in public services is not considered as important as the appearance of non-involvement in private state in economic activities that can bring profit to the entrepreneurs.(Vrabie,2004)

It not called for the abolition of all state aid, but private sector involvement in state activities, namely the fulfillment of public services.

2. Theoretical contribution made by Oates and Tiebout

In his article, "The Use of knowledge in Society" perspective on the use of information obtained from public opinion, determine the acceptance of decision making closer to the citizen. Richard Musgrave develops a theory of public finance study that identifies three main functions: resource allocation, income distribution and economic stability. In its conception, the central and local governments designed to identify sources and destinations of money. He also stressed the necessity of government intervention on the collection and redistribution of public money.

Professor Wallace Oates has made great scientific contributions of the University of Maryland in the United States of America.

He developed a number of theories about local taxes, federalism and a theorem which was subsequently called optimal decentralization theorem. This theorem developed in his work on fiscal federalism has been the starting point in the decision of several countries, regarding administrative reforms, and contain elements which emphasize decentralization.

According to this theorem, Oates states that for a public good whose consumption area spans several geographic areas (local authorities), whose production cost is the same at both central and local level, will always be easily (or at least as easy) as that object to be produced in quantities in paretian meaning, optimal effect locally than centrally (or just like the central level). The theorem focuses only on the economic aspect of decentralization.

Wallace Oates supported the notion of "asymmetric tax transfer"(Garcia-Milla, 2005). This grouping of terms explains the existence of different tax arrangements between the Government and local administrations.

In Oates's perspective, but also from other scientists point of view, that have included in their studies the decentralization process, such as Charles Mills Tiebout, in the paper about the economic theory of fiscal decentralization, it was concluded that a decentralized system is more effective in identifying and solving problems faced by local authorities.(Tiebout, 1961)

To cover these needs effectively requires the development of a decentralized financial system, with local implications.

Oates took Tiebout's ideas and used them as a starting point in developing his theory on an optimal model of decentralization. He identified that as the exchange between the general requirements of the population on public services and would be the government response to these requirements.(Musgrave, 1959)

Local governments that have an amount of financial resources enjoy greater financial autonomy and respond more effectively to meet the needs of public services. In Oates's view, the authorities should be concerned with stabilizing the local economy. It encourages extrapolation services, which involves encouraging public spending.

Through this theory he is encouraging mobility, although the mobility made by citizens, by restoring the home, involves relatively large expenditures. They tend to embrace the idea of moving to another region to lead a quality lifestyle, but are prompted by financial reasons, in terms of taxes. Oates and Tiebout support the idea that, in terms of ensuring public services, a centralized government is much less efficient than a decentralized government.

This theory may induce the idea that the Central Government is considered ineffective, because it would be pointless. Why is the government getting involved when the regions do not have sufficient resources to meet their expenses? It gives tax breaks, subsidies. Researchers argue that decentralization encourages positive incentives. The idea that emerges from this statement is addressing to the development of the state when it is much closer to the citizen.

3. Public services, effects of decentralization

The public sector has engaged in a long process of profound change, to face new challenges. After more than twenty years of administrative reform and modernization initiatives in member countries of the Organization for Economic Cooperation and Development (OECD), the transformations suffered by the government have been significant. However, the transformation of the public sector is far from finished.

Government is subject to changes both locally and globally by business and civil society. Indeed modernization, economic growth and transformation and social movements in interacting with the media are challenges for governments and corporations worldwide.

Public domain is being reconstituted, both nationally and internationally, as a result of the new role of NGOs and the adoption of Corporate Social Responsibility Policy (CSR) by medium and large enterprises. Furthermore, we are witnessing the increasing number of public private partnerships. This process generates new state tasks in democratic societies. Increase its capabilities in this century and therefore the importance of institutions and organizations that lead to the implementation of partnerships.

The most significant innovations have occurred in public management reform and modernization initiatives in the last two decades, along with the growing body of literature in terms of public governance. The premise from which we started to use the concept of relational state is accepting that the state has ceased to be omnipotent and self-sufficient, modern state is considered to be a modest state, characterized by Crozier, which recognizes the complexity and interdependence inherent in many sectors and recognizes that social problems can be solved only through nomination and active involvement of society we live in.

The transition from traditional government to government quality-oriented, serving the common good of citizens, involves the adoption of strategies, policies and local development programs, technical assistance and appropriate training, effective coordination, control, monitoring and promotion strategies work. Studies have demonstrate that strategies promoting the concepts, are viewed as a fundamental criterion in the development of efficient public services. Each local authority will be to initiate dialogues with citizens, local organizations and private companies and to approve a particular project or partnership.

By conducting consultations and promote projects, local authorities will receive support from citizens and civic organizations, local businesses and will obtain the information

needed to formulate the best strategy. Strategies to shift from traditional government administration are supported and effective as a common denominator to obtain funding for local, national, regional and international to have the opportunity of making them.

Paul Drucker, in the paper about the efficiency of the decision-maker, believes that there can be no efficiency without effectiveness. Specifies that it is more important to realize better what you've suggested here, indicating the effectiveness, to achieve better than nothing-efficiency, noting that between the two terms are set to hand a report to the full and effective public services greatly influences efficiency.

4. Conclusions

Returning to the theories developed by scholars, we bring into question the fact that Tiebout said that fiscal decentralization has an effect on the efficiency of public services.

Studies in economics and geography have shown that in countries where taxes are set at regional level, the local party, the beneficiaries of public services, which are also paying taxes, they can choose how by transferring them to another administrative territorial unit.

Oates and Tiebout argued skewed idea of financial decentralization. This grouping of terms explains the existence of different financial arrangements between the Government and different regions.

Oates's perspective but also from other scientists who study included in their study of decentralization process, such as Charles Mills Tiebout (1924-1968), found that a decentralized system locally is more effective in identifying and solving problems facing local authorities. To cover these needs, it's very important to develop a strong financial decentralized system.

Arguments for decentralization are made from the perspective of population control that has on political issues and corruption. They can be easily found at the local level rather than the central and the reverse of this statement would be that the degree of manipulation and corruption in some cases would be much higher.

Decentralization of any kind brings more responsibility to the local authority. The tasks of those responsible may be hampered but will also need of experts and people willing to be trained in this area. Decentralization, if one can call it drastic, may not be possible.

The total financial independence from state authority is not possible. There are regions that can not collect local revenues so that they no longer need to receive state aid. Even with various forms by which sites attract FDI financing from EU funds, local government is weak and can not face alone to cover public expenditure.

Implementation of decentralization in Romania has known now slow, tortuous, never missed obstacles. Solutions were sought in order to streamline the implementation of decentralization, but authorities have been hit by shortage of funds, lack of funding, inefficient management, low quality public services and public money dissipating phenomenon unjustified manner.

To meet financial shortfalls at local government level, the European authorities resort to non-reimbursable European funds to supplement the financial resources needed to modernize local government, infrastructure and improving public services but also various "tricks" to obtain them through partnerships, local action groups, as miniature model of regionalization.

The Link Between Decentralization and Public Budgets

Bosie Irina

*"Alexandru Ioan Cuza" University of Iași,
Faculty of Economics and Business Administration
irina.bosie@uaic.ro*

Abstract

In an attempt to solve various problems that arise locally and improving public services, states in the transition period, have different strategies in terms of developing the financial systems.

The article highlights that the majority of states are in a situation where fiscal policy is determined by the Government and are applied according to instructions outlined in the territory. We are witnessing a decentralization achieved partly by the states.

Even if the premises are drawn, for the decentralization process, they are not strong enough to determine the implementation of fiscal decentralization to the regions. Dependence on state administrations on financial resources is obvious. The legal provisions on tax levies in some cases are regulated by local government. In some countries are drawn from the central level, but there are countries where the situation is mixed, decided by the central and local segments.

Key words: public budgets, decentralization, public administration.

J.E.L. classification: G28

1. Introduction

The public budget is the tool by which the state fulfills its functions: allocation, redistribution, macroeconomic stabilization and adjustment of economic activities.

The role of local budgets is to ensure local autonomy in financial terms, constituted on the basis of legal regulations that are sorted by the actual situation and to ensure local autonomy.

Making a link between the existence of financial autonomy and local public finance

we can define a system of economic relations. The system mobilizes and uses financial resources to local administrative units to meet collective requirements posed by education, culture, social welfare, public services and development.

Insufficient resources of local budgets have resulted in some of these additional actions. Thus England is the first country where the idea of Public Private Partnership established to facilitate the tasks of local governments, is the country where they developed the principles underlying the financial institutions.

The term spending in the public services, is a key factor to consider. The spending has grown exponentially over the years in Romania. Responsible in dealing with this trend of reducing public spending, but at the same time, meet the needs of the population, is the process of decentralization.

We can speculate that decentralization attracts more spending, but decentralization can argue that the authorities are aware of the needs of the local government, and the expenditures are increased due to the identified needs that were required to be covered.

These issues raise some important questions:

- Are the benefits to the population, through decentralized public services, exceeding expenditures in a budget of a local government, further than those specified in the original?
- Do we need to attract other funding sources to supplement the lack of budgetary funds?

2. Local budgets in Romania

Analyzing, Law 500 of 2002 on public finances, we can observe that a component of legislation that governs is the bookkeeping and financial resources.

Public financial resources are achieved through a uniform system of budgets that includes, according to Public Finance Law, the following components: the state budget, state social insurance budget, special funds budgets, the budget of the state treasury, budget-autonomous public institutions, budgets of public institutions funded wholly or partially from the state budget, state social insurance budget and special funds, as appropriate, public institutions budgets entirely financed from its own budget funds from external loans contracted or guaranteed by the state and whose refund interest and other costs are paid from public funds, external grants funding budget.

The consolidated budget has in its component financial flows, non-tax revenue and tax sharing their destinations in accordance with social needs and specific objectives of financial policy to which it relates.

Budgets are the main factor that determines the realization of state duties. The degree of accomplishment of public spending is influenced by the size of the budget. The budget provides local government autonomy. Through budgets are highlighted the resources to carry out the development of social protection.

State budget funds express economic relationships that occur during the distribution of national income opportunity fund formation and distribution of centralized, with general address to/and from the state to satisfy the interests of national problems. Effective financial decentralization has crucial role on the quality and level of local public services provided.

Distribution function of public finance is reflected in the budget, and results the financial decentralization. Distribution function takes place in two stages: first stage is to establish the funds and next stage is to distribute them.

Funds are established with the contribution of taxpayers that are represented by legal persons, individuals and the public institutions, public institutions subordinated units. The establishment of funds is done by collecting local taxes according to regulations.

Funds are collected to local government in form of: taxes, fees, fines, penalties, income from the sale of property belonging to the

private domain, income from concessions and rentals.

The funds are distributed in the second phase of the process according to local needs. These needs are recorded for education, social protection, culture, and various public services.

State or public sector entity is composed of all institutions at which decisions are collective or public administrations which are represented both at central and local government and public institutions.

The local budgets mobilize resources redistribution upon a series of economic tasks (infrastructure, extension and maintenance of water supply and sewerage, public lighting, transport, etc.). Direct funding from local budgets for these actions is ensured first by identifying the problems that occur locally. They are more easily identified by local governments in this way are removed some of the overly bureaucratized administrative steps. When local budgets expenditures are determined based on the established principle that no expenditure may be included in local government, can not be committed and done from the budget if there is no legal basis for that expense.

Local governments, in collaboration with school inspectorates, Health Departments, Department of Child Protection, County Departments of Roads and others, with the support of the General Directorate of Public Finance, shall establish each year the expenditure.

In this way, financial authorizing chief, secondary and tertiary officer determines spending requirements on standards and indicators. Foundation of public expenditure is carried out following the establishment of government spending.

At County Council level, decentralized expenditure have the following destinations: social assistance, child care, expenditure on special education resource centers and county educational assistance, cultural institutions decentralized, non-clerical employee contributions for members of religious establishments in the country, public services Community for People under the authority of county councils.

Law 273 of 29 June 2006 (Law 273/2006) on local public finances stipulates that the administrative-territorial units are entitled to sufficient financial resources, which local

authorities can use in their duties, on the basis and within the limitations prescribed by law. Local authorities have the power to establish the levels of local taxes under the law. By law, the amounts deducted from certain income to balance the state budget to local budgets will be distributed to counties, according to criteria established by law 273/2006. By law, county area is rated at 30%. Special-purpose deducted amounts shall be distributed according to law.

Financial capacity determined by the income tax collected per capita, the proportion of 70%.

In Article 33, paragraph 3 stated that the amounts deducted from certain income to balance the state budget to local budgets approved annually by the state budget law and the rate of 22% stipulated in art. 32. (1), a 27% share of the county's own budget is allocated, and the difference is allocated for local budgets of communes, towns and cities.

This is realized an allocating 80% of the amount allocated in two stages, according to population, area and financial capacity of the administrative-territorial. The remaining 20% of the amount shall be allocated by the County Council decision, intended for supporting local development programs, infrastructure generally requires local co-financing projects.

The amounts were not assigned in phase I are redistributed in phase II of the Territorial Administration of all units in the county according to their financial capacity, determined by the income tax collected per capita in the year preceding the year of calculation.

3. Cause-effect relationship

In a unitary state we can not rely on total decentralization, but rather on the decentralization of functions. Financial decentralization is seen as a measure to achieve good economic results. Testimonies to this statement were the United States, China, Britain, Spain, France, Italy and the list goes on. Transfers of responsibility from central to local, regional proved to be extremely effective.

Financial decentralization is a challenge for local government. Because of changes that have occurred in the transition from centralized to decentralized system was

necessary to establish new institutions and infrastructure. There was a problem with imposition reforms on privatization and decentralization of the economy, but directly, in decentralization of administration.

Romania, in the pre-accession period, published through the Government, for the period 2004-2008 a national strategy of decentralization that had the following objectives:

a) Reform of basic public services and public utilities of local interest;

b) Strengthening the administrative and fiscal decentralization;

c) Strengthening the institutional capacity of the central government and local;

Details of these dimensions of public administration reform were published in the Government Program, Chapter 11 entitled "Public administration reform".

Romania, in the decentralization process is slow. Significant changes have occurred in the year of 2009, by amending legislation in the areas of education, health, work. Also, identify major obstacles in implementing the decentralization process:

Lack of good legislation in place;

Lack of financial resources;

Lack of specialized personnel;

Excessive bureaucracy;

Financial Crisis.

After integration into the European Union in 2007, central authorities have tried to make a series of actions on the modernization of the administrative apparatus.

In this respect, the Government approved the strategy of decentralization in health, public safety, sports and youth, and in 2010 they have taken the law regulating education, culture, agriculture, the labor code.

Decisions made on the principle of subsidiarity, approaching the local authority's responsible citizens. It tends to have only the state control tasks.

The administrative reform strategy decision gives the mayor more power now than before and he will have dozens of new subordinated public institutions: schools, hospitals, airports, ports, agricultural directorates, labor, cinemas, and sports. Mayors will manage finances in the necessary proper course of these decentralized services.

4. Conclusions

Financial systems function as a set of institutions, processes and components linked by certain relationships. The link between the financial system with the economic and political is more than evident and one of the components can not function in isolation.

Local budgets revenue and expenditure administrative territorial units are independently developed, which stimulates local initiative to achieve revenue and meet local requirements.

According to the definition given by the Chamber of Commerce and Industry, self-financing capacity of companies is one indicator that reflects the company's financial potential to pay equity and to self-finance investment policy. From this definition we can implement the same requirements in terms of self-financing capacity of local authorities. This indicator determines the degree of financial autonomy of local authorities.

The degree of self-financing can be determined by the local authorities-own revenue share of total local budget revenues.

Analyzing the influence of local budgets in the process of fiscal decentralization, conclude that the share of expenditure showing planned to be performed, decentralized services local budget, determine the degree of financial decentralization. The degree of decentralization can be calculated and provided share of expenditures to be made for decentralized services and the state budget.

An Empirical Perspective on Acknowledging the Relationship between the Economic-Financial Communication and the Cost of Capital

Abstract

So far, numerous professional studies have focused on the effects derived from economic - financial communication (especially the voluntary one) on the capital market, all the while acknowledging the fact that the main consequences of this disclosure are essential for enhancing the liquidity of securities, for reducing the costs of capital and for encouraging, in any form, the secondary disclosure. Nevertheless, there are still certain grey areas that research is yet to unfold. Consequently, the authors of the present study wish to highlight a few elements correlated with the relationship disclosure-cost of capital.

Key words: communication, disclosure, value of economic capital, growth opportunities, financial-accounting reporting.

J.E.L. classification: M41,G10,

1. Introduction

Several approaches have been suggested by empirical studies focusing on the effects of financial reporting on the cost of capital. Among these, a first group of analysts have investigated the above mentioned association by using indirect measurements of the cost of capital, such as: risk indicators, purchase costs and informational asymmetries. A second group of researchers have focused on reporting decisions made towards the quoting on the capital market, while others have used direct estimations of the cost of capital.

The first studies have analyzed the relation between disclosure and the cost of capital by means of the impact of communication on the increased liquidity of securities as a result of an increased economic-financial voluntary communication and the decrease of informational asymmetries among informed and less informed investors, the latter being more confident that their shares would be negotiated at a fair rate. Moreover, there are studies focusing on the effects of the changes affecting communication policies, highlighting the importance of establishing the moment when these changes intervene, either by using analyst ratings or "disclosure" indices.

2. Debates

Most empirical findings have ascertained that communication decisions made by the company affect the speed at which the information is assimilated in the stock market prices. The increase of the reported information is actually associated with a simultaneous improvement in the evolution of securities after controlling the performance, the size and the risk, since the transmission of voluntary disclosure reduces informational asymmetries and limits the adverse selection phenomenon which, in its turn, leads to an inferior bid-ask-spread, i.e. the difference between a very high price that a buyer is willing to pay for shares and a very low price that a seller is willing to accept, other studies showing that a large quantity of information released on the market could increase the volatility of the securities and the cost of capital.

Other findings of the analyses that have recorded the "disclosure" effects on the "bid-ask-spread", as indicator of the liquidity of the shares, further confirm these effects, indirectly, even if on a segment disclosure level, based on the relationship between the reporting of additional data and the increased capitalization of the market, in agreement with the hypotheses related to the reduced cost of capital.

Further research has investigated the relationship between disclosure and the cost of capital, through the analysis of the managers' behaviour upon gaining access on the market, thus establishing whether they have acted appropriately in relation to a major reporting and to the cost of financing.

2.1. Basic concepts used when highlighting the relationship between communication and the value of economic capital

The value creation theory is usually linked to the value of economic capital, i.e. to an abstract market capital measure that meets the generality, rationality, demonstrability and objectivity criteria (Corvi, 2000, p. 21).

Under such circumstances, the economic capital value creation is a necessary objective of the company since it can meet the inherent objective of the entity – that of self-generation in time (Guatri and Vicari, 1994, p. 64).

The essential quantitative values that establish the value of economic capital may be expressed by the so-called key factors that establish the value. The following are especially taken into account (Guatri, 1991, pp. 49-59):

- The present value of economic capital (W)
- The value of growth opportunities of the economic capital (ΔW)

Growth opportunities are themselves established by the strategies and objectives that the company can achieve and this endeavour also depends on the environment circumstances and furthermore on the tangible and intangible resources (capacity, competence, image, trust) that the company possesses or is able to obtain from external subjects. The company creates value through all the processes that can create and protect

the competitive advantage and, therefore, through innovation, differentiation and communication. (Corvi, 2000, pp. 28-30).

The value of economic capital growth opportunities will subsequently be quantified based on the return of equity rate (ROE), generated by each initiative, by the length of time this profit is expected (n) and the potential growth rate (g). ROE is one of the most important indicators used to measure the performance of a company and calculated as the relation between the net profit gained by the company and equity capital, the latter standing for the financial contribution of shareholders to the business. The high yield of equity capital signifies that a small investment of the shareholders has been turned into a high profit and this is the main objective of the business done.

2.2 The effects of voluntary communication on the cost of capital (the major "disclosure" hypothesis)

The economic-financial communication does not consist only of a series of informational obligations required by the IAS/IFRS regulations, since companies deliberately choose to communicate to investors further information that is not required by the law and meant to acknowledge the fact that investors have brought capital to the business and they may need additional elements that would allow them to evaluate the company in the future.

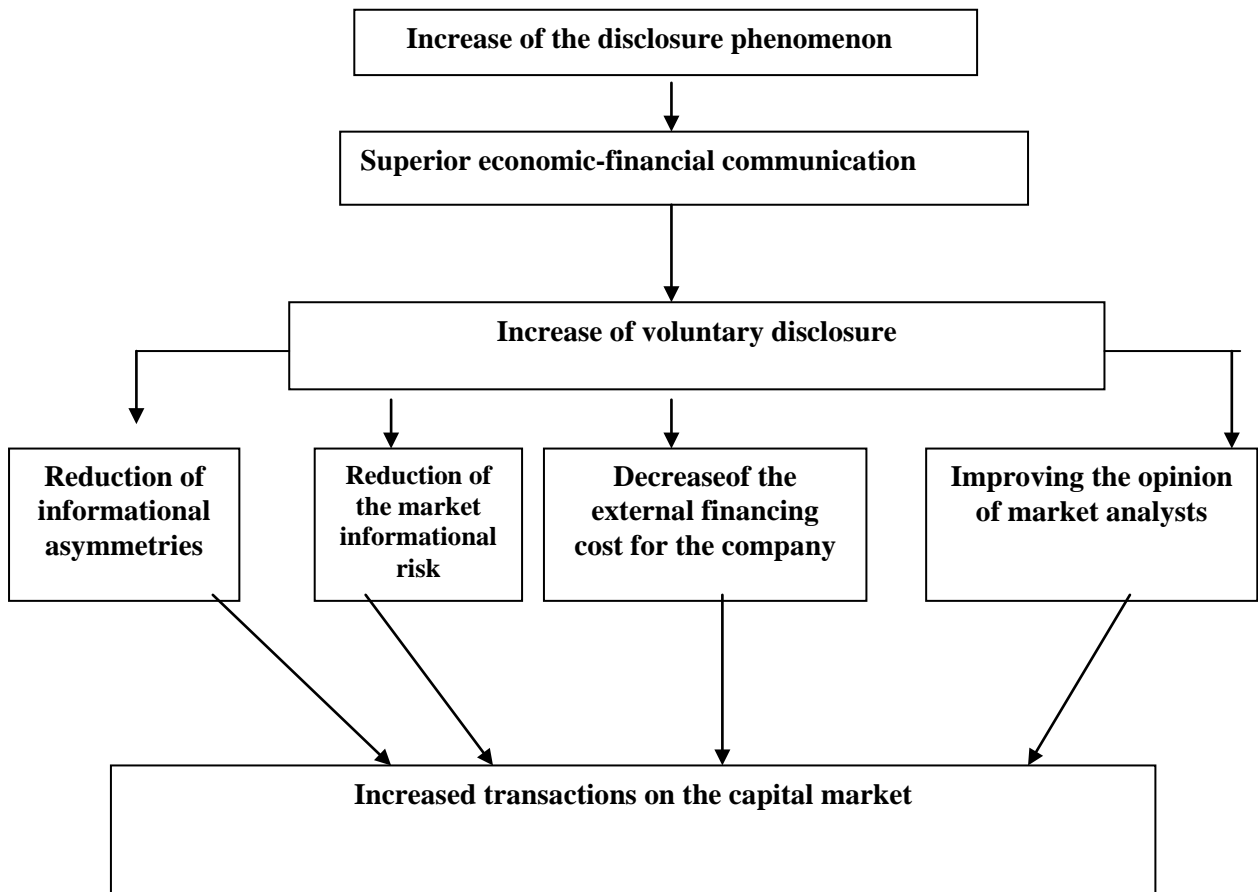

The reasons why the voluntary disclosure on certain hypotheses and transactions on the capital market hint at a major "disclosure" from companies heading towards the capital market and suggesting that these demeanours can provide benefits for companies, as concerns the cost of capital. In this respect, studies have shown that in companies that have taken an active interest in increasing their capital there has also been a significant increase in the reporting of information during the six months that have preceded the operation (Lang M., Ludholm R., 2000, pp. 623-662). Companies disclose more information about their economic-financial status, in order to reduce the transaction costs for investors and can, therefore, obtain a lower cost of capital as opposed to other companies that provide less information.

Gaining the trust of financial analysts is another important factor that leads to an increased frequency of companies heading for the capital market. (Healy, P.M., Hutton, A.P., Palepu, K.J., 1999, pp. 488-520). Moreover, in companies with favourable evaluations from analysts as far as financial communication ("disclosure" rating) is concerned, there has been a major informational contents of stock market prices (quotations of securities), considered as a correlation between the price of the share and the future profits, as compared to companies with a lower information level.

We can also emphasize the fact that the reduction of the cost of capital, as a result of voluntary informing, arises from the preference investors manifest for shares with a low estimation risk, limited transaction costs and a low level of informational asymmetry.

These three factors may actually be reduced by voluntary communication while a high demand for shares with such characteristics entail a higher price of securities correlated with a low cost of capital. We can thus highlight the fact that the increasing phenomenon of reporting information about the company may be briefly drafted in the scheme below:

Fig. 1 The influence of the increasing disclosure phenomenon on the company

This hypothesis on the estimation of the cost of capital, without the use of other variables as proxy, is being directly tested by an increasing group of researchers. The first empirical study conducted on the basis of this approach (Botosan, 1997, pp. 323-350) has tried to find negative correlations between

disclosure and the cost of capital by using an instantly created indicator to evaluate the financial reporting and to estimate the analyses on the cash flow and terminal values in order to forecast market expectations.

The results that have been obtained for a single task has thus revealed a negative correlation between the cost of capital and the voluntary disclosure in the case of companies benefiting from low coverage from financial analysts.

This study has been followed by other similar ones conducted by Canadian and Swiss companies that also support these results (Richardson and Welker, 2001, pp. 597-615; Hail, 2002, pp. 741-773); nevertheless, they must be carefully interpreted due to some criticism that has risen about the validity of the methods used.

The first refers to the effect of financial and social disclosure of the cost of capital and has thus highlighted a negative association between the quantity and the quality of the financial disclosure of the cost of capital contained in the annual financial statements of companies with low coverage from analysts.

The study has been conducted on a sample of non-financial Swiss companies and has revealed a negative and significant association between the disclosure quality, measured by an indicator that referred to the information provided by the annual financial statements, and the cost of capital.

As anticipated, both studies have variability issues, since they estimate the cost of capital by adopting a "discounted residual income" model (Gebhart and Lee, 2001, pp. 134-174) that leads to estimations of the cost of capital that are hardly related to risk, as revealed by further research (Botosan and Plumlee, 2002- A, pp. 123-141).

The effect of voluntary disclosure on the cost of capital in the financial sector has been supported by an analysis (Poshwale and Curtis, 2002, pp. 21-40) conducted on 135 European, American and Australian banking institutions, thus underlining the negative association between variables. The results have revealed that there is information related to risk management that highly influence the cost of capital, while European banks are subject to major reductions of the cost of capital as opposed to other companies included in the sample.

The contrasting results (Botosan and Plumlee, 2002-B, pp. 21-40) have also been revealed while analysing the relationship between the cost of capital and the ranking

made by analysts, concerning the various forms of corporate disclosure (annual and quarterly financial statements, public relations, investor relation), tested on a sample of companies operating in different sectors.

Thus, the empirical evidence has shown that this relationship is negative from the standpoint of the ranking according to financial statements, but it is positive (as opposed to the stated hypothesis), if we take into account the ranking of the quarterly statements and other public documents, as well as less significant as concerns the evaluation of the investor relation activity. This latter result arises from the hypotheses introduced by certain contradicting evidence that may derive from the failure to include certain forms of disclosure in the analyses and thus leading to different observations than what was expected. A possible explanation would emerge from certain relatively recent studies (Barron et al., 2005, pp. 404-420), suggesting that certain types of disclosure can further generate private disclosure and thus amplify the level of informational asymmetry and, consequently, the cost of capital.

Should this not be the case, the result obtained on the quarterly financial statements may be the consequence of a heightened interest that this type of disclosure has for institutional investors who abide by aggressive and short term investment policies (Bushee, 2000, pp. 171-202) and whose actions may increase the volatility of securities, with negative effects on the cost of capital.

3. Conclusions

As shown above, the activities performed by the company create value if their endeavours contribute to the long term sustainability and development of profit and if, at the same time, they influence the quality – and not just the quantity – of this profit, by reducing the variability or the inherent risks.

As far as communication is concerned, its benefits for creating value are justified, if we take into account the improvement of the company image, being fully aware of the fact that the manner of transmitting information through notoriety and combining the positive

image with positive notoriety is a synthetic, but very significant indicator of the value created by communication.

Innovation, differentiation and communication all contribute to the creation of value, thus generating opportunities of increasing the economic capital. Certainly, the contribution of communication to the creation of value can be described as follows: communication, as a collection of information, signals, symbols, behaviours and formal activities, significantly contributes to the image and notoriety of the company, given the common support of all its four branches – commercial, institutional, managerial and economic-financial, as well as the fact that, in order to create value for the company, a global approach of communication is of paramount importance. Communication conveys not only the value of economic capital, explicitly disclosing the real value on the market, but it also creates value, thus leading to an increase in the intangible assets of the company. By improving its relationship with the external environment, the company develops and acquires distinctive competencies and abilities, thus augmenting the credibility and feasibility in communicating with stakeholders, subsequently encouraging the development of its patrimony and creating a prolific cycle of value augmentation.

Insurance Risks – Hedging Techniques

Botea Elena Mihaela

gostanila@gmail.com

Abstract

Insurance companies by their specific activity and by the variety of operations are exposed to a multitude of risks. We can say that the risk is the basic condition of the insurance. If there were no risks, there would be no insurance. Therefore, risk insurance is a specific element, being subject to any insurance contract. Seeking a definition for risk, one can say that "risk is a danger, a threat faced by goods, people, businesses and insurance companies may provide". The insurance companies have to deal with specific risks as their field of activity: risks generated by undercutting premiums, incorrect sizing of technical reserves, unpredictable changes in the frequency of claims, an inadequate reinsurance and risk of general nature common to all types of businesses: incompetent management or maladministration development strategies, etc.

Key words: ART, Hedging, CAT bonds, pools, reinsurance

J.E.L. classification: G22

1. Introduction

Any insurance company wants to attract healthy and profitable businesses, but history is full of examples that do exactly the opposite, and those who not learn from past mistakes are doomed to repeat it.

In a market where the insurance companies reduce premiums, where relaxed and underwriting procedures are frequently used, it is compulsory to apply a hedging strategy. Competitive pressures generated

two reactions: the first one, the low-cost policy (or generous in terms of protection) resulted in a considerable reduction of their income, and the second one, the freezing policies (do not to the market changes) resulted in losing market share.

A sign of a new increasing capacity will relax the market prices.

In an example, a company is in real danger if this relaxation is combined with a defective calculation of reserves, with a lack of substantial financial investment income (in order to compensate all technical losses), with an anemic coverage through reinsurance, or with a loss to be recovered from a previous year. Some insurers are able to maintain technical underwriting criteria in such market phase, avoiding the reduction in commercial premiums, but paying special attention to the terms and conditions. Others have a sales force that behaves as if it understands the financial implications of the insurance rate of profits. Taking a subject with an adequate financial incentive is a possible answer.

2. Hedging techniques

In the last years, insurance companies have increasingly used more hedging techniques. Hedging techniques are aimed either at risks associated with assets or the risks associated with the debt or interaction between them, such as a ratio mismatch between liquidity risk and liability for the debts or assets (ALM risk).

Default hedging on debt maturity is achieved through processes of reinsurance (for primary insurer) or retrocession (for insurers), the issuance by catastrophe

bonds¹ (CAT bonds), through alternative risk transfer (ART) or carrying out transactions in financial derivatives.

Techniques reinsurance / retrocession

a) Reinsurance is the main mechanism by which insurers reduced their risk exposure. Through the process of reinsuring, the reinsurer agrees to indemnify an insurer, the assigner, against a total or partial damage that may support the latter in the original policy or in the policies they issued. Reinsurance provides a secondary spread risk, reducing the potential damage that can be attached to the reinsurers.

The reinsurance strategy greatly influences the underwriting policy of an insurance company on one hand, by allowing it to assume a greater number of risks and on the other hand, by reducing the insurer's exposure to a number of major damages.

Reinsurance can be provided by both specialized companies and direct insurers that are authorized to handle reinsurance contracts.

Reinsurance could be proportional or non proportional and concluded either on an optional basis (facultative reinsurance), either by treaty (treaty reinsurance).

b) Proportional reinsurance – A type of reinsurance where the ceding insurer cedes to its re-insurer a predetermined proportion of the liability and premium of those policies subject to the reinsurance agreement.

c) Facultative reinsurance – A form of reinsurance in which the terms, conditions, and reinsurance premium is individually negotiated between the insurer and the re-insurer. There is no obligation on the re-insurer to accept the risk or on the insurer to reinsure it if it is not considered necessary.

d) Non-proportional reinsurance - Generic description for those reinsurance contracts where the re-insurer agrees to provide coverage based on premiums and

claims which are not proportionate to those of the original risks taken on by the insurer. The contracts may be arranged as treaty reinsurance or on a facultative basis. Types of non proportional reinsurance include first loss, excess of loss, catastrophe loss or aggregate excess of loss, spread loss, and clash cover.

e) Treaty reinsurance – The reinsurance of a specified type or category of risks defined in a reinsurance agreement (a "treaty") between a primary insurer or other reinsured and a re-insurer. Typically, in treaty reinsurance, the primary insurer or reinsured is obligated to offer and the re-insurer is obligated to accept a specified portion of all such type or category of risks originally written by the primary insurer or reinsured.

f) In international practice along with basic methods presented above, were also outlined other methods: open covers, obligatory and facultative reinsurance pools.

Open covers methods and voluntary-mandatory agreements appeared as an answer to the continuous growth of the size of individual risks that affect all types of insurance.

The reinsurance market, such as voluntary-mandatory contracts are defined as those contracts signed between the transferor company and a re-insurer, the latter has to accept voluntary reinsurance yield to the other side. In terms of protections provided and the relationship between reinsured and re-insurer, the method is between the voluntary and mandatory methods. It is optional for the direct insurer that yields some risk of a re-insurer, in terms of which he himself is bound to decide the re-insurer to accept the proposed offer configured by the transferor company.

Reinsurance pools are owned by the participants of several companies, generating an independent entity that will cover the reinsurance business of a certain part of the risk underwritten by these companies, sometimes in exchange for the restitution of the member companies of the party that has initially accepted the risk. The management is provided by an alternate member, companies or joint venture, established by an organization with the primary task ceded reinsurance pool split between all members in the proportion agreed by them or assigned

¹ CAT bonds – are risk-linked securities that transfer a specified set of risks from a sponsor to investors. Catastrophe bonds emerged from a need by insurance companies to alleviate some of the risk they would face if a major catastrophe occurred, which would incur damages that they could not cover by the premiums, and returns from investments using the premiums, that they received. An insurance company issues bonds through an investment bank, which are then sold to investors.

to them in proportion with the volume of the business.

Restitution – the transaction whereby a re-insurer (retro) reinsures some of its risks (retrocession) by another re-insures (retrocession).

CAT bonds – Catastrophe bonds emerged from a need by insurance companies to alleviate some of the risk they would face if a major catastrophe occurred, which would incur damages that they could not cover by the premiums, and returns from investments using the premiums, that they received.

Alternative risk transfer (ART) is a generic expression used to reflect the various non-traditional forms of (re)insurance and techniques where risk is transferred to the capital markets. In a broad sense, it refers to the coverage of (re)insurance with banking and capital markets through financial reinsurance business, alternative risk financing, securitization, reinsurance of limited risk, weather derivatives.

ART is the last frontier towards the global insurance industry is heading. If this will be the future means to be seen, the fact is that this concept is still far by being operational on the Romanian market.

Alternative risk financing is a term that describes techniques that provide a different funding source for conventional (re)insurance. The insured could try to equalize his incomes for a period of several years by looking for a safe financing source in order to cover future damages and/or for ensuring his post-damage financing. The insurer taking the risk combines the low cash-flow risk technique and the actuarial risk analysis. These techniques include: financial reinsurance, finite reinsurance and contingent capital.

a) financial reinsurance – there is no clearly accepted definition, but financial reinsurance tends to refer to the value of money over time and the financial objectives, rather than transfer risk. It is intended to stabilize the balance of the assignor and to offer capital support. The assignor pays a prime in order to cover the damages (these damages are calculated on a multiannual basis, having a fixed maximum). The assignor beneficiaries of a credit increase improving his key rates, such as the combined rate.

b) finite reinsurance – is similar to the financial reinsurance, but implies a higher risk transfer. It is a retrospectively rated insurance, where the re-insurer's responsibility is limited. The multiannual contract allows the re-insurer to equalize the assignor's damages along the years, offering funds to cover the costs of the damage. The re-insurer will pay back these costs as stipulated in the contract. The assignor beneficiaries of a credit increase improving his key rates, such as the combined rate. The income generated by investments represents an underwriting component.

c) The contingent capital – is a post-damage financing method based on an agreement between a (re)insurer and a bank, through which the latter will offer a loan or funds after the triggering event has occurred. The bank receives a minimum amount for the prepared and awaiting funds. Contingent capital is less expensive than an ordinary (re)insurance in terms of paid costs, if the triggering event does never occur.

Weather derivatives represent a share, swap or option, whose value is directly linked to the weather condition for a certain period of time and a specific location. The weather derivatives are paid in cash depending on the event (significant temperature fluctuations, levels of precipitations)

Following a report by the Director General of Internal Market of the European Commission, we identified some of the advantages and disadvantages of this technique for each of the groups involved: the insurance company, the insured client and the regulator:

3. Financial derivatives

Hedging risk associated with assets as in ALM is achieved through the use of complex risk transfer mechanism such as the Collateralized Loan Obligations (CLO) and through the purchase of financial derivatives.

The transaction of financial derivatives it is considered to be one of the most efficient methods to maximize the profit and to minimize the risk in the portfolio management. Financial derivatives transactions have become the most popular mechanism to increase the performances of the portfolio.

In October 1977, in the U.S., the Commodity Futures Trading Commission gave the first definition for "hedging". Its main purpose was to reduce the risk that could appear in the following conditions:

- the change in value of an asset
- the change in value of a present or future debt
- the change in value of a service (provided or bought by a person in the present or in the future)

Risk management can not be conceived without involving financial derivatives that exist on the term market. When used in hedging operations, derivatives can protect or increase the value of a currency portfolio, depending on the purpose, either to hedge, or to increase the profit.

Although the investments on the derivatives markets are considered to be highly risky, the derivatives are used by insurance companies in order to eliminate risk. Their role is to transfer the risk from the spot market to the futures market. This allows an advanced management of the portfolio and generates important gain opportunities through speculative operations.

4. Conclusions

It is easily noticeable that in the international practice there are more than one method to hedge. Basically, each contract must be analyzed and dealt with individually. This is possible because of the infinite number of situations that the insurance or reinsurance companies must face. The method must be chosen depending on the operations particularities (size of the operation, profitability, associated risk, etc.)

Each company is unique and risk management should be customized according to their size, characteristics and complexity.

For the people working in the insurance and reinsurance field and professional and continuous training is mandatory. They permanently have to study the new risks, the appropriate hedging method so that both the insurer and the insured benefit.

Abstract

The insurance companies that concentrate a large amount of funds that they seek to invest on the financial market in the most cost effective manner. That is why, in order to face the competition and achieve their goals, the insurer must take into account the interdependency between the activity of subscribing and investment.

Today, the financial managers play a crucial role in every company; they have to provide good financial principles knowledge and also the latest innovations in the field.

Due to the unique financial structure asset, the financial department has a critical role in an insurance company.

Key words: risks management, scenarios, simulation, updated cash flows, sensitivity analysis

J.E.L. classification: G22

1. Introduction

Risk management is a relatively new field of insurance, providing a high interest and especially a practical unity.

Occurring in the United States, risk management has rapidly expanded around the world. It consists in adopting all the necessary measures to prevent damages and to limit all of them in order to ensure. It is of high importance for both the insured and the insurer, as follows, the insured person can benefit of reduced insurance premiums; the insurer takes all required measures in order to limit the financial losses that may occur.

Risk management is a process that has two types of objective. The first type of objective concerns pre-loss goals: the organization must prepare for potential losses in the most economical way, by analyzing the cost of safety programs, insurance premiums and costs determined by other methods of treating loss.

The second type of objective in risk management refers to post-loss objectives. The survival of an organization after a loss appeared is an example of such an objective, imposing the resumption, at least partially, of the activity in a reasonable period of time. Maintaining income after losses have appeared is another prerogative of the superior management of any organization, even if a perfect stabilization can not be achieved.

Nowadays, risk management consists of the totality of methods and means through which uncertainty is managed.

Risk management is not intended to eliminate risks. Risks are the main source of appearance of development and improvement opportunities. Superior advantages can be obtained by fructifying opportunities that appear by taking certain risks. A risk management program can help in making better funded decisions.

Risk management is being more often considered a general function of a company's management, whose objective is identifying, analyzing and controlling the causes and effects of uncertainties and risks that appear in an organization. Its purpose is to support the organization in order to progress towards

achieving its goals and objectives in the most efficient way.

This is why, in our days, risk management and insurances are essential for the understanding the fundamental changes that take place in the modern economy and for the developing strategic economic opportunities world wide.

The implications that the investing process has on entities, especially on insurance companies, determined by immobilizing big amounts of money for long periods of time have increased the cancers for developing preferment risk analyzing methods.

In this context, the possibility of approaching risk with the help of an analysis model is formed, model that is based on the sensitivity analyzing technique, script technique and decision tree technique.

2. The sensitivity analysis technique

The sensitivity analysis technique, also known as the "what if...?" technique, represents a method of studying the way certain conclusions, that have resulted from research, modify to the possible variations of values of the factors or to the errors.

Sensitivity analysis allows a better understanding of the risk that implies different kinds of actions and stability of the chosen decision maker.

It is interested to know the tolerance for some parameters, which does not affect adversely, or the achievement of expected levels of indicators.

The analysis can be used for any type of model, and because of the analyzing facilities it offers, many applications are realized by using „table calculating sheets” calculating types, which allow a very good visualization of the results through tables and graphics and it assists the decision makers in making decisions based on the formulated objectives.

Among the advantages this methods offers we can mention:

- it helps with making decisions and formulating recommendations because: it tests the robustness of the optimal solution; it identifies the critical values or the crisis point values when changes of strategy/optimal solution occur; it identifies the sensitive or important variables; it develops flexible recommendations depending on the

circumstances; it compares the values of a simple or complex decision making strategy.

- it facilitates communication by: making more creditable recommendations that are easy to comprehend; it helps the decision makers also incorporate other perspectives on the problem; it helps managers choose a certain approach when handling decision making problems.

- it increases the power of understanding of systems because: it estimates the relationship between the entry and exit variables; it develops hypothesis testing.

- it helps with model developing by: testing the accuracy and validity of models; it identifies the errors within the model, it simplifies and calibrates the model.

The sensitivity analysis undergoes two stages:

- taking in account the changes of each parameter, while the others remain unchanged;

- taking in consideration simulated changes of several variables and then the efficiency indicators are recalculated.

In order to analyze the results different graphics can be used, such as Tornado, Spider and sensitivity graphics.

The sensitivity analysis method describes the risks insurance companies confront, but it does not offer decision making criteria. The sensitivity analysis gives us a more detailed view on the possible evolution of the indicators, but the decision depends on the utility function of the investor or, more concretely, on his attitude towards risk.

Although sensitivity analysis is probably the most used risk analyzing technique, it has certain limits, taking in account that, in general, the risks of a insurance company don't depend only on the sensibility of the efficiency indicators to the variation of the variables, but also on the range of probable values of these variables, that is reflected by the probability distribution.

3. The scenario technique

In order to eliminate this disadvantage of the sensitivity analysis, the scenario analysis and the simulation technique were created. Making decisions based on the scenario method is founded on a distinct philosophy of the decision making process, namely, in order for decision making strategies not to be

vulnerable to unexpected events, the following are necessary: the explicit consideration of several possible evolutions of the "states of nature" and projecting, in consequence, a number of possible corresponding actions.

Because the scenario method is used for situations targeting a longer time span, ranging from decades to hundreds of years, it can also be used to calculate the solvability for insurance companies. This method takes in consideration both the sensibility of the indicators to the "key" variable variations and the probable range of the values of these variables.

In analyzing risks based in the scenario method, managers have to imagine a set of unfavorable circumstances, or a pessimistic scenario and a set of favorable circumstances, or an optimistic scenario. The indicators for each situation are calculated and then compared to the initial situation's indicators.

Exemplification of a model used to analyze sensitivity

The discounted cash flow technique can be used for both solvability testing and estimating the return of the investment of an insurance company, which is based on the idea of actualization of cost and future income. The technique is founded on the thesis according to which future cash flow has a greater value in actual terms because of the individuals' time preferences, which is usually positive.

The most popular techniques that are used in the actualization process are: the discounted net income (DNI) and the internal rate of return (IRR). Both techniques use the discount of all future net income flow and their sum. The discounted net flows include all incomes and payments, including interest and taxes, but not amortizations.

The discounted net income (DNI) calculates $DNI = Id - Cd$, where Id is the sum of the discounted incomes of the investment, and Cd represents the discounted investment and exploitation costs. When the net cash flow does not involve risk (or they have a risk already reflected in the interest rate), then any investment that assures a value of $DNI > 0$ is considered to be efficient, from an economical point of view. If more (mutually exclusive) investments are being analyzed,

by using the DNI the one of efficiency can be chosen $max.\{DNI_i > 0\}.i$

The Id value is deduced by discounting all the future values of the net cash flow income at their present equivalent, based on the interest rate.

When investments run for more years, Cd can include not only the initial investment, but also other costs integrated in the net cash flow of future periods.

In fundamenting an investment decision, sensitivity analysis is frequently used to identify the factors that have the most influence over the discounted net income (DNI), considered to be the most important economic efficiency indicator.

With the $DNI > 0$ decision making criteria being satisfied, in order to obtain a deeper analysis of investment running opportunities, it is necessary to do a sensitivity analysis in order to highlight the critical factors of influence in the formation of the net income. One of the sensitivity analysis advantages derives from the fact that it allows appreciations about the degree in which changes of different factors of influence (investments, prices etc.) affect the performance indicator used in the analysis (DNI).

In a successive sensitivity analysis (the modifications of only one variable are taken in account, the other parameters being constrained) subsequent disturbances are effectuated (small variations in a certain manageability domain) in order to study their effects on the DNI (the investor's performance indicator)

1. *Identifying the factors* which determine modifications of the DNI when it comes to an investment and estimating its value. In general, the elements whose information are available and are used in calculating the discounted net income are:

- the value of the investment (I)
- the annual sales volume (Q)
- the unit sales price (P)
- the cost plus the workforce per unit (L)
- the cost plus the raw and processed materials per unit
- the capital cost (represented by the discount rate or the interest rate in the case of credit financing) (r)
- the life span of the investment

2. Calculating the DNI for investments

In the previously mentioned hypothesis – the annual income is equal and constant in time, the formula for calculating the DNI is:

$$DNI = -I + Q [P-(L+M)] \cdot A^n_r$$

Where A^n_r represents the current value of an annuity factor and it expresses what value a sum of 1 u.m., spent or earned yearly on an n years type of horizon, has at the current time.

3. Determining the level of the factors for which $DNI = 0$

A relatively easy way to make a sensitivity analysis is to solve the equation $DNI = 0$ in relation with each relevant factor of influence; thus we obtain the "critical" values (XC) of the initial investment, the sales volume etc. which modify the character of the investment from a *possibly feasible* to a *potentially unfeasible* one.

4. Calculating the percentage difference of the calculated value of each factor, compared to the value initially estimated and analyzing the percentage difference obtained and identifying the most sensitive factor, which is the factor that at a very small percentage variation determines $DNI = 0$.

There are a couple of ways to build possible scenarios:

- the *optimistic* or *pessimistic* scenarios

- the *superoptimistic type of scenario*

where DNI is calculated for the most "favorable" values of random variables $DNI = f(\min Q_i, \max L_j)$ or the *superpessimistic type of scenario* where $DNI = f(\max Q_i, \min L_j)$.

Any of these scenarios allow the construction of DNI variation parameters and, eventually, the funding of operational calculus, in order to be able to answer a question of the following type: *what is the probability of this project becoming unfeasible (meaning $DNI < 0$)?*

4. The simulation technique

The word "simulation" comes from the Latin "simulation" which means the capacity to reproduce, represent or imitate something.

In the context of a quantitative approach of the decision making problems, to simulate means to reach the essence without reality because, generally, in order to simulate, a model of a real system is built and an experiment is realized on this model, in order

to achieve a better understanding of how the system behaves and/or evaluations of different strategies for the analyzed system.

Simulation is a computer using test technique and it implies the use of logical or mathematical models that describe the behavior of a real system on a big period of time.

Solving a decision making problem through simulation implies undergoing a few steps. The steps of the simulation generally follow the modeling cycle, but a simulation model is much more complex, because it implies the use of computers and statistical analysis. The most important steps in order to conduct a successful simulation can be grouped in four major fields:

- Problems that need to be solved
- Building the simulating model
- Conducting the simulation experiment
- Result analysis

In order to apply the simulation in the field of investment risk analysis, the following steps must be gone through:

1. Identifying the factors that influence the cash flow or, as appropriate, the duration of the investment and the relations between them.

2. Establishing the number and significance of the parameters and the random variables taken in consideration. The bigger their number, the more complicated it gets to solve the problem and the results are more susceptible to errors.

3. Formulating a model that can show the connections between factors and that respects the particularities of the field being analyzed.

4. The sensitivity analysis of the model, in order to identify the factors that have the biggest influence over the calculating indicators.

5. Determining the probability distribution of the important factors

6. Conducting the actual simulation.

7. Analyze the simulation's results, compare the results and choose the proffered option. The results obtained through simulation allow analyzing the risk and the uncertainty of a proposed variant. These results can take the form of probability distribution of the calculated indicators, of coefficient of correlation and regression that allow sensitivity analysis or reports of scenario analysis.

The actual simulation can be effectuated by choosing a simulation model type, among which we mention, the Monte Carlo simulation, the discrete event simulation, the Forrester type of simulation and the game type simulation.

For risk analysis associated with investments we recommend the use of the **Monte Carlo simulation**, in spite of the fact that it is more complicated than the sensitivity analysis and it needs a higher level of specialized knowledge.

Several methods and models can be found under the name of the Monte Carlo method, whose only common element consists in the sole fact that the real phenomena is replaced with an artificial one. In essence, the entire assembly of the real phenomena is replaced with a representative sample, approximating that the sample will give a pretty clear image on the whole.

In the past years, the best program packs based on the simulation technique are done based on spreadsheets, which have problem to be a very efficient and flexible method. This gives multiple advantages for simulating a system, for which time is not an important variable.

These advantages include the fact that they have a wide range of distribution (most companies must spreadsheets for activity reports), it involves a lower level of training, they incorporate many statistic functions and the results of the analysis can be developed, modified and displayed, in many cases, testing the model can be easily achieved and the time necessary for decision making is reduced.

The biggest advantage of spreadsheets is the possibility to simulate the effects of the decisions by the "What happens if...?" type of analysis without complicated models and extra programming efforts.

Based on the results provided by the simulation technique the following can be achieved: the analysis and comparison of the risk profits of an investment portfolio, comparison between the probability distribution of several investment options, the calculation and comparison between the averages and the dispersion of the indicators values, obtained after the simulation experiments.

5. Decision tree technique

Often, decisions are not isolated, but are arranged for a long time span and are inter-conditioned by the manifestation of random events. In these cases, the use of a decision tree type of analysis could be useful. This is a graphic way of presenting a chain of decisions and their results.

The main concepts used in the representation of the tree are:

- decision knots (represented through \square), that mark the starting points for the branches that represent decision alternatives. Characteristic for these knots is the fact that the choosing of the optimum alternatives is done by the decision maker; the option that is chosen is the one to which correspond the biggest expected medium income or the lowest losses, depending on the economic indicator used to compare the results.
- Uncertainty/event/chance type of knots (represented through \circ), in which state of nature branches are represented and whose values are calculated by using the expected value formula, based on probability and decision making consequences, associated with the state of nature that starts from every knot.

In order to identify the best option, the "roll-back" procedure is used. This means calculating the value that corresponds to each type of knot, starting from the end of the representation towards its start. Reading the solution implies determining a strategy through the tree and it is done starting with the initial knot towards the final ones.

The advantage of using the decision tree method is represented by the possibility to chain the decisional successions, but its disadvantage is generated by the tree constructing procedure, which is still laborious, in spite of the fact that it has been sustained by the appearance of preferment computer programs.

6. Conclusions

A specific domain of the general management, risk management targets reducing the probability and consequences of damages caused by accidents that insurance agencies have to deal with.

In Romania, the awareness levels of the necessity of risk management are still low. Companies are required by law to ensure occupational safety of the employees and often forget to protect their goods and the activity they carry on. As consequence, economic agents are not prepared in case of accidental events with grave financial implications.

The cost for implementing risk management techniques is incomparably lower than the damage value with which people or companies can confront, especially in the case of natural disasters.

The efficiency of using risk management methods and techniques is proven by the reduction in the numbers of accidents, in the value of repairing expenses, in the income loss determined by ceasing activity and production delays.

In conclusion, the use of risk management in a company's activity is required by the laws of market economy, promoters of competitiveness and profitability of businesses.

The Controversial Activity of Multinational Companies

Botescu Ion

Negoescu Gheorghe

„Ovidius” University of Constanta, Faculty of Economic Sciences

ion_botescu@yahoo.com

Abstract

Having put their two cents in highlighting the economical interdependency process on a global level, the great multinationals are characterized by some as economical invaders and as the main development promoters in developing countries, by others. Multinational companies have sequentially followed the liberalization of commercial trades and of the capital flow movements, proclaiming to be interested in a least regulated international economical environment. Multinationals aim at maintaining a turbulence free international climate, which allows them to streamline their economical activity.

Key words: multinational companies, foreign direct investments, globalization, subsidiaries..

J.E.L. classification.: F 23

1. Introduction

In the last few decades, multinational companies have become the main source of private capital for most countries, through foreign direct investments (FDI).

It is important to assert that FDI does not create external debts for the country referred to and the capital outflow involved (repatriation of profits) depends on the enterprise's economical results and replies to the investor's interest as well as the interests of the state that encourages the economical growth.

The activities undertaken by multinational companies are complex and their impact on host countries is much greater than we are led to believe by statistic data. Their indirect effect is reflected on demands made to national enterprises, on creating new working places, on encouraging horizontal industries,

carrying out indirect exports a.s.o. We can, thus, state that FDI has become more and more important for production, trade, technology transfer and capital flows in the global economy and, that multinational companies are playing a more significant role in the economies of host countries. Today, FDI is manifested as a powerful force in the process of boosting the efficiency of resource allocation, on a global level, and as a channel for conveying economical input related to production, technology and quality of work.

2. The conflicting effects generated by multinational companies' activity

Foreign direct investments may be considered a driving factor for insuring competitiveness, where multinational companies raise the bar on the complexity of production in their foreign branches, from simple assembly operations to more complex operations, by using new technologies which they integrate in their external production network.

The beneficial effects of the multinationals' actions are less obvious in developed countries, seeing as how developing countries, those in South-Eastern Europe and members of the CIS, receive 30.0% (valid figure for the period between 2000 and 2008) of the international FDI flow. In the case of the host country, most often, the branch owned by the multinational company contributes more than the domestic company to the betterment of the professional training level in the work force, to the research-development activity or the productivity growth of the relative domain.

Multinational companies contribute greatly to the development of capital in host countries. Through investments, they create new working places, generating higher salaries than local enterprises. Moreover,

local suppliers are presented with the possibility to obtain better income.

While doing business with local enterprises, multinationals transfer onto them a series of knowledge, sometimes offering them technical and financial assistance. Concurrently they influence the strategies adopted by local firms, their entrepreneurial spirit and their orientation towards exports, having a fair impact on the efficiency of the economical activities in the host country.

FDI contribute to the integration of less developed countries in the global economy, stimulating international trade, especially by importing vehicles, hardware and equipment. Along with external trade, multinationals also stimulate the supply of services, necessary to international trade (banking, insurance, transportation and telecommunication services) that contribute to the economical growth of the host countries.

Multinational companies have made it possible to infiltrate less developed countries with low priced products, fact which is closely connected to the betterment of the standard of living in many parts of the world. Also, these companies have created conditions, on markets pertaining to developed countries, for the boom in exports with manufactured products originating from developing countries.

There were many discussions on the relation between the multinational company and the host country. This mostly depends on the group of states (developed or developing) in which the host country is included. When host countries have a high economical potential, multinationals tend to drive at applying the mutual advantage principle, while taking into consideration the perspective of obtaining a good profit as well as strong competition between investors. When host countries are developing countries, multinational companies become more influent in their relationship with the governments of those particular states. This happens due to the lack of an adequate legislative framework in the host country, and is enhanced by the myriad of corruption deeds. In less developed countries, multinationals try to compensate deficiencies resulted from high inflation, monetary and political instability etc., with a series of opportunities given by cheap labor, generous

natural resources and easy access to the local markets.

Multinationals locate their branches in those countries that offer the best of developing conditions. On the other hand, potential host countries are interested in attracting multinational companies, and use a series of means of servicing: stimulatory regulations, the stability of the legislative framework, building roadways, railroads, water supply systems etc. basically, a multinational company cannot activate in a hostile environment, but no host country determine a multinational company to forcibly open a branch on its territory. There has to be a mutual agreement, based on the ability of the multinational to produce positive value. The multinational must be content with the profit influx, and the host country must be content with the advantages brought on by taxation, work force occupancy and, last but not least, economical growth.

Multinationals stand at the origins of many positive aspects generated, as they are the main vectors of globalization.

Still, we cannot ignore the deficiencies generated by the activity employed by multinationals in various states, mainly developing countries.

The first shortcoming arises from the allocation of wealth between the multinational and the host countries. This depends on the tax rate levied by the hosting government and the regulations in that sector. One of the most grievous measures against foreign companies would be to tighten up the rules of the game after the multinational company already set up shop in the host country. It is very possible that the multinational will draw back from that arrangement, raising a red flag for other potential foreign investors.

Trade policy measures that are supported by the host country may lead to issues with the multinational firms that have branches on those particular territories. Normally and traditionally, due to their competitiveness, multinationals excel at promoting liberalization in international trade. Paradoxically, in limited cases, some multinationals, encourage the host countries to practice protective policies to limit imports. In such cases its more profitable for multinational companies to open productive

branches in the host country than export their own products, even given the host government's intention of liberalizing international trade relations.

The host countries' concern to generate more working places, manufacture products with higher added value and ultimately to cash in more budget income, drives them to condition assignment of facilities for the growth of the integration level of production, achieved by multinational companies' branches. This is how conflicts are born, with multinational companies, because there are situations where maximization of profit is achieved through assemblage of components within the branches in the host country.

The unorthodox fluctuations in the exchange rate registered by the national currency of the host country in relation to the main currencies may use deficiency for the multinational firms. For example, with the depreciation of the national currency, even if exports are stimulated, multinational branches that produce for the domestic demands of the state they inhabit, are forced to pay more for the import of limbs or parts that compose the end product, due to the precipitation of the currency risk.

Aggressive and discriminating behavior toward the employees of the foreign branches is just one of the various problems that should attract responsibility from multinational companies' managers. Most managers that have acted inadequately or even illegally in their affairs with host countries benefit from corporate immunity and walked away unreformed or facing minor charges, because the registered offices of multinational companies are located abroad. A graphic example is the case of Exxon, whose oil carrier, Valdez, hit the beach in 1989, causing one of the gravest marine pollution in history. The value of the damages was estimated at several billion dollars. The culprit was the boat's captain, who coordinated a faulty course, as he was intoxicated at the time. The penalty he received was a knock-out price to pay: a fine for \$51.000 and 1000 hours of community service, collecting garbage.

Organizing multinationals in the shape of limited liability trading companies allows them to claim huge profits; because the worst owners risk to lose is the amount they contributed with for the establishment or

development of the respective legal entity. Hence, a company opens a factory for the production of blacking. After several years of activity, when the effects on the environment become eloquent and larger numbers of the employees and local inhabitants begin having health problems due to pollution, the owners of the firms that cumulated substantial income file for bankruptcy. They are exempted from responsibility of invest in environmental betterment in the area as well as from bringing material compensation to those whose health was affected.

The tension between multinationals and host governments may occur from reasons of insecurity. Manu American who companies extract oil from Nigeria had temporarily ceased their activity, until the Nigerian government sent troops that eliminated the ethnic conflicts in the area.

In order to reach their objectives, multinational companies use an arsenal of instruments to condition host governments to proceed accordingly. Amongst the means used we might mention: employing lobbyists, aggressive advertising (such as the case of Rosia Montana) to influence public perception and decision makers, using bribe and corruption to constrict governmental agents into satisfying the interests of the respective trading companies.

3. The need to improve the attitude of multinational companies

Regularly, there are a series of measures meant to restrict deficiencies brought to multinational companies, mostly implemented in less developed countries, such as:

The salience of social responsibility

Practice shows that there is a direct line between a multinational's cultural value and the actions it unfolds, where social responsibility is concerned.

Notably, the actions undertaken by a multinational company must be voluntary in order to be catalogued in the social responsibility area, and not be a consequence of applying legal care.

Multinationals have established amicable relationships with communities where they activate and attracted positive appreciation

from members of the community, many of whom wish to work for the referred to companies, by treating their employees, partners and shareholders fairly, and paying attention to the environment.

Contrariwise, even if efficient economically speaking, companies that have a tense connection with the members of the community and who negatively affect the environment where they activate, may record, due to the bad reputation surrounding them, a drop in value of shares traded on the stock market.

For wanting to have a higher profit rate on the longer term, companies are in pursuit of eliminating competition on the market they are activating on, or make settlements with businesses they are competing with in order to set prices high. Developed countries have established a well defined legal frame, in order to protect their consumers, which implements criminal correction, as well as the payment of substantial material compensation by those who displayed an anti-competitive attitude.

The globalization of the economical world brought on the surfacing of monopolist trends on an international level. Anti-competitive behavior in international affairs is much harder to refute in the absence of some special interstate regulations. Moreover, in their national legislation, developing countries don't generally envisage measures to limit monopolist trends. If developed countries adopted along the years laws to protect their citizens from the anti- competitive manifestations on the part of multinational companies, when it comes to their governments' involvement in international affairs, they will support their own entrepreneurs, most often than not, in order to reach monopolist agreements that will ensure higher profit. It is evident that developed countries apply a discriminatory standard regarding the inhabitants of economically underdeveloped countries, unlike that displayed on their own citizens.

Thus, it is commanded that besides adopting anti-monopoly and anti-cartel laws, there be the establishment of institutions that handle the regulations of these aspects globally, track down anti-competitive practices and apply coercive and restoring measures in the field.

The perfection of the corporate legislation

Corporate legislation must mainly ensure the possibility of applying criminal justice to transgressing managers. Just as managers must capitally answer for their actions facing shareholders, they must also capitally answer for the damage inflicted on employees and the pollution of the environment.

Secondly, corporate legislation must ensure the payment of restoring damages done by guilty parties. For prejudice brought abroad, multinational companies are usually brought to court in the host country. Although the complainants are given satisfaction, on the basis of fair trials, they cannot restore their prejudice because the multinational is either represented by a branch that files for bankruptcy, or own too few properties that can be executed. Multinational companies' shareholders, who most often stand to gain hugely from activities that take place abroad, cannot be held responsible for prejudice brought in the host country because they are under the m of limited responsibility and generally leave real ecological disasters behind.

Among others, there should be a possibility for the multinational to be brought to trial in the mother country, which is generally a developed country, and be tried based on national standards on environment, health etc.

Fraud duress

High frequency and notoriety have become defining notions for: corruption, dishonest agreements regarding prices, illegal material contributions for political parties, tax evasion, breaking the antitrust law and even murder.

We should notice that the range of corruption includes: bride, nepotism, fraud, embezzlement, the use of others' resources, harassment etc.

Even if corruption is more widely known in developing countries, it takes other, more sophisticated forms in developed countries. In these notorious states, we find electoral campaign financed by extremely powerful multinationals. The amount of money reclaimed by corporations after such financed politicians issue favored laws, are several times the amount spent.

US' issue of the law regarding corruption abroad is estimable and should be adopted by as many countries as possible. Some American corporations reflect on this legislative action, because they consider they are entering disloyal competitions for investment bids on international markets with companies that reside in countries where bribe is accepted.

The amounts deposited in banks, especially in tax heaven and derived from acts of corruption are hard to identify because of bank secrecy. The use of funds protected by bank secrecy for the financing of the terrorist acts of September 2011 in the US, led to promoting regulations against bank secrecy policies when it comes to terrorism. This attitude regarding bank secrecy should also be in. it would seem that certain strategic arguments are delaying them from taking that initiative. This subject, of renouncing bank secrecy, in other cases than concerning terrorism should be debated within the OMC, but the same strategic arguments make it intangible for now.

4. Conclusion

Multinational companies tend to concentrate on countries with better perspectives of economical growth what have natural resources, large internal markets, well trained and relatively cheap work force, a favorable legislative assembly etc. They also influence these countries' ability of development in turn. Interdependency and integration, but also the need for righteous footing, implies permanent interaction between hosting governments and multinationals, based on the principle of mutual advantage.

Currently, the multinational companies' network and their worldwide branches form an integrated system, with common economical, social and ethical values and play a leading role in the evolution of global economy in the main and within each country in particular.

Corporate Social Responsibility (CSR) - a Theoretical Approach

Bradu Cosmina Paula

„Alexandru Ioan Cuza” University of Iași, Doctoral School of Economics
cosminabradu@yahoo.com

Abstract

In the last years the expectations towards CSR are increasing and with this also the demand that businesses behave in a socially responsibly manner. But we should not forget that Corporate Social Responsibility (CSR) is a contested and also evolving concept, fact that is evidenced also by the different points of view concerning the definition and also by the lack of consensus about why it might be a worthy marketing objective.

This article aims to illustrate the main concepts and frameworks regarding the corporate social responsibility (CSR) and the expectations towards it.

Key words: *Corporate social responsibility, consumer`s expectations*

J.E.L. classification: M14

1. Introduction

The corporate social responsibility (CSR) is a concept that has become more and more important in the past years and that has a long history. This importance is also reflected in the public relations and marketing literature (Kotler and Lee, 2005; Maignan et al., 2005).

Different research studies have focused on clarifying and developing the concept but also on attitudes and reactions to CSR (Sen and Bhattacharya, 2001). The expectations toward the corporate social responsibility (CSR) are increasing and they have become an important driver of public opinion and reputation.

Also, looking through the definitions given to this concept CSR, ideas appear to have developed in contrasting ways in different parts of the world (Welford 2004 and 2005).

2. Corporate social responsibility (CSR)

Definitions of corporate social responsibility (CSR) first have appeared in USA in the 1950`s (Carroll 1991).

During the following years efforts have been made to clarify and develop this concept. The first definitions focused on the connection between `business responsibility` and `business power`.

By the 1980`s the focus shifted from developing new definitions to further research on CSR and his dimensions.

All these definitions have in common the idea of the stakeholder expectations and social preoccupation.

The basic idea is that no company can afford to act against society (Matten and Moon, 2005).

During the last years, interpretations have developed from a focused concept to a more broader to a more broadly conceived notion that attempts to combine and balance economic, social and environmental commitments as part of a drive towards sustainable development or sustainability (Acutt et al. 2004).

Therefore, the use of the term CSR has not been diminished and furthermore its core concerns have been recast into alternative theories, concept models and themes (Habisch and Jonker, 2005).

CSR refers to the contribution that the companies have to give to the development of the modern society.

Because of the various definitions given to this concept there are also a lot of interpretations.

They range from the neo-classical economics definitions to the definitions that embrace the idea that the company is a `citizen` that have social goals.

For the neo-classical perspective Milton`s Friedman view of CSR is: "to conduct the business in accordance with [owners' or

shareholders] desires, which generally will be to make as much money as possible while conforming to the basic rules of society, both those embodied in law and those embodied in local custom" (Friedman 1970). He argues that only people can have responsibilities and not companies. An argument that sustains this theory is that there are a lot of empirical tests that could not find a direct relationship between CSR activities and the financial performance indicators in a company (e.g. Agle, Mitchell and Sonnenfeld, 1999). But there must be underlined the fact that it is very difficult to quantify the social corporate performance. This fact was highlighted also by Agle (1999): "The social corporate performance is famous because it is difficult to quantify".

Yet, in present the general tendency is to adopt the corporate social responsibility (CSR) concept, the critics of the Friedman's Theory sustaining that he had a narrowed perspective, focusing only on the business itself and not taking into account all the benefits that can be brought by the CSR activities.

Also in the literature are a lot of definitions, each of them illustrating the advantages of this concept.

The European Commission's definition of CSR is: "A concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis."

Also the European Commission presents the main obstacles in the development of CSR:

- insufficient knowledge of the relationship between CSR and business performance;
- insufficient knowledge of the CSR concept on the part of consumers and investors;
- the lack of a consensus concerning the general CSR concept arising from differences between Member States;
- insufficient emphasis on CSR in university education;
- lack of resources for actions to promote CSR in small and medium-sized enterprises (SMEs);
- a lack of instruments to communicate and administer CSR activities;

- a lack of a coherent strategy by public authorities.

Corporate Social Responsibility is part of the Europe 2020 strategy for smart, sustainable and inclusive growth. It can help to shape the kind of competitiveness model that Europe wants (European Commission).

More specifically, Jennings and Zandbergen (1995) analyze the role of institutions in shaping the consensus within a firm regarding the establishment of an "ecologically sustainable" organization.

Baron (2001) defines CSR as the "private provision of a public good." More importantly, Baron (2001) asserts that companies compete for socially responsible customers by explicitly linking their social contribution to product sales.

In Kotler & Lee's book (2005, p. 3), "corporate social responsibility is a commitment to improve community well-being through discretionary business practices and contributions of corporate resources".

The same authors consider that "corporate social initiatives are major activities undertaken by a corporation to support social causes and to fulfil commitments to corporate social responsibility".

Table 1- Corporate Social Initiatives

Marketing Related Social Initiatives	Non- Marketing Related Social Initiatives
<ul style="list-style-type: none"> • Cause Promotions • Cause-Related Marketing • Corporate Social Marketing 	<ul style="list-style-type: none"> • Corporate Philanthropy • Employee Volunteering in the Community • Social Responsibly Business

Source: Kotler and Lee 2005

Also Kotler and Lee (2005, p. 22 – 24) describe the following initiatives:

Cause Promotions: A corporation provides different resources to promote a social cause or to support fundraising, participation, or volunteer recruitment for a cause.

Cause-Related Marketing: A corporation commits to making a contribution/donation to a cause based on product sales, usually for

a specific period of time and for a specified charity.

Corporate Social Marketing: A corporation supports a change campaign intended to improve public health, safety, the environment, or community well-being.

Corporate Philanthropy: A corporation makes a direct contribution to a charity or cause, most often in the form of cash grants, donations, and/or in-kind services. This initiative is perhaps the most traditional of all corporate social initiatives and for many decades was approached in a responsive, even ad-hoc manner, but more corporations are now experiencing pressures, both internally and externally, to move towards a more strategic approach, choosing a focus and tying philanthropic activities to the company's business goals and objectives.

Community Volunteering: A corporation supports and encourages employees, retail partners, and/or franchise members to volunteer their time to support local community organizations and causes.

Socially Responsible Business Practices: A corporation adopts and even conducts discretionary business practices and investments that support social causes to improve community well-being and protect the environment.

Kotler and Lee (2005:3-4) also list various causes that business's support in contributing beneficially to society, including:

- Health;
- Safety;
- Education;
- Employment;
- The Environment
- Community and Economic Development

Finally, a recent paper by Waldman, Siegel, and Javidan (2005) applies strategic leadership theory to CSR. They conjecture that some aspects of transformational leadership will be positively correlated with the engagement in CSR and that these leaders will employ CSR activities strategically.

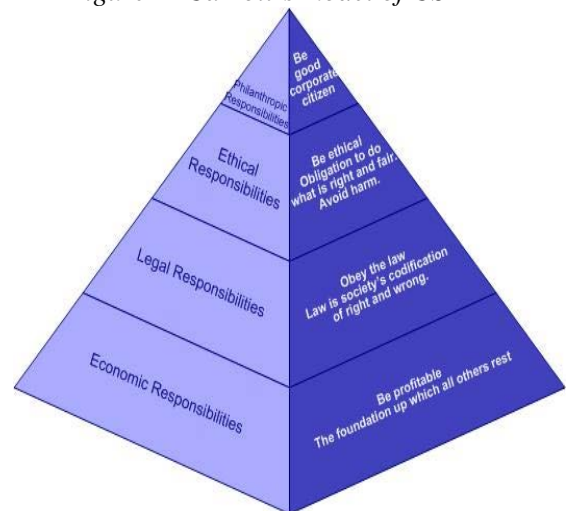

Despite a variety of different types of CSR definitions in the field of management and marketing (De Bakker et al., 2005; Maignan et al., 2005), the most widely accepted definition seems to be Carroll's (1979, 1991) which is often used both by the management

and marketing scholars (Abratt and Sacks, 1988; Aupperle et al., 1985; Maignan, 2001).

The reason for its acceptance can be that the CSR concept is really broad and problematic in terms of drawing up a definite list of issues which constitute CSR (Evuleocha, 2005).

Carroll (1979) defined CSR based on normative arguments and suggested that a company has to fulfill four main responsibilities. Hence, the definition encompasses "the economic, legal, ethical and discretionary expectations that society has of organizations at a given point of time" (Carroll, 1979, p. 500).

Figure 1- Carroll's model of CSR

Carroll's CSR Pyramid

Source: Carroll 1979

In the model proposed by Carroll (1979, 1991), the definition of the corporate social performance should comprise three articulated and interrelated aspects (1979, p. 499): a basic definition of the total social responsibilities of a company, an enumeration of the issues for which a social responsibility exists, and a specification of the philosophy of corporate response to social pressures ("social responsiveness").

Considering the first aspect mentioned, an exhaustive definition of corporate social responsibility should emphasize the whole range of social obligations a business has to society: economic, legal, ethical and philanthropic (discretionary) responsibilities.

These four types of social responsibilities form the concept of corporate social responsibility (CSR) in the vision of Carroll, and they should be analyzed together.

According to Carroll (1979, 1991), the corporate social responsibility is more than complying with economic and legal obligations; it also includes ethical and philanthropic responsibilities as another two dimensions.

3. Conclusions

Despite the multitude of possible approaches, we can identify a few main characteristics, based on which other concepts or attitudes can be defined. The following are the most important:

- CSR expects that organizations voluntarily carry out measures through which they can contribute to solving social and ecological problems;

- There is a strong connection between CSR and the concept of long term development, determined by the fact that organizations have to include the economic, the social and the environmental impacts in every one of their actions;

- CSR related actions are not an optional "accessory" for a business' main activity (mainly about the way in which business' are managed);

- CSR related actions are not just about simple money donations carried out through charitable events. The main difference between CSR and charity is that CSR includes the development of a strategy regarding the company's involvement and a partnership with the community, which can be of great benefit for the company;

- This way we can talk about a partnership from which every member has something to gain;

- The reasons why companies get involved in CSR programmes are selflessness, personal interest, commercial spirit, competitiveness, or any of these reasons combined.

I consider that corporate social responsibility is important for the company's success for at least three reasons:

1. it improves the organization's image because it has to adopt an ethical behaviour and create benefits for the society;
2. it improves the organization's image because it has to adopt an ethical behaviour and create benefits for the society;
3. during a crisis situation, the company will benefit from higher credibility;
4. the organization benefits from a different type of publicity.

CSR is becoming a priority for the managers of the Romanian companies and for the managers of companies around the world. The continuous development of companies with ethical, community and social boundaries is becoming more and more important in the global business culture.

Still, the sustained corporate development concept is controversial, by definition and by indicators used to measure the degree of corporate involvement or by efficiency of the CSR strategies and initiatives.

Interest and Role of the Economic and Financial Analysis in the System of Management Sciences

Abstract

The financial analysis is a discipline that belongs with accounting, management control, auditing, etc.. in the category of management sciences. This paper aims to highlight the importance of this discipline into the management sciences

Economic and financial analysis contribute to develop future professionals thought, to enhance their ability to understand complex economic and financial phenomena, supporting them in an effort to explain, scientific assessment, diagnosis and resolution of the various situations occurring in the enterprise.

Increasing the role of economic and financial analysis as an indispensable tool in the diagnosis and control functions of any economic unit, training and decision-making requires a systemic approach, presentation of factorial mechanisms, the casual intimacies of economic phenomena and processes. From here, we conclude that economic and financial analysis is a discipline of basic science management system, a performance management in any field of activity and an essential condition for development and implementation of decisions.

Key words: financial analysis, management science, financial analyst

J.E.L classification: M41

1. Introduction

Like all management disciplines financial analysis is in perpetual development.

The organization must have the ability to adapt to the economic environment and improve economic and financial performance. Thus, economic-financial analysis has the role of investigating economic phenomena and processes, to establish causal relationships, the factors that generate them and basing on this, taking decisions for future activities of the enterprise.

2. The meaning of financial analysis

„Economic and financial analysis is a set of concepts, techniques and tools that provide internal and external information processing, for formulating relevant assessments on the situation of an economic agent, the level and quality of its performance, the degree of risk in a competitive environment extremely dynamic.” [1]. Thus defined, financial and economic analysis integrates three meanings: analysis as a subject, analysis as a scientific research and analysis as practice.

The financial economic analysis contribute in knowing the efficiency of using human, material and financial resources by the knowledge of current forecast. Its complex character, based on the cause-effect relationship, comes from the following reasons:

- the same effect can be generated by different causes;
- different effects can be combined, giving a resultant complex actions or forces;
- intensity and complexity of cause can determine not only the intensity of the phenomenon, but also its quality

- in the analyzed phenomenon can appear characteristics which were not present in none of the phenomenon elements

- in the objective reality, the essential characteristics can be combined with the non-essential, secondary or incidental [2].

"Economic and financial analysis is above all a science of interpretation, interpretation based on a system of information to be collected, treated, processed. In terms of reliable and accurate information, pertinent formulation of value judgments depends on the extent to which the analyst knows the economic theory, knows the objective reality and the experience accumulated by it" [3]. According to Norbert Wiener's consideration "the concept of amount of information links in a quite natural way of [...] the concept of entropy. As the amount of information in a system is a measure of the degree of its organization, so the entropy of a system is the measure of the degree of disorganization, an equal one with the other taken with opposite sign"[4], we can conclude that the lack of information leads to the instability of the system and creates disorganization inside of it.

Users of financial and economic analysis is an important category in the communication process and information processing.

This category has varied over time being influenced by social, economic and cultural specific to each country. Thus, the information provided in the XIXth century economic and financial analysis mainly addressed leaders and business owners in our century, while its coverage area has expanded greatly.

The objectives of economic and financial analysis is highly complex, arising from the variety positions occupied by those who realized it and as a consequence, the diversity views and information they have access.

When the problem of analysis is made within the firm we have the internal financial and economic analysis. It is addressed to:
- managers, shareholders or employees and has as objective the detection of possible weakening of the financial situations in order to identify the origin and causes that have generated them and determining remedial measures. Because it is based on the entire system of information on business activities, internal analysis addresses issues regarding:

the size and structure of assets, performance, risk and provide the information necessary for business management decisions.

When the problem of analysis is made outside the company, we have the external review and its users will be: creditors, business partners, financial analysts, potential investors, or even the state. The classic example is the procedure used by banks for the study of loan requests of firms. On this occasion they follow the company's ability to pay its obligations and grants, in this context, particular consideration to enterprise value, liquidity and solvency of analysis.

Local or central government bodies use financial analysis, on one hand, for the knowledge of the situation of the enterprises which call for financial incentives, and secondly to determine their potential to pay taxes. Economic and financial analysis, is also an essential component in an expertise or a negotiation aimed at estimating the value of an enterprise during privatization, merger, sale of assets, stock exchange listing, etc. Evolution of economic and financial of analysis must adjust objectives or needs of different users. In this case, the analysis involves for the analysts in addition to accounting and financial management knowledge a certain subtlety in interpreting the figures reported for investigation.

Agreed consultants and auditors use the analysis as the working tool used in missions to inform and protect the legal fund providers and creditors.

3. The domains of financial analysis

To underline the importance of financial analysis, I will present in the following chart the users of the information:

Chart no.1

The users of financial – accounting information	Internal	Management of the company	
		Employees	
	External	The donors of the company: - stock donors (if publicly traded companies); - bank financing (enterprise resources come from bank loans); - public power by the quality investor in RAs; - other types of financing (leasing contracts).	
		Commercial partners: - suppliers - clients	
		Unions	
		The public	
		The state	

Areas of financial analysis in relation to its partners are presented in the following chart:

Chart no.2

Crt. No	Analys is type	The informat ion users	Decisions made based on the information
1	Strategic Analysis Performance review Analysis of financial position	The managers The boarding administration	Decision: Strategic Investment, Financing
2	Treasury Analysis Risk Analysis Profitability analysis	Investors	Decision to invest

3	Solvency analysis Risk Analysis Profitability analysis	Creditors	The decision to grant credits
4	Treasury analysis Solvency analysis Risk analysis on a certain field of activity	Suppliers	The decision to work with the analysed enterprise
5	Strategic Analysis Stability analysis (Continuing activity)	Clients	The decision for supplying The decision to sell Strategical decision
6	Stability analysis Analysis of human potential	State	Decisions on fiscal policy and economic policy
7	Stability analysis Analysis of company performance	Financial analysts	Fundamentat ion of strategic decisions

4. Economic and financial analyst job

Today economic and financial analyst profession plays an increasingly more important. Individuals with such expertise should be "a professional of figures who makes account speak" [5] thus providing a critical analysis of financial situation of the enterprise which would be the basis for the formulation of judgments about the business. The financial analyst may be regarded as one of the categories of users for financial accounting information. In the specialized literature they are considered an intermediate category because information processing and interpretation of financial accounting information is done for another customer [6].

Financial analysts are being employed in an enterprise, whether they services for banks, brokers, using specific tools to the analysis accounting and information obtained from accounting and extraaccounting sources.

In their work as a financial analyst, it must:

- to use the relevant accounting and financial documents
- to determine needs and objectives of business partners;
- to choose your specific analysis tools for the proposed object. These methods of analysis can be traditional or modern;
- to give importance to the processes of globalization of markets and harmonization of accounting;
- to show obedience to the rules of professional ethics and deontology.

The financial analyst must seek to meet the satisfying of informational needs for each category of users, because the elements of financial situation do not have the same relevance for all category of users.

When a company secures financing through banks, the analysis must address their needs through the study of debt repayment capacity of the enterprise. In this case we have a credit analysis.

Employees, customers, suppliers are interested in: the risk of bankruptcy of the company, their vulnerability and not least of ability to continue business operations.

The credit analyst relies primarily on traditional analysis tools, following the repayment capacity of the company. He calls for adjustments to present a real case of the activity of the enterprise, because synthesis documents usually show a flattering image regarding the financial position and the performances of the company.

From investors point of view, the analyst must play an intermediary role between the company and capital markets. In this case the financial analyst can be called market analyst. Market analyst with main concern the understanding and anticipating the market reactions, he uses traditional methods and technics (profitability, leverage, break-even), but also modern ones (indicators of value creation, strategic analysis).

Market analyst uses more complex information being demanding on quality. Therefore to eliminate errors from the analysts, the companies provide a permanent direct or indirect quality communication,

through annual analysis of financial statements, intermediate, press releases, interviews and providing information on investment policy, social policy, environmental policy , sector development, etc.

Financial communication is designed to produce information that meets users' expectations. It can be considered an opportunistic communication to generate a reaction from the business partners. In this case we can remember the impact that financial statements have in the day of their public presentation on the market: changes in stock performance, changes in the volume of transactions.

Since the strategies adopted by the shareholders and investors rely on the dualism financial communication - accounting figures, it is easy to understand why presentation modalities and creation of results is a key success factor obscuring true strategic objectives.

5. The report between the financial economical analysis and other management subjects

Management sciences is a set of theoretical practical knowledge on the behavior of organizations. Accounting, management control, audit and business strategy are part of management sciences.

Accounting, as a scientific discipline, locates itself in the science of management today, long after it has been regarded as a discipline of economics category. The new position resulted from the practical role of accounting which became a management instrument of business. Accounting and financial analysis always had a connection area. As we showed in the previous section accounting information is the essential basis of financial analysis.

Management control is defined in the specialty literature as the process by which managers ensure that resources are obtained and used with efficiency, effectiveness and relevance to business objectives. The present race for competitiveness is a challenge to management control that must become a tool for managing organizational performance. Management control has evolved from simple cost analysis based on the budget and then to a real flight deck of the economic

entity. Management control is defined today as a system of pilotage of the company that comes into all the decisional levels from an enterprise, combining information from several subjects. Financial analysis makes a vital contribution through financial variables in control of the company.

In practice diagnostic term is replaced with analysis and **audit**. This phenomenon is due to rise and extend of investigations to which the company is brought. Diagnosis shall not be confused with analysis even if its approach relies on this. The concept of audit has expanded even more as an effect of the trend in the financial economical language, and this is why the speciality literature recommends its use only for the situations in which there are made value judgements through norms, laws, etc (eg. quality audit, accounting audit) [7]. The audit means the professional examination of information in order to express a responsible and independent opinion through reporting to a quality criterion (standard, norm) in order to satisfy the needs of information users. The audit is intended to control financial information with a national utility, for leadership, and an external one for customers, banks, and other categories.

In a firm, audit and control are complementary. Thus, in all its steps, it has a contribution to the control of management control, because internal audit is intended to ensure the quality of information used by the controller. In addition, audit reports provide pertinent information about the appreciation of process functioning from the company in order to elaborate its projects. In turn, in carrying out its duties, the auditor may use by the information to financial analysis to determine weak points. Financial analysis is one of the facets of the audit.

"Enterprise strategy is the art of selecting and optimizing resources and means of any kind that he may have in order to achieve one or more objectives for progress by requiring competition venue, timing and conditions for the competitive struggle" [8]. From this definition we can consider the strategy as important as the production, commercial function, management function, not just as a technical discussion and planning for the enterprise. Financial analysis is a discipline of interpretation using information that must be

treated and handled before being interpreted. The increasing complexity of financial analysis of the company under the extend of competitive economy has profound implications in the process of adopting managerial decision-making which requires the abandonment of routine and use of scientific methods based on reality, in order to establish causal links between economic phenomena and the financial situation of the economic agent, regardless of ownership.

Abstract

Accounting and financial analysis had always a connection zone. Especially in recent years, financial analysis adapted and improved its methods and study processes regarding synthesis accounting documents, which provide database and information required for financial diagnosis, as the main instrument for assessing the financial situation of the company. The theories presented in this paper endorse the affirmation that “the analysis is a particular discipline”. It must be based not only on financial and accounting information, but it must also take into account the environment of the company, and how it is managed. The trends and processes of the economy tend to trivialize the relationship between accounting and financial analysis, by limiting the role of analysis to identifying, collecting, treating and explaining the accounting material.

Key words: accounting, financial analysis, financial statements, accounting information
J.E.L classification: M40.

1. Introduction

The organization must have the ability to adapt to the economic environment and improve its economic and financial performance. Thus, the role of financial analysis is to investigate the economic phenomena and processes, to find causal relationships and factors that generate them. On the basis of these findings, the enterprise decides on future activities.

Financial analysis is an interpretative discipline, which uses information that must be treated and manipulated before being interpreted. The increasing complexity of financial activities, under the expansion of the enterprise competitive economy, has profound implications in the managerial decision-making process, which requires the abandonment of routines and use of scientific methods based on the reality, in order to establish causal connections between economic phenomena and financial statements of the company, regardless the form of ownership.

2. Classic report: financial analysis – accounting

According the Accounting law no. 82/1991, the accounting system applied to Romanian firms is formed by two subsystems: financial accounting and managerial accounting. This structure of accounting system generates a dichotomy. On a hand, financial accounting produces transparent information and, on the other hand, managerial accounting produces confidential information. Between the two disciplines, “managers do not make a clear separation, their treatment often is conjunct, financial accounting needing the information disposed by managerial accounting to establish the results” [1]. The functioning of the enterprise in a competitive environment requires a cost-effective management. This influences the results, as it intervenes in the process of cost analysis that provides to the managers the information necessary for decision making. The information provided by financial accounting is not sufficient for

the calculation of the costs and profitability of a company. In this new accounting system, the synthesis documents serve as tools to inform and develop the financial analysis.

The relationship between financial analysis and accounting focuses on indentifying the accounting as privileged source of information for the financial analysis. Hence, the common concern of specialists is to ensure the quality of information. However, new developments have shown, however, other key connections in the relationship between analysis and accounting, important for both practitioners and researcher. In this paper, we will focus, on highlighting of the relationship between analysis and accounting, emphasizing the connection point, the financial reporting.

Accounting reform in Romania began with the advent of the Accounting Law 82/1991 which targeted and aimed to improve the Romanian accounting system by adhering to principles and rules laid down by European directives, so that financial statements prepared by entities comply with the requirements of certain categories as range of users.

The position, financial performance, and management of any entity (public institutions, economic - commercial, administrative, etc.) necessarily require that their regular work is synthesized and subjected to an analysis of financial statements. As the art.10 of Accounting Law no.82/1991 (republished and modified) states "the official documents used to present the economic-financial situations of legal persons referred to in art.1 (companies, public institutions, associations and organizations, etc.) are annual financial statements, determined by law, which should provide a true financial position, financial performance and other information, related to their activity".

Financial statements are drawn from current accounts, which are audited trough the verification balance, prepared at least annually, or at the time of preparation of periodic financial statements.

Today, the objective of the accounting, according to IASC (International Accounting Standards Committee) can be defined as: "the objective of accounting synthesis documents of an enterprise is to present information regarding financial statements, performance

and evolution of financial statements, to be useful for a wide range of users in order to take financial decisions."

Information regarding financial situation is provided by the balance sheet, information regarding the enterprise's performance in profit and lose account, and information regarding the evolution of financial situation in the cash-flow. Thus, a great importance is given to the summary of accounting documents, known in literature as financial statements.

The rich background of financial statements makes them known as basic tools for managers at all levels. Considering their importance, P.A. Samuel, Nobel laureate in economics, stated "is absolutely important for the modern man to be initiated a little in the accounting items. All those working in the economy should be able to understand the two key surveys, to know the balance sheet and the profit and loss account." [2]

Financial analysis has the responsibility of interpreting and analyzing financial statements. By doing this, the financial analysis provides vital information in the decision-making process to the company's leadership and to other persons interested in this information. Regardless if this information is analyzed by the company's leadership, financial analysts or third parties, the goal of financial analysis remain the same – to provide important, reliable information which facilitates the decision-making process and rational grounds to foresee the future.

Financial statements are a complex of specific accounting summaries, situations, annexes, comparative calculations, also including the management's explanations. They are discussed and approved with signature by authorized bodies, audited and made public. These "formalizations" are meant to enhance the cognitive value of accounting information along with their capitalization in managerial and decisional processes.

The main purpose of financial analysis is to translate and interpret the firm's reality, to serve as the foundation of the resources-allocation decisions. The vision that prevails in the Anglo-Saxon view is the one of the investor, the investment decision. However, in credit-based economies, the financial analysis focuses on the elements of credit

analysis, often followed by specific procedures established at banking level.

One of the approaches is that the financial analysis is part of overall strategic business diagnosis. [1] The approach also touches upon the issue of the source of the information and of the connection with accounting. It analyzes the types of diagnoses and analysis topics, emphasizing the accounting norms relating to the specific analyzed area. The stages of overall diagnoses (economic, financial and strategic diagnosis) can be based on accounting information which is standardized, directly or indirectly by international norms. This brings in question the issue regarding their quality.

We consider that the relationship between financial analysis and accounting must be improved, and we bring as argument the model of financial analysis defined by Cohen: "a set of concepts, methods and tools that cover the accounting information and other managerial information in order to formulate a relative position regarding the financial statements of a company, regarding the risks which affect the entity, the level and the quality of its performance". [3]

3. Actual tendencies of the relationship between accounting and financial analysis

Based on the relationship between the two, we can define the accounting as the main provider of information for financial analysis, and the analysis as a specialized operation and recovery of accounting information.

Financial analysis, "in the acceptance of its basic component of the overall diagnosis, it is targeted towards the investigation of complex issues (global performance of the enterprise, its perennality), ultimately converging with the economic and financial objectives of any economic agent" [2].

We can consider the tendency of financial analysis to find new methods for the diagnosis of the company a normal trend in the current condition of a rapidly changing economy, and in the context of a new accounting system.

The approach cannot exclude the contribution of the accounting, as the information it provides has is irreplaceable in the diagnosis process. Cohen believes that we are dealing with a trend of emancipation of

the financial analysis on its accounting sources in the contemporary economy. According to Cohen, the factors that determine this emancipation are [4]:

- the development of financial markets which leads to the development of the portfolio management tools, based largely on statistical methods of analysis;

- the focus on prospective information in traditional analysis (like credit analysis in economies based on bank financing), which bases its predictions on economic, commercial, political, and social elements.

- economic information providers have a richer offer in today's business environment (financial databases, extra accounting), which relaxes the dependence on analysis of accounting source. The main purpose of financial analysis is to translate and interpret the reality of the firm, and to serve to strengthen the resource allocation decisions.

The studies made by Market Opinion & Research International (MARI), at the request of PricewaterhouseCoopers, regarding the information needed by two categories of user of financial analysis data (employees and investors), shows that companies have as a main purpose improving the result's presentations. Studies aim to encourage the firms to seek ValueReporting and were made for:

- June-July 1997. In this period were interviewed 102 investors and 107 analysts;

- September – October 1997. In this period were interviewed 108 members, managers of large British companies.

According to this study, two problems arise:

- large differences exist between the information needed by the analyst and by the investor. The investor is interested in results and cash-flows;

- there are errors in the information provided, especially for those related to market development, market share, etc.

According to data obtained in the study, the financial statements were satisfactory just for a quarter of those interviewed, the others considering them less useful. In conclusion, the information quality must be improved.

4. Extra accounting information and financial analysis

Accounting information produced by the enterprise, even though it constitutes the essential information for financial analysis, is not its only support. An assessment of the financial statements requires analyzing information both quantitatively and qualitatively. Thus, the financial analyst is forced to use the extra accounting information because accounting information only covers the financial aspects of the enterprise.

Even if is influenced by standardization and normalization, the accounting information is related to the past. We can say that it is not sufficient for making judgments about its future development and the company's performance. Thus, the financial analyst completes its accounting information with extra accounting and non-financial information, from the following sources"

- press releases;
- mass media.

The financial analysis tends to use the extra accounting and non-financial information, because they are more reliable and less standardized.

The main tool of financial analysis is the comparison of information. The reliability of its conclusions is dependent on the quality of information, but also on the experience and interpretation of the financial analyst.

5. Conclusions

Even if the accounting information does not cover the full economic reality of an enterprise, the financial statements remain a reliable source of information. The significance of the accounting information contained in the financial statements also increases when the information is used in the financial analysis.

By exploiting the data from the financial statements, the financial analysis provides the basis of financial information required by all users (internal and external).

The financial analysis can help prepare forecast financial statements, which will allow the assessment of the implementation of the long-term management decisions that may affect the company's financial position and its performance, thus providing a scientific basis for choosing the best strategy.

In order to search for new diagnostic tracks, we consider a normal financial trend analysis. Its approach cannot exclude the contribution of the accounting, information provided by the accounting.

Having an irreplaceable nature in achieving a diagnosis, the trend of the relationship between financial analysis and accounting is in a profound renewal.

The Procedure for the Approval of Activities with Economic and Social Impact on the Environment

Brasoveanu Florica

Lisieviți Brezeanu Alexandru Petru

"Ovidius" University of Constanta, Faculty of Law and Administrative Sciences

floriordache@yahoo.com

Abstract

The problem of pollution and, thus, of environment protection, should be addressed within the broader context of the future economic growth model.

Given that in the environmental protection activity, the emphasis is on preventing unwanted detrimental effects of natural and anthropogenic components of the environment or the environment as a whole, the prior authorization procedure and, prior to it, the obligation to carry out a study on the consequences of human actions on the environment and the possible solutions to be taken in order to reduce or eliminate their effects, are particularly effective legal means for the achievement of sustainable development objectives.

Therefore, impact assessment procedure is a process in accordance with the national environmental legislation, which requires that public and private projects regarding activities with significant environmental impact by their nature, size or location, undergo an assessment process of their effects before the issue of an environmental approval.

Key words: Sustainable Development, Environment, Environmental permit, impact

J.E.L. classification: K 32

1. Introduction

In this area, so sensitive to environmental protection assurance and nature conservation, the legal techniques have evolved significantly over time.

Starting from the idea that it is better to prevent environmental damage than to repair the damage already caused, the

environmental impact assessment procedure of economic and social activities (assessment which is at the basis of the authorization and operation of these activities) emerged and asserted itself. The assessment of potential environmental consequences and the development of measures aimed at eliminating or reducing their allowable limits have become mandatory for social and economic activities, so that future generations can enjoy a healthy and clean environment.

2. The Matter Seat

The restructuring of agriculture, the rational use of energy and of industrial production according to the model offered by nature are imperiously necessary in order to meet the imperative for sustainable economic development. In industry, it is necessary to develop processes which efficiently use materials and energy, which take advantage of secondary products and which generate small amounts of waste. In its turn, agriculture will have to be based entirely on free services provided by ecosystems and thus give up to the almost exclusive dependence on man-made substitutes. Finally, in all systems, products and services prices should reflect the environmental costs of their provision (currently, a country's overall national product does not reflect the consumption of forests, wildlife, reservoirs, potable or fresh water reserves and soil or ecosystem services - maintenance of soil fertility, rainfall storage, air filtration and climate regulation - despite the fact that their loss can lead to high costs).

In this context, the regulation on the prevention, reduction and integrated control of pollution in our country, amended by Emergency Ordinance no. 152 of 10 November 2005 concerning integrated

pollution prevention and control, plays an important role (published in the Official Gazette no. 1078 of 30 November 2005, approved with amendments by Law no. 84 of 5 April 2006, published in the Official Gazette no. 327 of 11 April 2006).

The intertwining dependence and completion of elements of different branches of environmental law, administrative law, community law, constitutional law, civil law and criminal law is obvious, highlighting the complexity of the administrative act, be it legal or individual.

The precautionary principles for taking the environmental decision and the principle of preventing ecological risks and damage production (article 3 of the amended Ordinance no. 195 of 2005 on environment protection) are at the basis of the authorization procedure.

As part of the authorization procedure, the assessment of the impact on the environment is a process by means of which it is identified, described and set, according to each case and in accordance with the law in force, the direct and indirect synergistic, cumulative, main and secondary effects of a project on human and environment health.

If the main cause of ecosphere degradation depends upon the forms of production and consumption of the industrial society, then the solutions must be sought from the perspective of economic positions, but without undersizing the importance of other social, moral, cultural agents and, last but not least, the importance of means offered by positive rights.

An original objective of this procedure lies in its contribution, more or less efficient, to the integration by the public and private decision makers of the environment within their action strategies, in order to avoid the irreparable degradation of the environment by their works and activities. Therefore, this impact study has a twofold purpose, corresponding to the application of two fundamental principles of environmental law:

- the principle of prevention and
- the principle of sustainable development.

The principle of prevention is the oldest of the principles of environmental law. In the face of ecological disaster, and in order to prevent it happening again, States must

provide prior authorization and planning for forecasting activities and formulating programs. But prior planning and automation are not sufficient and safe for taking into consideration the effects of projects upon the environment. Thus, even if those who are responsible think about the consequences of their acts on the environment, the absence of a detailed study would seriously preclude the acknowledgement of environmental requirements.

That is why the impact assessment, as a formal and organized procedure, emerged as an essential element which is necessary in order to ensure that protection becomes a reality and that it does not remain a mere declaration of intent.

Sustainability (development that meets present needs without compromising the ability of future generations to meet them on their own; see Ernest Lupan Dicționar de protecția mediului, Lumina Lex Publishing House, Bucharest, 1997, p. 99) is the most recent of the principles of environmental law. The requirement for the integration of the environment into sectorial policies needs a legal instrument called impact assessment, which has to be applied to both plans and programs and works and activities. The integrated environmental approach can be achieved only through comprehensive institutional approaches, allowing the environment to be represented in all decision-making and administrative structures, and, due to an impact assessment procedure, to be inserted in all decisions affecting the environment. This mixture of the objective of sustainable development and the prevention objective transforms the impact assessment (the main legal instrument of scientific and environmental policies, which basically expresses the requirement that an applicant seeking an environmental permit has to ensure the performance of an impact assessment of the effects of his/her project upon the environment and the possible solutions to reduce or eliminate any inconvenience; Lupan Ernest, op. cit., p. 208) into a very effective instrument of protection proceedings.

The amended Emergency Ordinance no. 195 of 2005 on environmental protection defines the environmental impact assessment as the quantification of the effects of human activity and natural processes on the

environment, health and human safety and on property of any kind.

The impact assessment institution endorses, in principle, the requirement that the person applying for an administrative permit ensures the execution of an assessment of the project impact on the environment and, thus, four main elements are considered:

1 – the analysis of the initial state of the site and its environment (the inventory of what exists);

2 – the assessment of the potential effects due to the impact on the site and on the environment;

3 – social and economic justification; it can be supplemented with additional requirements by special provisions of normative acts.

The environmental impact assessment is a mechanism which allows competent authorities to take a determinant decision. As a specific instrument, the impact assessment fulfills the following purposes:

a) allows the administrative authority which must approve the project to do so knowingly;

b) helps the person in the charge with the work to lead the operation designed in the best conditions;

c) is a study of the consequences that the project may have on the environment.

This procedure is particularly prevalent in all countries, being adequately regulated by national laws and representing the subject of a significant administrative practice.

All States which have environmental regulations quasi-automatically integrate the provisions on impact assessment.

The study refers to the authorization of economic and social activities with an impact upon the environment, including the procedures for establishing environmental obligations with regard to the need of promoting, among administrative authorization acts, clean technologies, the changing of patterns of production and consumption for the sustainable use of materials and energy resources and of reducing the negative impacts on the environment and human health.

The Administrative act becomes an regulatory administrative act (environmental permit, integrated environmental approval/ permit, environmental agreement etc.); it is

issued by the authorized bodies on environmental protection and, for those who are directly/ indirectly interested, and, at this moment, those whom the administrative act is issued are responsible for the compliance with the measures imposed by it; it is also necessary to maintain the cooperation between the issuer and the person who benefits from the act, in order to achieve the desideratum of "A clean Romania".

3. Conclusions

At the end of the study we are bringing a series of legislative suggestions that would be necessary in order to improve and streamline the environmental protection activities in our country:

1. The amendment of Art. 7, paragraph (1) of Government Emergency Ordinance 152/2005 on Integrated pollution prevention and control: although the integrated environmental authorization is issued by Regional Environmental Protection Agencies, its annual authorization (according to the amended Emergency Ordinance no. 195 of 2005) has to be carried out by the County Environmental Protection Agencies, the latter knowing better the conditions and status of the environmental factors on the site of the approved establishment.

2. The establishment of a procedure in case the holder of an activity with environmental impact is changed, because the Government Ordinance no. 195 of 2005 specifies in article 15 that, in this case, the Environment Permit, the Environmental Balance and the Compliance Program that is part of the environmental permit should be revised; the Order MMGA no. 876/2004 on the approval of the authorizing procedure of the activities within an impact upon the environment, mentioned in article 23 that the environmental permit is transferred to the new owner, without incurring the environmental revision provided for in the law for environmental protection.

3. Although it is desired to simplify the procedure for issuing environmental agreements for investments affecting the environment, the terms provided for in MAPM Order no. 860/2002 on approving the Procedure for environmental impact assessment and for issuing the environmental agreement, cause the procedure for issuing

them last, in the best case, around 3 months from the date of the application submission to the Environmental Protection Agency.

The Accountant Instrumentation of the Tangible Fixed Assets for the Companies in the Construction Field

Breuer Adela
Lesconi Frumușanu Mihaela
Jurchescu Dorel
"Eftimie Murgu" University Reșița
West University of Timișoara
a.breuer@uem.ro

Abstract

The paper approaches the problems of tangible fixed assets. We consider pertinent such a research, even if the accountancy of tangible fixed assets in the constructions field does not differ from their accountancy for other firms with different activity field, in the case of firms in the constructions field we encounter tangible fixed assets specific to this entity, such as scaffold and falsework and also documents found in the accountancy of these firms such as the sheet of the equipment daily activity.

Key words: constructions, tangible fixed assets, scaffold and shuttering, the sheet of activity

J.E.L. classification: M41

1. The notion of tangible fixed assets in the specialised literature

In the European perspective, the International Standard of Accountancy IAS 16 „Corporal assets” [6], which describes the accountant treatment applicable to tangible fixed assets and defines them as being those assets which are owned by a company in order to be used in the production of goods or the service in order to be rented to third parties or in order to be used for administrative purposes and it is possible to be used in several periods.

The generic term of tangible fixed assets (also called tangible assets) is used in order to generally identify those assets especially used in the production activity from which the company will benefit on a longer period than 1 year. The term „corporal” or

„tangible” makes the difference from non-corporal assets which are assets without a physical substance or whose value cannot be entirely indicated by their physical existence.

There are authors who define the immobilised assets from the investment point of view, the different aspects of immobilized assets being treated in the economic literature especially separately, on sub-categories of immobilised assets, or from only one point of view, either the accounting or the legal one, that is why we consider that such a paper is useful, because it combines all the aspects, representing a complete guide for the investor [1].

The normalization of the accounting aspects regarding the tangible fixed assets was achieved by the international organization which normalizes the accounting information, beside IAS 16 „Corporal assets” and in the framework of other standards:

- IAS 23 „The loan costs”, the costs components;
- IAS 39 „Financial instruments, recognition and evaluation”;
- IAS36 „The assets depreciation”;
- IFRS5 „Immobilised assets owned for sale and interrupted activities”;
- IAS17 „Leasing Contracts”;
- IFRS5 „Non-current assets owned with the purpose of transaction and activities abandonment.

A problem connected to the tangible fixed assets and which must be analysed is related to the real estate investments. Thus, IAS 40 „real estate investments” defines the real estate investment as being that real estate property (a land or building or part of a building – or both of them) owned (by the

owner or the lodger on the basis of a contract of financial leasing) rather with the purpose of renting or for the increase of the capital value or both of them, than to be sold during the normal course of activity [6]. Nevertheless, IAS 16 „tangible fixed assets” excludes from its application area the real estate investments, highlighting that these real estate investments could be treated according to IAS 16 only if the cost based model is applied, meaning that after the admission as asset, an element of tangible fixed assets must be accounted at its cost minus any accumulated amortization and any losses accumulated from depreciation.

In the continental perspective regarding evaluation, it is considered that in order to be recognized, the asset must be able to be assessed. The input of tangible fixed assets in a company can be done by several possibilities: classical acquisition, own production, leasing contracts, valorisation, exchange with other assets, share to the social capital or donation. The most frequent way of tangible fixed assets input is acquisition; in this case the cost is the value of the respective good which is registered in accountancy (IAS 16 „an element of the tangible fixed assets which is recognised as asset must be initially measured at its cost”).

In the British perspective, in the case of tangible fixed assets, it must be highlighted that the ownership criterion is not retained in order to define them, these containing owned goods (used) by the companies (lodger) in the location-financing contracts, the following are included in this category: land and buildings, plant and machinery, fixtures, fittings and equipment, payments on account and assets in course of construction.

In the British perspective, important stipulations regarding the evaluation of the assets and not only, can be found in the Companies law (CA 85) where the historical cost is retained as main evaluation method.

The tangible fixed assets, as a general rule, are accounted at the historical prize but the British companies can account them at their real value, only the lands are usually registered at their real value because the buildings must be amortized at their accounting value. Concerning the lands and buildings, there is a difference between „freehold property” and „leasehold property”. The first category of buildings

(built on the owned lands) is amortized on the service time of 40-50 years.

For the other tangible fixed assets (cars, fittings, plant, means of transport), the amortization calculated on the economic service time, the period applied to the difference between the acquisition cost and the residual value, the most frequent amortization method is the linear method.

In the American accountancy, there is no norm specifically dedicated to the accountancy of these category of assets, notions regarding the tangible fixed assets can be met in several texts. By analysing these texts, we can observe the different conception towards the notion of real estate heritage, if in the French system, the concept of heritage is based on the legal property of goods, in the American system, it is based on the concept of economic control, which makes the goods which came in by a location-financing contract to be part of the fixed assets.

Regarding the evaluation of tangible fixed assets, in the American perspective, the basic rule is that the assets are assessed at the acquisition cost. The self-cost (the production cost) of the tangible fixed assets developed by the company or the retained expenses having in view their maintenance must be estimated according to the income they generate. The methods used for the cost determination are: the acquisition cost, the right value, the actual value of the expenses retained for the acquisition of the tangible fixed assets and the right value of the goods offered in exchange of the received assets.

We must assign certain aspects connected to tangible fixed assets and the fact that all the expenses retained on the occasion of their entrance, putting into service of the asset are incorporated in their cost and its evaluation is achieved at the historical cost. The demolition and arrangement costs of the land bought for the execution of buildings are part of the land cost; the lands are not the object of amortization.

2. The definition of the tangible fixed assets in the national legislation

The national legislation in force [5] envisaged the same definition of tangible fixed assets, adding a supplementary condition, so that an asset is recognized

as tangible fixed asset, it should have an input value higher than the limit predicted by the law (at present the minimal limit is 1800 lei).

According to the accountant regulations applicable in Romania [7], the tangible fixed assets include:

- land and land organisation;
- buildings;
- technical equipments, means of transport, animals and plantations;
- Furniture, office automation, equipment protecting the human and material values and other fixed assets.

The most used category of tangible fixed assets in the case of construction companies being that of technical installations and means of transport.

Because the main basic requisites so that an asset should be recognized, it should generate some future benefits and be owned by the company, we endorse to the opinion of IAS 40 that the recognition of the assets investment owned by the company and which are generators of income should be recognized as assets.

A tangible fixed asset recognized as asset, according to the legislation in force, must be initially assessed at its determinant cost according to the legislation in force, in terms of the acquirement form [7]:

- for the acquired tangible fixed assets, the initial evaluation is done at the acquisition cost;
- in the case when they are obtained by production, the assets will be registered at production cost;
- in the case of those brought as capital share, the registration is achieved at the share value;
- For the assets received for free, the registration is achieved at right value.

The evaluation of the tangible fixed assets, according to the legislation in force, is achieved on the following moments:

- On the moment of the recognition suspension, meaning at the date of getting out of the heritage, the evaluation of assets is achieved at input value, which is equivalent to their subtraction from inventory. The moment of the recognition suspension comes when an asset is completely amortized and it is taken out by cassation or in the moment of its sale.

- On the occasion of stock-taking, the assets evaluation is performed at actual value, also called inventory value.
- On the moment of closing the exercise, the evaluation is performed at heritage input value, namely, the accountant value which is in accordance with the inventory value.

3. Peculiarities concerning the tangible fixed assets in the construction field

The construction units generally assess the tangible fixed assets entered in inventory at acquisition cost and very rarely at share value or production cost.

The acquisition cost is applied in the case of tangible fixed assets acquired from suppliers by onerous title and it is equal to the purchase price, to which we add the customs taxes, the irredeemable taxes and the other expenses directly connected to the start up of these ones (transport, storage, handling, mounting expenses and other necessary accessory expenses for their start-up at optimal parameters).

The tangible fixed assets used in the production process are specific to the developed activity:

- Machines and equipment for digging and preparation of the ground, which have a normal service time between 4 and 8 years;
- Bulldozers, ditch and cavities diggers with a useful duration of service time between 4 and 8 years;
- Excavators under 150KW have a normal exploitation period between 4 and 8 years and those over 150KW between 6 and 10 years;
- Machines and equipment for infrastructure have an amortization period between 4 and 8 years, except the compressed-air hammers which are amortized on a period between 2 and 4 years;
- Pan mixers and pug mills are amortized in a period between 2 and 4 years;
- Machines, equipment and installations for stonework, coating, finish, casing have a normal service time of 4 to 8 years, an exception being the portable mechanical tools (electric, pneumatic and hydraulic) which are amortized in 2-4 years.

The analytic accountancy of machines, installations, apparatus and control means is performed in the same way as for the other companies in the asset sheet. Specific for the construction companies is that by the end of each month, you should attach at the sheet of each equipment or installation an „Operation report” in which there are presented according to the type of tangible fixed asset, the following:

- for the machines and equipment for digging and preparation of the ground, the number of active hours operation with the specification of the number of loads-unloads every day, the number of break hours of these ones and the stipulation if the break was a normal one or from other reasons;
- for bulldozers the number of operation hours and the number of kilometres;
- for excavator, the number of operation hours and the number of rotations for load-unload;
- pentru rabe, bascule și alte mijloace de transport similare, se specifică atât numărul de ore de funcționare, numărul de basculări cât kilometrii parcurși.
- For trucks, weighing machines and other similar transport means, it should be specified both the number of operation hours and the number of overturning and the kilometres covered.
- For all the others, the number of operation hours.

For all these, there is the daily activity sheet (DAS) drawn by the manipulator of the equipment or machine, it is approved by the end of the day by the technician of the equipment park. Likewise, he registers on each DAS the number of litres and the type of the used fuel, the number of litres of engine and gearbox oil, the completed brake fluid, he also calculates the real consumption for each transport means separately, the number of break hours and the reasons of the break, if there were any repairs and what parts were used.

Besides the tangible fixed assets common to other branches of the national economy, in the category „technological equipments”, in the case of the construction field, we also encounter a specific category of this one, shuttering and scaffolds. Even if by their denomination, they send our thought to the

constructing elements which are used only once, then we do not use them, these elements specific to the construction activities are not consumed at their first use: the carpenter shuttering and scaffolds are made of wood which will be used at least 3 or 4 times, the scale boards are used 20-30 times until they must be replaced, the sliding formwork can be used up to 100 times [2].

The formwork is a wooden or metallic pattern in which a material is poured in its fluid shape in order to harden in the desired form. The use of formworks leads to the execution of two processes specific to constructions:

- Concrete forming supposes the mounting of formworks during the execution works of the monolith concrete;
- Striking is the operation of removing the formworks after the concrete hardened and got the desired form and resistance.

Among the tangible fixed assets, there are the following formworks types:

- Sliding formworks are used at the execution of steel concrete or prestressed walls or for the mixed masonry and it results from the combination of wooden or metallic formworks and metallic frames, hydraulic pumps and lifting gear.
- Pneumatic formworks are used for the construction of sewage pipes;
- Planar metallic formworks are made of metallic panels with big plan surfaces;

The scaffold is an auxiliary temporary construction made of wood or metal, serving as support for equipment or workers who work at height. In the category of tangible fixed assets there are the following scaffold types:

- Exterior fixed scaffolds used for the execution of high exterior facades for plastering, paintings and other operations;
- Self-lifting scaffolds which are electrically operated.

According to the data centralised from the construction companies we have analysed, this category of tangible fixed assets are included, according to the Catalogue concerning the classification and normal service time of the assets in the category „equipment, devices and instruments used in constructions” (classification code 2.1.20),and they have normal service time between 2 and 4 years [5].

Brands and Brand Equity

Brunello Adrian

adrian_brunello@yahoo.com

Abstract

Nowadays brands have become significant drivers for product purchasing and usage decisions. Thus, they constitute a substantial intangible asset for most companies. In order to gain customers and make them become loyal, firms have to establish the equity of the brand and present it in a clear and visible way to their target market. Therefore the topic of brand equity plays a major role in the creation and development of product and company brand strategy. The paper focuses on some general information about the brand and discusses the two stages of defining the brand, where one can find new elements that lead to brand equity. The purpose of this article is to present the main issues pertaining to brand equity and to analyze the customer-oriented and the market performance-oriented perspectives of brand equity.

Key words: brands, brand equity, marketing perspective, financial accounting perspective.

J.E.L. classification: M310

1. From products to brands; from identity to differentiation

It is important to contrast a brand with a product. A product is anything that can be offered to a market for attention, acquisition, use or consumption that might satisfy a need or want. Thus, a product may be a physical item, service, a shop, person, organization, place or idea. The brand, on the other hand, is a product that adds some dimensions that differentiate it in some way from other products designed to satisfy the same need. These differences can be rational or tangible – related to product performance of the brand or more symbolic, emotional and intangible – related to what the brand represents.

There are two important stages in defining the brand. The first one refers to its function as an identifier while the second one introduces new elements which lead to the concept of brand equity.

The American Marketing Association (AMA) defines the brand as "a name, term, sign, symbol, or design, or a combination of them, intended to identify the goods and services of one seller or group of sellers and to differentiate them from those of competitors". Within this view, as Keller (2003) says, "technically speaking whenever a marketer creates a new name, logo, or symbol for a new product, he or she has created a brand". He recognizes, however, that brands today are much more than that. As can be seen, according to these definitions brands had a simple and clear function as identifiers.

The second stage deals with concepts such brand loyalty or brand image. Brand loyalty is the result of the brand's presentation of a level of quality which makes the satisfied customers to repurchase the product. Loyalty offers anticipation and prevents other companies from entering the market.

Kapferer (1997) mentioned that "the brand is a sign - therefore external - whose function is to disclose the hidden qualities of the product which are inaccessible to contact". The brand initially served to identify a product and to distinguish it from the competition. The shift in focus towards brands began when it was understood that they were something more than mere identifiers. Brands, according to Kapferer, serve eight functions: the first two are mechanical and concern the essence of the brand: "to function as a recognized symbol in order to facilitate choice and to gain time"; the next three are for reducing the perceived risk; and the final three concern the pleasure side of a brand. He adds that brands perform an economic function in the mind of the consumer, "the value of the brand comes

from its ability to gain an exclusive, positive and prominent meaning in the minds of a large number of consumers". Therefore branding and brand building should focus on developing brand value.

The Functions of the Brand for the consumers are [2]:

- Identification – to be clearly seen, to make sense of the offer, to quickly identify the sought-after products.
- Practicability –to allow savings of time and energy through identical repurchasing and loyalty.
- Guarantee –to be sure of finding the same quality no matter where or when you buy the product or service.
- Optimization - to be sure of buying the best product in its category, the best performer for a particular purpose.
- Characterization - to have confirmation of your self-image or the image that you present to others.
- Continuity - Satisfaction brought about through familiarity and intimacy with the brand that you have been consuming for years.
- Hedonistic - Satisfaction linked to the attractiveness of the brand, to its logo, to its communication.
- Ethical - Satisfaction linked to the responsible behavior of the brand in its relationship towards society.

2. Brand Equity

An emerging debate started to address whether brand equity should be analyzed from a consumer-oriented or a market performance-oriented perspective. Motomeni and Shahrokhi (1998) presented this disagreement and they identified two opposing viewpoints: the marketing perspective and the financial accounting perspective.

There have been two general motivations for studying brand equity. One is financially based motivation to estimate the value of a brand more precisely for accounting purposes - in terms of asset valuation for the balance sheet or for merger, acquisition or divestiture purposes. A second reason for studying brand equity arises from a strategy-based motivation to improve marketing productivity. Given higher costs, greater

competition, and flattening demand in many markets, firms seek to increase the efficiency of their marketing expenses.

As a consequence, marketers need a more thorough understanding of consumer behavior as a basis for making better strategic decisions about target market definition and product positioning. Perhaps one of the firm's most valuable assets for improving marketing productivity is the knowledge that has been created about the brand in consumers' minds from the firm's investment in previous marketing programs. Financial valuation issues have little relevance if no underlying value for the brand has been created or if managers do not know how to exploit that value by developing profitable brand strategies. [1]

The practice of branding has been conducted for centuries as a means for producers to distinguish their goods against those of competitors by creating a recognizable and memorable image. Farquhar (1989) states "A brand is a name, symbol, design, or mark that enhances the value of a product beyond its functional purpose". The term brand equity first came into wide spread use in the 1980s and was defined as "The „added value" with which a brand endows a product." [4]. This definition, served as the springboard of future research.

Aaker defined brand equity as "a set of five categories of brand assets (liabilities) linked to a brand's name or symbol that add to (subtract from) the value provided by a product or service". He presented in his model the five dimensions of brand equity: a) brand awareness; b) brand perceived quality; c) brand associations; d) brand loyalty; and e) other proprietary brand assets, such as patents, trademarks and channel relationships. Aaker considers these dimensions the main bases for brand equity measurement. This conceptualization focuses only on the consumer oriented perspective and does not take brand market performance into account.

One of the first critical articles of brand equity Feldwick (1996) finds that the term brand equity has three different meanings depending on the instance of use. At any one time brand equity can be used to refer to brand description (consumer associations with the brand name), brand strength (similar

to Aaker as a measure of relative consumer demand for the brand), and brand value (to set a price of the brand for when it is sold). Feldwick argues that brand equity is a vague concept especially due to its lack of measurability and application in the business environment.

As Feldwick was contending against brand equity, Kotler et al. (1996) were supporting the conclusions of Farquhar and Aaker by defining brand equity as "The value of a brand, based on the extent to which it has high brand loyalty, name awareness, perceived quality, strong brand associations, and other assets such as patents, trademarks, and channel relationships." Kotler did not directly counter the assertions of Feldwick, but gave a highly credible voice to the validity of the topic subject.

Aaker's subsequent work (1996) added to his earlier findings, making the model more encompassing of different markets with modifications based on updated research. This debate continued as Ehrenberg (1997) built upon earlier arguments against brand equity by reasserting the lack of tangibility and clear definition of the concept. He argued that high brand equity is due to large sales and a sizeable advertising budget, since consumers are more likely to favor the larger brand names. However, Baldinger and Rubinson (1997) argued against the assertions of Ehrenberg by showing research that customer attitudes can be measured with some level of validity and that brands (large or small) do show a decrease in strength when observed over a long period of time.

Other authors have also tried to provide some insight and credence to the field of branding and brand equity by reducing the ambiguity in the term and misinterpretation regarding the use of similar terms. Faircloth, Capella and Alford (2001) developed a stage model that shows the attitude consumer's form regarding a brand leads to the image the brand takes in their mind. Brand attitude does not fully explain brand equity, but rather contributes to the framing of a brand image, which will lead to positive or negative brand equity. Moving from one stage to the next does not involve a full transfer of beliefs and feelings, but rather they lead to the full development of a brand in the mind of the consumers.

Winters (1991) connected brand equity to added value and suggested that brand equity involves the value added to a product by consumers' associations and perceptions of a particular brand name. Aaker (2004) also stated that brands "provide value to the customer by enhancing interpretation and information processing, confidence in decision making, and use satisfaction; and provide value to the firm by enhancing efficiency and effectiveness of marketing programs, brand loyalty, prices and margins, brand extensions, trade leverage, and possessing a competitive advantage. Such conceptualization shows that the brands offer value both to customers and to companies.

Simon and Sullivan (1993) defined brand equity as "the incremental discounted cash flows that would result from a product having its brand name in comparison with the proceeds that would accrue if the same product did not have that brand name". Their conceptualization is based on a financial accounting perspective, considering brand market performance, without emphasizing consumers' attitudes towards the brands. The financial based methods use estimation techniques to determine the incremental cash flows which accrue to the firm through their branded products.

The ones who are in favor of the financial accounting perspective argue that it incorporates both macro and micro approaches. The macro approach assigns an objective value to a company's brand and related this value to the determinants of brand equity, while the micro approach isolates changes in brand equity at the individual brand level by measuring the response of brand equity to marketing activities. Therefore, they consider that the financial markets do not ignore marketing factors, and stock prices should reflect marketing decisions. [3]

The literature review reveals further that brand equity provides value for both the customer and the firm. Brand equity creates value to customers by enhancing efficient information processing and shopping, building confidence in decision making, reinforcing buying, and contributing to self-esteem. Brand equity creates value to firms by increasing marketing efficiency and effectiveness, building brand loyalty, improving profit margins, gaining leverage

over retailers, and achieving distinctiveness over the competition.

Brand equity offers certain strategic benefits to companies. It is important for adding line extension. When a product category has entered the decline stage of the product life cycle, strong brand equity can help a brand survive longer than its competitors. Likewise, in periods of economic downturn, brand equity provides a platform that keeps the brand afloat at a profit long after competing products without strong brand identification begin to flounder. The power of brand equity is especially important in international marketing. Global brands have international presence and visibility, and this "equity" makes it easier for them to expand. Brand equity is also what enables branded products or services to charge premium prices. Many major brands are positioned as quality products, and many people are willing to pay more for a quality product they are familiar with, particularly if the brand has an image with which they would like to be associated. The challenge is to find the point where the premium price is still acceptable in exchange for the confidence embedded in the brand. [12]

In conclusion one could state that brand equity helps to differentiate the product from competitors' offerings; serves as a proxy for quality and creates positive images in consumers' minds; presents market share erosion during price and promotional wars; and prevents market share erosion by giving a firm time to respond to competitive threats.

3. Customer-based brand equity

The basic premise with customer-based brand equity is that the power of a brand lies in the minds of consumers and what they have experienced and learned about the brand over time. The advantage of conceptualising brand equity from the consumer's perspective is that it enables managers to consider specifically how their marketing program improves the value of their brands. Though the eventual goal of many marketing programs is to increase sales, it is first necessary to establish knowledge structures for the brand so that consumers respond favorably to the marketing activity of the brand. [1]

Keller defined "Customer-Based Brand Equity" as "the differential effect of brand knowledge on consumer response to the marketing of the brand". There are three key ingredients to this definition: 1) differential effect, 2) brand knowledge, and 3) consumer response to marketing. First, brand equity arises from differences in consumer response. If no differences occur, then the brand can essentially be classified as a commodity or generic version of the product. Second, these differences in response are a result of consumers' knowledge about the brand. Thus, although strongly influenced by the marketing activity of the firm, brand equity ultimately depends on what resides in the minds of consumers. Third, the differential response by consumers that makes up the brand equity is reflected in perceptions, preferences, and behavior related to all aspects of the marketing of a brand [1].

Further, Keller identified streams of research that attempted to formally conceptualise brand equity: a) psychology-based approaches; b) economics-based approaches and socio-cultural approaches. The first type adopts associative network memory models, where a given brand is depicted as a node surrounded by different associations. The Economic-based approaches centered on the role of credibility as primary determinant of Customer-Based Brand Equity. It is argued that brand reduce consumers' uncertainty by lowering information costs and perceived risks. Socio-cultural-based approaches refer to elements such as brand communities and brand relationships [1].

Conceptualising brand equity from the consumer's perspective is useful because it suggests both specific guidelines for marketing strategies and tactics and areas where research can be useful in assisting managerial decision making. Two important points emerge from this conceptualisation. First, marketers should take a broad view of marketing activity for a brand and recognise the various effects it has on brand knowledge, as well as how changes in brand knowledge affect more traditional outcome measures such as sales. Second, markets must realise that the long-term success of all future marketing programs for a brand is greatly affected by the knowledge about the brand in memory that has been established by

the firm's short term marketing efforts. In short, because the content and structure of memory for the brand will influence the effectiveness of future brand strategies, it is critical that managers understand how their marketing programs affect consumer learning and thus subsequent recall for brand-related information [1].

A brand is said to have positive (negative) customer-based brand equity when consumers react more (less) favorably to a product and the way it is marketed when the brand is identified as compared to when it is not. Thus, a brand with positive customer-based brand equity might result in consumers being more accepting of a new brand extension, less sensitive to price increases and withdrawal of advertising support, or more willing to seek the brand in a new distribution channel. Customer-based brand equity occurs when the consumer is familiar with the brand and holds some positive brand associations in memory. Favorable consumer response, in turn, can lead to enhanced revenues, lower costs, and greater profits for the firm [1].

Brand knowledge is the key issue in creating customer-based brand equity. Brand knowledge can be conceptualised as consisting of a brand node in memory with a variety of brand associations. Brand knowledge is composed of 1) brand awareness, which relates to consumers' ability to recognise or recall the brand and 2) brand image, which consists of consumers' perceptions of and associations for the brand. Building brand awareness requires repeatedly exposing consumers to the brand as well as linking the brand in consumer memory to its product category and to purchase, usage and consumption situations. Creating a positive brand image requires establishing strong, favorable and unique associations for the brand.

Brand awareness is related to the strength of the brand node in memory, as reflected by consumers' ability to identify the brand under different conditions. Brand awareness consists of 1) brand recognition reflecting the ability of consumers to confirm prior exposure to the brand and 2) brand recall reflecting the ability of consumers to retrieve the brand, when given the product category, the needs fulfilled by the category, or some other type probe as a cue. Brand awareness

can be characterised according to depth and breadth. The depth of brand awareness concerns the likelihood that the brand can be recognised or recalled and the breadth of brand awareness relates to the variety of purchase and consumption situations in which the brand comes to mind [1].

Brand image is defined as consumer perceptions of a brand as reflected by the brand associations held in consumers' memory. Brand associations are informational nodes linked to the brand node in memory and contain the meaning of the brand for consumers. Brand associations come in many different types, which include e.g., product-related and non-product related attributes, functional, symbolic or experiential benefits and attitudes. For customer based brand equity to occur, some of these brand associations must be strong, favorable, and unique. Strong associations are likely to result with information deemed relevant and presented consistently over time. Favorable brand associations occur when consumers believe that the brand possesses attributes and benefits that satisfy their needs and wants. In terms of uniqueness brand associations may or may not be shared with other competing brands. The strength, favorability, and uniqueness of brand associations play an important role in determining the differential response that makes up customer-based brand equity, especially in high involvement decision settings where consumer motivation and ability are sufficiently present (Keller 2003). Brand image is the sum of impressions that affect how we perceive a brand, including elements that identify or distinguish the brand from others, the personality the brand acquires, and the benefits it promises. Brand image is largely a subjective and perceptual phenomenon that is formed through consumer interpretation, whether reasoned or emotional. When brand images are strong, they can be used to enhance a person's self-image [12].

4. Conclusions

Brand equity can be regarded as a managerial concept, as a financial intangible asset, as a relationship concept or as a customer-based concept from the perspective of the individual consumer.

In a general sense, brand equity is defined in terms of the marketing effects uniquely attributable to the brand. That is, brand equity relates to the fact that different outcomes result from the marketing of a product or service because of its brand element, as compared to outcomes if that same product or service did not have that brand identification.

The main asset dimensions of brand equity can be grouped into brand loyalty, brand awareness, perceived quality and brand associations.

Brand equity can be built by creating positive brand evaluations with a quality product, by fostering accessible brand attitudes to have the most impact on consumer purchase behavior, and by developing a consistent brand image to form a relationship with the consumer.

Brand equity can create advantages and benefits for the firm, the trade or the consumer. From the firm's perspective brand equity imparts competitive advantages to the firm.

Brand equity from an individual consumer's perspective is reflected by the increase in the strength of associations an individual has for a product by using the brand. Successful branding means lower uncertainty in purchasing. There is also less need for an extensive decision making process on the part of the customer. Brands carry with them certain assurances of product quality and reliability in use. Product identification in large, cluttered supermarkets, department stores or mass merchandising outlets is facilitated. There are also psychological benefits to the customer using brands.

Aspects of Social Policy in Romania in the Context of E.U. Integration

Bucur Ion

ionbucur2006@yahoo.com

Abstract

The social policy is an ensemble of public policies pursuing the accomplishment of social protection and wealth. In Romania, the social protection strategy targets the following directions: protecting the employee through an appropriate legislation; protecting the disadvantaged social groups; satisfying collective necessities (education, health, culture, etc.); protecting the population against pathological social processes (alcoholism, drug consume, etc.).

An important role in the social protection has the social security. It's a system formed from elements used to ensure the existence of resources necessary for people that are confronted with social risks like unemployment, sickness, old age, insufficient or no income and supporting families with more than one child. These resources can be cash benefits in form of aids (allocations, indemnities, pension), free goods or with partial payment, reductions or exemptions from taxes. The Romanian security system is characterized through insufficient resources necessary to ensure the existence of some categories of poor citizens.

Key words: poverty, social protection, social security, social policy

J.E.L. classification: F15

1. Poverty – definition and implications on the economic growth

Poverty represents a state that encompasses the individual or the group he is a part of (family), characterized through the lack of intellectual capacity and a minimum of economic resources needed to satisfy the basic needs and the survival in a society. It

implies inadequate basic life conditions and economic resources that will allow the individual to have at least minimal participation in the social life.

Poverty usually means the lack of financial resources that could assure the human individual a standard of living fit to the collectivity's standards [1].

Poverty can also be understood as an absolute phenomenon or a relative one [2]. Absolute poverty means the absence of the minimum conditions that will allow to the individual and his family to survive as the society requires. Relative poverty means the absence of the minimum resources required for an individual (family) to normally function in a given socially-cultural context.

The phenomenon of poverty is met in all the world's countries, without being compared to a certain standard of poverty.

Therefore, the standard of poverty in a rich country is different from the one of a poor country and the percentage of poor people in the total of the population differs in developed countries compared to poorly developed ones.

Poverty is an unstable phenomenon that can be present or can disappear from a person's life according to the support offered by the state and the use of his intellect and creativity to find new ways that will ensure him the conditions necessary in order to live a decent life, as well as his family.

The factors that contribute to surpassing or avoiding poverty of a person are the education he receives, the level of socialization of the group he is a part of and the living standards of the collectivity he is living in. Family is another important factor that can remove the individual from poverty through the model of life it offers, the support given for his preparation for life and a certain profession.

In the same time, the individual has reduces opportunities to avoid poverty when his family does not offer a proper environment for his development and harnessing his own potential when it gives wrong life models, that do not contribute to the development of winner mentality.

The extension of poverty represents a restrictive factor of the economic growth and the revival of economic and social development [3].

2. Preventing expansion and poverty reduction ratios - the heart of social policy

Another severe phenomenon that the Romanian society is facing at the beginning of the third millennium is the growth of poverty.

The diminishment of poverty is a basic objective of the social policy. In our country, the social policy currently targets the protection of the population against the negative effects of the economical crisis. The social protection strategy follows the following directions:

- protecting the employees trough an appropriate legislation;
- protection for the disadvantaged social groups: unemployed, families with more than one child, old people, orphans, handicapped, etc.
- satisfying some collective necessities: education, health, culture, sport, etc.
- protecting the population against some pathological social processes: alcoholism, drug abuse, criminality, etc.

This kind of social measures is taken to ensure the economic freedom and the fundamental human rights.

Usually the social protection offered by the social policy is focused on health spending, unemployment benefits, aid for disadvantaged people, etc.

In the total of the means of social protection, an important role has the social security [4]. In a modern economy, the social security contributes to the attenuation of the effects of poverty trough assuring some social income for individuals that couldn't obtain incomes from work anymore due to social risks (old age, sickness, unemployment), as well as to families with

many children that do not meet the social requirements.

The social security consists of a system based on an aggregate of elements made to ensure resources necessary for the existence of people facing social risks like unemployment, sickness, the lack or insufficient incomes and to support families with more than one child.

The offered resources can be:

- cash benefits like aids, allocations, indemnities, pensions;
- free goods or with partial payment, reductions or exemptions from taxes.

The cash benefits are direct incomes used for various costs, costs of current or occasional consume. Benefits in kind and exemptions from taxes are indirect incomes because they shield the families from various expenses like paying for medical services, obtaining free medicine or partially paid, etc.

The Romanian social security system is complicated and contains different protection schematics for the same social risk and institutions that have the same attributions and responsibilities.

It is characterized trough insufficient resources necessary to ensure the existence of some categories of poor individuals. In terms of the massive restraining of occupation and economic recession the number of people that need social protection has grown. The restraining of occupation has caused the growth of the number of retired people, mostly because of early retirement, aiming to ease labor market. The number of retired people with social insurances (without farmers) has grown from 2.2 millions in 1989 to over 4.7807 millions in October 2010 [5].

Under these conditions, the relation between unemployed + pensioners and wage-earners is burdensome for wage-earners and the economical units.

Reducing the number of wage-earners and increasing the number of people that need to benefit from social aids has created and amplified the tasks that the wage-earners and economic agents must do. As a response, the costs and prices had grown too, the increase of salaries was restricted, the underground work market was encouraged and the real value of social insurances has dropped.

The budget expenditures have also grown trough payment of pensions for the old agricultural pensioners from budgetary

sources. The adopted solution is correct because the peasants had contributed with working force and important financial resources to the development of the Romanian economy during the years of centralized government. Therefore, it wouldn't have been fair that the payment of the peasant pensions to depend on the resources of the current farms and agriculture in development. The number of agricultural pensioners has grown from 1.6 millions in 1996 to 7.181 millions in October 2010 [7].

The social security coverage has extended through the development of social protection schemes, through instituting a social aid and by increasing the number of handicapped people and politically persecuted individuals. The number of handicapped people has grown from 80.000 in 1992 to 670.000 in 2009 [8].

The extension of the social security coverage constitutes a major restriction that disallows the social security system to contribute in a greater fashion to the fight against poverty.

Another major restriction is the reduced percentage of the public expenditures in the GDP. If the developed countries invest more than 30% of the GDP in the social policies, Romania invests less than half of the EU average: 16,41%, less than all the European countries that had recently passed through transitions and are currently EU members [9]. Reducing the budgetary resources and implicitly the resources needed for social security has as a main cause the decrease of the macroeconomic incomes. Also, the main factor to fight poverty is the recovery of the economic activity and the resuming of the economical growth. Another restriction that diminishes the capacity of the social security to fight against poverty is the necessity of a correlation between the incomes from social benefits and those from work, as well as those between the social assistance benefits and the ones from social security. To determine a fair behavior towards work, the social benefits must be lower than the wages.

The social security efficiently contributes to combating poverty when the incomes of the majority are above the poverty threshold. The possibilities of combating poverty grow by increasing the economic activity and the general level of incomes. A better usage of the available resources implies to direct them

towards the categories of population and families that need them more in order to be protected against poverty.

3. Lines of action to alleviate poverty

The alleviation of poverty implies objectives, actions and social policies strategies analyzed at the level of EU and each state.

The extension of unemployment and the lower purchasing power determines lower living standards. Decreasing the incomes as one of the measures against the crisis diminishes the consume budget of a great part of Romania's population. In these conditions expenses won't be possible in order to cover the needs for alimentation, medication and others.

A decisive factor to restrict the extension of poverty is to resume the economic growth and to increase the budgetary revenues. Otherwise, Romania's economy will have the traits of poor countries, with living standards for the majority of the population close to the poverty line.

A less covered subject compared to the economical dimensions tied to the development of a unique market, the liberalization of the capital movements and the creation of the monetary union is EU's social dimension.

An explanation can be that in the first three decades of the post-war period a high level of economic prosperity was recorded of the citizens of the member states, creating the conviction that the economic progress generates social progress. But the positive economical results do not automatically resolve the social problems that the citizens face. Among the social problems that the population of the EU must face are:

- increasing the number of unemployed and a low employment rate;
- large share of structural and long term unemployment;
- high discrepancies of the unemployment rate between countries;
- the need for a reform in the social security system, particularly in the areas of pensions, unemployment benefits, familial allowances, etc.

The Lisbon summit (March 2010) has underlined the necessity of an economic and social reform, in the context of a strategy that

combines competitiveness with social cohesion.

The Lisbon strategy contains directions and measures for the modernization of the work markets and the social protection systems, combating poverty and promoting the equality of chances in order to stimulate prosperity and solidarity in the EU [10].

The main priorities of the EU's social policy are:

- increasing the working force through ways like:

- o increasing the professional mobility
- o increasing the jobs

- combating poverty and promoting the equality of chances, actions that necessitate solving some problems regarding:

- o managing the demographic changes
- o updating the pensions and healthcare
- o analyzing the discrimination of the working factor

In July 2008, the European Committee has elaborated a renewed European agenda that bases on 3 interconnected objectives:

1. Creating opportunities, something that implies the creation of jobs and the facilitation of mobility.

2. Improving the access at education, social protection, medical assistance and better quality services for the citizens of the EU members.

3. Manifesting the solidarity between generations, regions, the rich and the less wealthy, the richer member states and the poorer ones. The solidarity means the act of helping the disadvantaged ones, who cannot benefit from the advantages of a defensive society that finds itself in a rapid change. This means fostering social inclusion, integration and poverty reduction.

The accomplishment of these objectives implies actions for whose realization each member state is responsible, targeting areas like: the youth, the human capital, health and the average life expectation, the mobility of the working factor, social inclusions, equal opportunities and others.

That main factor that contributes to alleviation of poverty is the stimulation of the economic growth and the creation of jobs.

Another factor facilitating the finding and occupation of the working factor is the modernization of the work market. It implies the extension of the employing forms (employing based on flexible and reliable

work contracts), lifelong learning and others. An important role in filling skill shortages plays immigration.

Investments made to develop human capital and education increase the employability of the work factor. In a world found in a perpetual change, human can have access to employing opportunities that arrive in different stages of life if they learn and continually renew their skills.

The geographical mobility of the work factor and the elimination of potential obstacles is contributing to the increase in the occupation degree and stimulates the economic growth.

Increasing the share of elderly in the EU member states requires the enhancement of research regarding the way through which the health and wealth of elderly can be improved and how the public funding required for the accomplishment of these objectives can be acquired. The European strategy regarding health targets the citizen's access to key aspects regarding health and the aid of individuals to remain on the working market for a longer time through the improvement of protection against risks at the working place.

In the EU it is promoted a policy of combating the discrimination in order to assure equal opportunities for the citizens when it comes to the opportunities in employment or other areas of the social-economic life. In this purpose a legislative framework was created, meant to promote the rights of the European citizens as consumers and (or) producers.

A vital contribution to the promotion of opportunities and social cohesion has the partnership between the institutions and European states. Through the collaboration between the institutions from the member states the workers and firms capacity to anticipate the changes can be increased, in order to find the best use for the European funds, to accomplish the objectives of social policy.

In Romania, the social policy was particularly based on promoting active policies regarding the social inclusion in all the areas. At the basis of the inclusion policies lie the principles "ensuring a sufficient income" and "the activation" of people facing the risk of social exclusion.

The social policy includes measures of occupation growth and development of the social services to support people found in vulnerable situations. Their number is higher considering that Romania faces a high rate of unemployment, with an extended poverty, with regional disparities under the aspect of economic and social development, with an aging population.

Among the problems that our country faces are the active inclusion on the work market of the people with disabilities and the development of adequate social services in order to facilitate employment for all the disabled individuals that can and want to work. In this purpose, the professional training of the handicapped persons is needed, as well as creating assisted workshops to employ them.

Exchange Rate - a Tool to Influence Economic Life

Bucur Ion

Dusmanescu Dorel

ionbucur2006@yahoo.com

Abstract

The exchange rate, the price of a national currency against another currency to which we compare values in certain conditions of time and place, has different influencing factors and various effects over the economic life. Among the influencing factors are the evolution of the national currency demand and supply relation, economic, fiscal and politic stability, interest rate, capital movements, the external commerce situation, long term loans, investments made by a country abroad, etc .In Romania, during the transition years, the leu's exchange rate has dropped due to factors like exchanging lei deposits to foreign currency one in fear of interest rate lowering, purchase of foreign currency by importers with part of the sums in lei owned, purchase of foreign currency by the National Bank in order to prevent de fast growth of the exchange rate in terms of declining confidence in lei, etc .

Key words: exchange rate, supply and demand relationship, economic stability, balance of payments

J.E.L. classification: F31

1. Exchange rate – definition and influencing factors

The exchange rate is a variable with various causes and implications on the evolution of an economy. It represents the price of a national currency in relation with another currency with who its value is compared in certain conditions of time and place. The exchange rate approximately shows the parity of the purchasing power and it can appreciate and depreciate on different time intervals. A currency appreciates when

its value increases in relation with other foreign currencies; when its value drops, the currency depreciates.

The exchange rate is influenced by various factors like: the evolution of the currency supply and demand relationships, the economical, political and fiscal stability, inflation, interest rate, capital movements, the situation of the exterior commerce, long term loans, investments made by a country abroad and others.

The extern purchasing value of a currency or the exchange rate is influenced first hand by *the evolution of the supply and demand relationship*. When the demand for a currency increases, the exchange rate grows too and the currency appreciates. The demand for a currency increases when more individuals or entities make investments, exchanging their money with the currency in case.

The political, economical and fiscal stability of a country determines the increase of demand for its currency. Any information that signals instability determines the erosion of the external value of the currency.

In Romania, the leu's exchange rate has depreciated because of the inflation, in the years of transition to a modern market economy. When in a country is registered an inflation rate higher than in the countries with which it has economical relationships, the currency of that country depreciates.

The increase of the unemployment rate and the preservation at a high level of this phenomenon determines a lower exchange rate. In the same way acts the manifestation of a political incertitude in a country or a region.

The interest rate is another important factor that influences the exchange rate, especially for a country with a free convertible currency and with consistent foreign reserves.

The interest rate increase determines the withholding of withdrawal of capital from abroad and the growth of the exchange rate.

The significant capital movements exert a powerful influence over the exchange rate¹. The substantial increase of the foreign capital in a country favors the appreciation of the country's currency. The causes of the capital movements are the evolutions and the expectations regarding the evolutions of a country's exchange rate.

This way, the international merchants are interested to keep their money in deposits that will bring to them interests and have the desire to loan them on the markets where the interest rates are the highest, the other conditions being constants. If, on a short term, the interest rate grows and becomes bigger than in other countries, it will attract capital toward this country or at least deposits in the country's currency. When the interest rates drop and become lower than in other countries, there is a tendency for capital to move from that country.

The high rates of the interests in a country tend to appreciate the currency and the low rates tend to depreciate it.

The demand for a country's currency grows when the currency's appreciation is expected; if the depreciation is to be expected, the demand drops because the individuals and entities will be more reluctant to buy.

Capital movements on a long term are influenced by the expectations regarding the profit opportunities along with the expectations regarding the exchange rate evolution.

The foreign companies are willing to invest in a country if they think they might earn a higher profit than in their own countries.

The exchange rate is also influenced by the status of the *exterior commerce*. When a country imports more than it exports, it registers a deficit in its current account on the financial markets; the deficits of the current account are signs of long term instability. All the other conditions being equal, the countries with current accounts surpluses have a strong currency and the countries with current account deficits have weaker currency.

Increasing the export determines the appreciation of the national currency and the growth of the import determines its depreciation. In order to appreciate the national currency, the economical assets exports must be greater than the imports. Also, the national currency appreciation stimulates the import and the national currency depreciation stimulates the export.

The export volume depends on the exported goods demand elasticity. When the demand is inelastic, the increase of exported goods determines in a lower measure the appreciation of the national currency because the amount of foreign currency entering the country is smaller.

The price growth for the imported goods determines the depreciation of the national currency. When the imported goods have an elastic request, the depreciation is greater because more foreign currency is spent, and when they have an inelastic request, the depreciation is lower.

The role of the commercial trade balance is primordial on the currency market; a chronic passive balance due to the exports brought forward by the importers determines the depreciation of the national currency; a chronic active balance determines the growth of the exchange rate (national currency appreciation).

The commercial balance is the most important component of the *payment balance* that generates a statistical synthesis of the economical and financial relations of a country with foreign countries. The situation of the payment balance influences the exchange rate. A positive sold determines the growth of the exchange rate and a passive sold determines a lower rate. The passive sold of the payment balance can be liquidated through exports of goods, currency and by credits (loans) from abroad.

Usually, the short term loans generate sums of currencies that could be sold on the currency market, which stimulates the growth of the exchange rate. The long term loans determine a lower exchange rate.

2. Aspects regarding the evolution of the exchange rate in Romania

In the transition year of Romania, the factors that have depreciated the national currency had a more powerful influence than

the factors that appreciate it. Its depreciation meant the payment of a larger sum in lei for a foreign currency unit. For example, if in 1989 a dollar could have been bought with 14,9 lei, the exchange rate reached a course over 31000 lei (ROL) per dollar at the beginning of 2011.

For the level of the excise in 2011, euro was quoted at 4,2688 lei (RON).

A characteristic of the exchange rate depreciation of the leu was that it was done during the transition period in relation with all the currency and not only towards the dollar.

The exchange rate or foreign currency value depends on the demand and request existing on the market at a given point. In Romania, the demand and request for national currency can be observed at a macroeconomic level through the currency inflows and outflows at a national level and through the difference between this inflows and outflows.

The leu's exchange rate evolves under the influence of the supply and demand relationship towards the currency which is in turn influenced by various factors. The main factors that cause the increase of the lei supply and implicitly the growth of the exchange rate (national currency appreciation) are the following:

- buying economic assets, securities and real estate by foreign individuals and entities;
- borrowing outside the country by commercial banks and offering loans inside the country;
- formation of deposits in lei by foreign individuals and entities, in terms of a higher interest rate in Romania;
- using part of the currency gained by the exporters from Romania to make payments in lei. These payments are bigger when the economical activity is expanding;
- lei purchase by the National Bank from the market in order to prevent the fast depreciation of the leu;
- sending foreign currency in Romania by the Romanian workers abroad, to their families.

The main factors that influence the growth of the lei offer and implicitly the exchange rate depreciation are:

- the foreign investors capital return to their native countries;

- returning outside the country the loans made in foreign currency by the commercial banks of Romania;
- exchanging deposits in lei in deposits in foreign currency out of fear of interest rate lowering;
- buying foreign currency by the Romanian importers with part of the sums in lei;
- foreign currency purchase by the National Bank from the market in order to prevent the quick growth of the exchange rate;
- increase of the foreign currency demand in terms of declining confidence in domestic conditions;
- out of stock of a great number of foreign investors;
- sharp decline in the currency sent by Romanians abroad to their families in the country;
- reduction of domestic interest rates;
- higher growth of imports compared to exports.

A factor that has depreciated the leu is the inflation. During 2000 - 2010 the general index of consumer price in our country and some European countries is the following:

Table 1 - General index of consumer price in various countries in December 2010

Country	December 2010
0	1
UE – 27 countries	113,42
Bulgaria	139,30
Denmark	111,6
Germany	110,0
Estonia	129,94
Greece	120,37
Spain	115,09
France	109,75
Italy	112,2
Lithuania	130,51
Hungary	131,18
Poland	116,9
Romania	139,76
Sweden	112,27
Norway	113,30
Switzerland	104,0

Source:

http://epp.eurostat.ec.europa.eu/portal/page/portal/product_details/publication?p_product_code=KS-QA-11-002

It can be noticed that in Romania and Bulgaria, during December 2005 and December 2010, the consumer price had grown in average with about 39 percent, while in the EU (27 countries), the growth totaled only 13 percent.

A major role in the currency policy of a country has the Central Bank that manages the official national reserve funds. It intervenes in the forex market to stabilize the daily fluctuations of the exchange rate and to restrict speculation on the forex market.

In order to control and diminish inflation, the Central Bank makes internal loans difficult by increasing the interests of the required reserve so it can diminish the cash in circulation. During times of high inflation, the Central Bank absorbs part of the available lei offer by emitting securities with high interest and acts in order to increase the interest rate.

To the leu's depreciation have contributed the evolutions of imports and exports. The yearly advancing of the exports compared to the imports has lead to a lowering of the exchange rate and implicitly to the appreciation of exchange rate for various foreign currencies.

The leu's appreciation against the main foreign currency has both advantage and disadvantages. Among the advantages are:

- those who receive salaries in national currency and exchange them in foreign currency;
- people with debts in foreign currency because they pay less to repay the loan;
- the importers who can get foreign currency at a more advantageous exchange rate compared to the past;
- the buyers of energetic resources (gas, petroleum, etc.) with prices in foreign currency;
- the National Bank because a strong currency makes the lowering of inflation easier.

The ones at disadvantage are:

- the employees who receive their salaries in foreign currency because they exchange them for less lei;
- the exports because they face a diminishment of the external competitiveness and an invasion of foreign products on the internal market. They obtain less lei for the foreign currency gained through export.

Absolute Convergence: the Main Challenge in the Enlarged European Union

Bucur Iulia Andreea
Mircea Mirela Cristina
„Vasile Alecsandri” University of Bacău, Faculty of Economics
iuliaandreea_c@yahoo.co.uk
mcrst2001@yahoo.com

Abstract

Regional economic convergence issue has been and continues to be intensively treated and debated topic in the economic literature, not being able to accurately assess whether the process of regional economic growth is a convergent or divergent one. Multitude of studies and research in this area indicate the relevant subject matter and also the difficulties of analyzing the regional convergence and divergence processes and theoretical limits of the substantiation of European Union cohesion policy.

Key words: European economic integration, real convergence, divergence, regional disparities

J.E.L. classification: F15, O47, R11

1. Introduction

The literature that treats issues relating to regional economic convergence identifies two schools of thought dealing with this process. Adherents of the first one, the so-called “*convergence school*”, consider that deepening economic integration generates a progressive reduction of geographical disparities, while the advocates of “*divergence school*” think that the integration emphasizes the discrepancies between the countries participating at the final stage of economic integration.

Form a methodological point of view [1], the “*convergence school*” applies an econometric model based on theoretical principles of classical economics according to which the differences between the two regions in relation to wages or return on investment are offset, ultimately, by flows of goods and/or capital and labor mobility,

while the “*divergence school*” operates with a classical model modified by the introduction of new factors, such as so-called “*economies of scale*”. Based on the applied model, the “*divergence school*” advocates want to highlight the advantages of absorption likely to generate significant external economies. Thus, in case of a region, depending on the extent to which convergence or divergence factors predominate, the single market integration can have a positive, negative or neutral influence for that region. In other words, it is a “*subtle mix of factors problem*” [2] which can have a negative impact on a state in the monetary union, although the trade costs are significantly reduced per whole union, conclusion reached by Paul Krugman in his theoretical analysis.

In order to designate the European assembly economic convergence, there are two terms used: *nominal (conditional) convergence* and *real (absolute) convergence*. Harmonization on the *nominal economy axis* requires institutional and national monetary-financial policies changes for Member States (MS) imposed by Economic and Monetary Union (EMU) accession. *Real economy axis* aims to improve and gradually remove the disparities between MS and between regions through real convergence variables.

In relation to the process of real convergence, nominal convergence can be considered “*privileged*” [3]. This is *mainly* due to the attention given to the conditional convergence criteria stipulated in the Treaty of Maastricht, detrimental to the absolute convergence criteria that aim to ensure a high degree of structural similarity between the candidate countries. *Secondly*, also responsible for the nominal convergence privileged status, is the temporal dimension

implied by the achievement of the two processes. As is well known, joining EMU becomes possible only after the fulfilling of a series of minimum economic requirements in the form of nominal convergence criteria, but in a much shorter time horizon compared with the performance of real convergence.

2. Real convergence coordinates in the EU countries

Absolute convergence, seen as raising the standard of economic development level of a country or group of countries in regional integration, can be measured using instruments such as: *the level of economic development*, expressed by GDP per capita (calculated either based on the nominal exchange rate, or based on purchasing power parity (PPP) or the purchasing power standard (PPS)); *the degree of diversification of production*, expressed by the share of economic sectors to GDP; *the degree of openness of the economy*, expressed by weight of total imports and exports in GDP; *the share of bilateral trade with EU countries in total foreign trade*.

Based on the available statistic data and calculations and considering the indicators mentioned above as the most expressive in determining the degree of a convergence, we aim to evaluate it for EU member states.

The comparative analysis of GDP per capita level calculated on the basis of purchasing power parity (PPP), which can be traced in Table 1, we want to highlight *the degree of economic development* for MS.

Tabel 1. GDP per capita (in PPP) in 2004, 2007, 2009 (% of average EU-27)

	2004	2007	2009
Austria	127	123	122
Belgium	121	115	116
Bulgaria	34	38	:
Cyprus	90	93	98
Denmark	126	121	117
Estonia	57	70	63
Finland	116	118	111
France	110	108	107

Hungary	63	62	63
EU-27	100	100	100
EA-16	109	109	108

Note: :=data not available

Source: Eurostat, <http://epp.eurostat.ec.europa.eu/gm/table.do?tab=table&init=1&language=en&pcode=tsieb010&plugin=1>

The evolution of GDP per capita level in the EU and Euro Area has a general tendency of reducing during the enlargements so far.

The 2007 EU enlargement, when Romania and Bulgaria joined the EU, increased to 8,6% of the Union territory and to 6,3% of its population, but GDP per capita level measured in PPP has increased less in comparison with any other previous expansion. The lowest performance was recorded in Bulgaria, 38% and in Romania a value slightly higher, 42%. Both countries will have to recover in the coming years, significant gaps in terms of real convergence. In contrast is Luxemburg with an average of 275%, far from other MS. Overall, 14 MS have an average GDP per capita calculated on the basis of PPP below the EU-27 average, the other 13 states achieving higher values. If we consider the average value recorded in EA-16, we can appreciate that more than half of EU MS are situated below its level of development.

The situation is not essentially different in 2009 compared to 2007. In the EU, overall, there was a tendency to reduce the level of GDP per capita (in PPP).

Data presented in Table 2 regarding *the dynamic growth rate of GDP per capita* indicates its oscillatory trend for the period 2004-2009, with a decreasing trend since the last enlargement in 2007. Since the mid '90s, the EU has initially achieved a boom, the real GDP growth per capita has reached 3,9% in 2000 and, later, a slowdown with an increase

of only 1,3% in 2002 and also in 2003. In 2004 and 2005, there was a modest increase from 2% up to 2,5%. Between 2004 and 2009, GDP growth rate per capita has varied significantly among the 12 new MS (10 that joined the EU in 2004 and the two were joined in early 2007), some of them registering a very rapid GDP growth per capita and exceeding the EU-27 average.

In 2009 the situation could be translated by a general reduction in growth rate of GDP per capita, except Poland (1,7%), the largest decrease registering in Latvia (-18%). The 15 MS, including Romania, had in 2009 GDP growth rates below the EU-27, and 17 countries were below the EA-16.

Tabel 2. Evolution of GDP per capita growth rate in 2004, 2007, 2009 (% from the previous year)

	2004	2007	2009
Austria	2,5	3,7	-3,9
Belgium	3,2	2,9	-2,8
Bulgaria	6,6	6,2	-5
Cyprus	4,2	5,1	-1,7
Denmark	2,3	1,7	-4,9
Estonia	7,2	6,9	-13,9
Finland	4,1	5,3	-8
France	2,5	2,4	-2,6
Germany	1,2	2,7	-4,7
Greece	4,6	4,5	-2
Ireland	4,6	6	-7,1
Italy	1,5	1,5	-5
Latvia	8,7	10	-18
Lithuania	7,4	9,8	-14,8
Luxembourg	4,4	6,5	-4,1
Malta	0,9	3,7	-2,1
United Kingdom	3	2,7	-4,9
Netherlands	2,2	3,9	-3,9
Poland	5,3	6,8	1,7
Portugal	1,6	2,4	-2,6
Czech Republic	4,5	6,1	-4,1
Romania	8,5	6,3	-7,1
Slovakia	5	10,6	-4,7
Slovenia	4,3	6,9	-8,1
Spain	3,3	3,6	-3,7
Sweden	4,2	3,3	-5,1
Hungary	4,9	1	-6,3
EU-27	2,5	3	-4,2
EA-16	2,2	2,9	-4,1

Source: Eurostat, <http://epp.eurostat.ec.europa.eu/tgm/table.do?tab=table&init=1&language=en&pcode=tsieb020&plugin=1>

Regarding *the degree of diversification of production*, expressed by the share of economic sectors to GDP, we can appreciate, based on statistical data [4], the greater role of the primary sector in the latter two countries that become EU members, Romania (7% of GDP in 2009) and Bulgaria (6% of GDP in 2009), compared with the other MS, especially with EA-16. Also in these countries, services sector occupy a place below than other members. In the EU-27 and EA-16 the tertiary sector has a significant contribution in comparison to the primary and secondary sectors.

In analyzing real convergence the *degree of openness of the economy*, expressed by weight of total imports and exports in GDP has also a major significance. A low value indicates a low degree of openness of the economy of that country, while a high value signifies an economy with a high degree of openness. Therefore, for example, statistic data in 2009 [5] reveal that the Romanian economy (62,40% of GDP) is much less open economy than Poland economy (71% of GDP), the Czech Republic economy (130,20% of GDP), the Hungary economy (136,50% of GDP) and even Bulgaria economy (115,20% of GDP).

Regarding *the share of bilateral trade with EU countries in total foreign trade* there were not considerable discrepancies between Central and East European states that joined EU in 2004-2007.

3. Regional disparities in larger EU

EU enlargement to 27 MS forms a community and an internal market of 493 million citizens, which emphasizes economic and social disparities between the countries and their 271 regions.

Regarding to the regional disparities in terms of causality phenomenon the research has revealed a variety of economic determinants, which is reflected in at least *four basic categories* [6]:

(1) *Differences in competitiveness, more obvious after the integration of new countries or regions in the EU.* In order to improve them, there are a number of *conditions* [7] which determines the potential for economic growth and employment potential.

Sound macroeconomic policies combined with structural policies are essential in improving competitiveness, stimulating investment and capitalization, increasing both productivity and employment. It also increases the release rate and innovation, reduce the cost of capital and hence can record consumption and therefore consumption and wages can increase in relation to production real wages.

Efficiency and effectiveness of public administrations at national, regional and local level have a significant impact on economic development and job creation. For example, in the context of a poor administrative performance and changes in productivity level of public sector, the global competitiveness is directly affected.

Framework conditions and infrastructure facilities of various kinds – physical (in the form of transport and telecommunications networks), *human* (in the form of skills and know-how labor) and *social* (in the form of assistance services and other support services) – and the *capacity for innovation* have become increasingly important as competitive factors in recent years, closely related to *the acquisition of human resources for research and development* and *effectiveness* with which they are used.

Bridging the release mechanisms of convergence will inevitably be a long term process, which is why the least developed regions is the main priority of *cohesion policy*, although almost all regions are experiencing a continuing need for restructuring and modernization and promote innovation based on knowledge, in order to overcome the challenges of globalization.

The economic objectives [8] that aim, with the support of the cohesion policy, to achieve the real convergence of economic performance target, are stipulated in *the Treaty of Lisbon* and concern: *sustainable development of Europe based on balanced economic growth and price stability, on an intensely competitive social market economy, aiming a full employment and social progress, with a high level of environmental protection; promoting economic, social and territorial cohesion and solidarity among member states; maintaining the commitment to Economic and Monetary Union with the euro as its currency.*

Lack of a cohesion policy cannot provide certainty of achieving the so-called process of "catching-up" by the less developed states with growth rates of GDP per capita higher than those recorded in developed countries. Therefore, a well-founded strategy excludes the perpetuation of national and regional disparities and requires the maximum resource recovery policies available at EU level. Implementation of the EU cohesion principle is possible using two *instruments: the structural funds and the cohesion funds*, aiming to spread the new poles of attraction for business expansion into new areas of sustainable cohesion countries containers by tangible and intangible infrastructure development.

(2) *The existence of industrial clusters that perpetuates and accentuates the differences from other regions.* Economic reality has shown that economic prosperity in the EU is becoming less and less concentrated geographically, traditional economic "core" Europe (the area between London, Paris, Milan, Munich and Hamburg) recorded in 2004 a GDP rate substantially below the EU-27 one compared with 1995 while it share of the population remained stable. This trend is explained by the emergence of *new development centers* such as Dublin, Madrid, Helsinki and Stockholm, and Warsaw, Prague, Bratislava and Budapest.

Within the MS economic activities and population experience a high concentration throughout the EU capitals (except Berlin and Dublin). This is due, on the one hand, to the recent enlargements, and on the other hand, to the concentration of the growth process in the early stages of development in the most dynamic areas within the countries. In the long run, this could generate a restriction effect on economic growth. The pressures on the capital region (the so-called *negative externalities*), such as increasing housing costs, lack of space for commercial activities, congestion and pollution, negatively affects their image and competitiveness, a solution for this being the emergence of *secondary growth poles*.

(3) *The existence of important agricultural sectors and the lack of a sustained process of industrialization.*

(4) *The existence of geographically isolated areas and for which, among the others, the costs of transport are high (the*

periphery effects), such as: northern Finland and Sweden, the extreme south of Portugal, Spain and Italy and islands, including Malta and Cyprus. The higher costs of transport (partly caused by *rising energy prices*) may affect key sectors for many of these regions, such as *tourism*. Reducing accessibility constraints was possible by investment in airports and through increased efficiency derived from air transport companies with low cost, especially in *ultra-peripheral regions* (*Canary Islands, Azores, Madeira Island*), characterized by isolation from the main EU market, the domestic market failure, often fragmented across many islands, which limits economies of scale, the underdevelopment of the labor market that offers few skilled workers, and the fragility of ecosystems.

There are also *indirect factors* affecting the level of economic development in EU, such as *demographic changes, as the aging of the population, the slowdown in population growth and significant migration of population out of rural areas* that threatening future growth of employment. Moreover, there is a widening trend of regional polarization, meaning that big cities/capitals attract the younger population with higher education level. In parallel, the region faces a number of social challenges arising from the *distorted nature of the skills* (labor market segmentation between high skills/high wages and low skills/low wages, high immigration) in the frame of the economy value chain is moving to the knowledge-based activities and while institutions with a traditional security is eroding.

Years before the 2004 EU enlargement were appreciated by the European Commission with stable or increasing differences within the MS and with improving the overall development disparities across national borders, reality captured by the commonly used phrase "*global convergence, local divergence*". In 2004 the Commission summarized in the *Report on economic and social cohesion* at that time: *at national level*, cohesion countries continue to catch-up in development; *at regional level in EU*, is diminishing disparities; *at the regional level within the MS*, disparities continue to grow[9].

According to *the Fourth Report on Economic and Social Cohesion in May 2007*, the main beneficiaries of cohesion policy in the period 1994-2006, Greece, Spain, Ireland and Portugal have experienced impressive economic growth as a group. The lagging regions, particularly in NMS, which were the main recipients of support under cohesion policy during 2000-2006, showed a faster growth and faster reduction of disparities in terms of GDP per capita compared with the rest of the EU between 1995 and 2004. Strong economic growth in regions with a low GDP per capita over the last decade has meant that, overall, EU regions are converging trends.

According to the latest data, there are very significant differences between the EU regions, shown in Table 3 as a hierarchy of 15 most developed regions and the 15 least developed in terms of GDP per capita (in PPS) in 2006. Most are poor regions of Central and Eastern European countries that have joined during the last two waves of enlargement (2004 and 2007). Highest level was recorded in the region of Inner London (UK), 336% of the EU-27, while the lowest is found in North East (RO) of only 25% of the EU-27. However, many poorer regions have recovered significantly in the first half of this decade.

Table 3. Regions with the highest/lowest level of GDP/capita (in PPS), year 2006 (EU-27=100)

Regions with the highest level of GDP/capita (in PPS)	GDP per capita
Inner London (UK)	336
Luxembourg (LU)	267
Région de Bruxelles-Capitale (BE)	233
Hamburg (DE)	200
Groningen (NL)	174
Île de France (FR)	170
Oberbayern (DE)	168

Source: Krueger, A., *Statistics in focus. Narrowing spread in regional Gross Domestic Product*, Eurostat 75/2009

Despite progress in some MS/regions, absolute disparities remain, due to both the enlargement process and the territorial concentration of EU-27 GDP, lower in the traditional core of Europe but higher at the national level. Even some of the most developed regions begin to record growth rates very low or even negative.

4. Final remarks

Tension between nominal and real convergence processes is an issue especially fervent as the economic measures necessary to eliminate economic disparities sometimes disagree with those needed to achieve nominal convergence for obtaining the "admission ticket" to the euro area.

Sustainable convergence can be achieved only if we take into account the wider EU economy, context in which reducing disparities can take various forms. Lagging behind recovery process or improving and eliminating development disparities between MS and regions remains a subject with a particular significance for the economic, scientific and technological Union strategy.

In the long run, the real challenge for MS wanting to join the euro zone which must cope with is real convergence. It is natural that together with the EU 10+2 enlargements, removing trade and investment barriers and the free movement of labor to stimulate and enhance economic activity in these states.

However, there is no certainty of a quick takeover of the gaps, or in another word, less developed countries to have higher growth rates in the euro area overall, until the level of productivity and prices will not be substantially different.

Although most recent empirical research on economic convergence showed that there is and there cannot exist an alignment situation to real convergence for all countries or regions, the economic and social reality confirms the *process of dynamic group convergence*.

Quality Management Impact upon Human Resources Development

Bujor Anca Liliana
"Petre Andrei" University of Iasi
anca_bujor@yahoo.com

Abstract

The paper aims at dealing with the impact of the quality management on the development of the Human Resources- the only value-producing resource- as one of the fundamental requirements of the post-industrial society, as a process of getting to know the human beings, of their individual or group qualities, for their advanced development and for the good management of their creative potential.

The knowledge society promotes strong competition, grants a special place to the creation and the advanced enhancement of the human potential, both in terms of management and practice. From this perspective, HR quality management becomes an attractive item of high interest both for the employers and for the employees, especially for the accurate delineation of the success in relation to the failure, of the efficiency as related to the inefficiency of a human being's actions, for the management of the quality potential and of each employee's value.

Key words: Quality Management, development of Human Resources, Knowledge Society.

J.E.L. classification: M12

Knowledge of the assembly consisting of notions, ideas about world—objects or things, phenomena, processes, events—accumulated by society in time, determined, in certain moments, fundamental changes in society. Structured into procedures or theories specific to human activity types, diffused throughout world, knowledge accumulated have produced—in certain historical moments, changes in the structure of society types, as well as in the life of human individuals. The fact that industrial revolution (occurring in the beginning of 17th

century) is the phenomenon which comprised the entire mankind, moment overcome through the appearance of idea, knowledge regarding post-industrial society [10] as a new cultural type, with a dense civilization, borderless, with a record-time communication, comprising space and time for inter-communication is significant. Information revolution is fundamental for such society, which starts with accumulating a volume of unprecedented knowledge. The fact that information revolution is at the same time revolution of knowledge, developing the new society type—knowledge society within which, Daniel Bell [2] shows the main resource which generates the new type of social revolution became knowledge. Knowledge gained in this process make specialist place—the "one who knows", became essential within a knowledge based society.

Knowledge is a complex bio-psycho-social process, is a relation between the knower and the object in relation (subjected to knowledge) with direct effects in getting knowledge allowing objective world information assimilating and reconstructing by the subject [7]. As a multi-dimensional process it is incorporated into organization technologies, rules and procedures, culturally imprinted under the form of rational perceptions, values histories and convictions, materialized into abilities, expertise and aptitudes or conceptual and attitudinal cognitive comprehension specific to human groups or collectivities.

In such a context, human resources management makes its content fit, mainly pursuing efficient administration of the most precious and active resource belonging to whatever organization—people—who, individually or in group participate in attaining their own or organization own objectives. This makes possible that in practice organization management should be oriented towards company inside, to the

competitive advantage source, respectively in people's capacity, and their knowledge. Future will confirm opinion according to which to gather, organize and utilize knowledge in a performing way will become sources of competition advantage since success is based on knowledge and creates new knowledge.

In knowledge based society, variable *knowledge of organization employees* will become dominant in relation with material actives, with financial resources, actually representing competitiveness secret. Thus, knowledge management in a company supposes catching, applying and generalizing value gained from creativity, expertise and performing expert experience of employees.

Present civilization, Alvin Toffler [10] holds constructs another step, another fundamental existence on other grounds and with other structures, tightly centralized and standardized, that bring about on life plan intellectual activities as well, the ones based on knowledge, obtained through specific informative way. In order to be operational, each organization needs instruments, capacities, energies, funds, material values, however they become viable only if they are known and evaluated by man, resource without which organization does not accomplish its mission. In their socio-professional structures in an organization are, therefore active factors that which individually and collectively contribute to accomplishing its objectives.

At least from this perspective, human resources management, as a dimension of organization management, is grounded on human factor quality principle—the one which assures company success. Human resources management directs its steps towards man, towards developing some efficient practices of improving training as well as for employee promoting, it settles down its policies in the field of qualitative development of human resources and the way employees perceive organization preoccupations for its own development. The dominance of this activity consists of employee forming and training in performing qualitative achievement of organization activity and its inner structures, of the forms and modalities by which personnel is motivated to participate in accomplishing its purpose in the total given parameters.

Human resource management is only one dimension of total quality management and comprises processes for directing and controlling organization as regards human resources in organization quality for identifying and administering those activity types necessary for achieving organization quality objective and policy in this field, organization purposes and responsibilities which, implemented through proper modalities give new values to human resource quality and implicitly to organization itself. I think that to determine quality performing activity of employees, the only who substantiate to human resource in an organization remains fundamental: what employees do for their own overcoming, process through which performing accomplishment of organization objectives are assured, therefore what they also do for organization: the way they prepare themselves, achieve performance, respectively the quality of their own becoming, their own activity. I notice that the way to a new human resource quality supposes competitiveness, intra-organization competition and not only, that is individual should be in a permanent competition with his own self and with team or organization partners. Human resource quality supposes the consciousness of one's own participation to self development, to highly efficient and performing activities such as the elaboration of action strategy from individual able to place him to superior value levels in the act of working. Human resource quality is therefore given by (remarkable) professional, relational and acting capacity of employees, determined knowledge and practices gained in an acting process, activities with different degrees of difficulty and that offer a higher profit and which, finally allow solving more or less difficult problems, according to pre-established standards.

End of 20th century realities and beginning of third millennium bring about a new conception about society and its organization structures, conception grounded on the problems of post-industrial society [10] whose content is given by "excessive organization, by an "intelligent organization", "knowledge based organization" [4], organization structures whose existential structure is becoming knowledge, intellectual dominant which

gives contents to entire existence, human society and activity.. For the period we are passing, abilities, engagement spirit, creativeness, and increased efficiency/performance - become essential elements of human individual's activity at intra- and inter-organizational level able to differentiate each structure contribution under conditions of knowledge-based economy [6]. Human resources, this time, make difference between company success or failure, therefore of human individual integrated in activities settled down by organization

So, under conditions of knowledge-based society and economy, organization management and within it career management should incorporate in their contents both organization and employee interests and preoccupations as the only value creating source. This process brings to attention general aspects of organization functioning, a phenomenon which is accomplished with identifying what is common in human individual activity within dynamic and flexible career. Post-industrial world becoming, accentuated by IT&C, by ample knowledge processes whose finals are given by knowledge made possible the production of unprecedented changes of the forms of human actions, in labor structuring, especially in its globalization and also in appearance of digital work with effects in modifying people's working and living styles. Tele-activities, tele-working, tele-socialization etc. develop as forms of modern labor of digital economy based on knowledge and intelligence Thus, all these impose a new approach of human resource, of man organization integrated, an approach in which man's and his activities qualities should come first. Irrespective the form it is achieved, occasional, at home, quasi-mobile, with random timetable or totally mobile—supposes large scale of work mobility, it is a complex process which supposes establishing and promoting of a special *status-role* between employer and employee since tele-labor is negotiated under its all scientific, technologic, social, financial etc. tele-labor does not lower employee's statute, on the contrary, it enforces and develops it, manifesting into a qualitative functional flexibility, because it is his voluntary choice to act in certain exigency and quality

parameters [8]. The work new content is given by thinking and creation, knowledge and intelligence, objectified in knowledge, information and abilities, a phenomenon which fundamentally changes employer-employee relationship whose dominant is cooperation, and also labor market within which employing policy will be intellectual expertise on project.

Post-industrial realities of informative knowledge-based society changes problems of quality of human resource management need, of performing, value career. Career choice and orientation become much more complicated processes and career course guiding and developing should pursue more carefully assurance ever optimal concordance between general and specific training peculiarities included into position.

Research we carried out was oriented to investigating training and developing process of personnel in some organizations in the county of Iasi, Romania, by deciphering employee training and developing peculiarities, starting from hypothesis that if a company subjects represent value creating source, this will assure qualitative development of its personnel through judiciously organizing training, preparation and development of its own employees. Target population come from 95 companies with large activity-research- development sphere and high-tech, industry, agriculture, pisciculture, construction, services, trade, tourism and consists of 406 subjects of whom 125 managers of various levels, formed in technique, law and economics and 291 persons with large occupational beach from about all activity fields and a preparation proper to positions.

For achieving new quality in personnel performing preparing and development, information collected in research work reflects directions of human resource assurance, respectively, activity and task concentration on positions (aspect underlined by most subjects within sample), qualitative work organization able to performingly engage personnel in its total personality structures, to highly evaluate subjects capacities, knowledge and abilities (92% of subjects) of learning and improving their own preparation (84%), creating decent working conditions—physical action environment, motivation, creative psycho-social climate,

transparent personnel policies corresponding to individual and organization objectives (98%).

Concordant with these aspects is information obtained as regards main activities for career organization administration, as dominants for determining and accomplishing organization human resource quality, activities from which profession and given profession categories careful and profound knowledge are detached as human individual testing and employing measure aiming at uncovering human individual knowledge, ability, behaviour ability in relation with position standards (88%), promoting differentiated management according to employees development degree, to their age, knowledge and experience aiming at determining socio-professional identity with the entire charge of knowledge and behaviour, for more adequate but qualitative engagement in the acquired role-status (92%), considering that profession life is dynamic, innovative, situation when employee regards organization which must pursue his becoming in a stability-transition relationship, and according to working place change frequency, offering him support for his own formation and improvement through gaining new information, knowledge, abilities according to the new work content given by knowledge society realities (80%)

Realities detached from research also bring about other aspects of organization management for obtaining new values in human resource qualitative development, above all for evaluating employees contribution to their own formation and development in career self-administering, a process characterized, mainly, by existing availabilities in employees in this respect: over 98% of persons forming general research sample (406 subjects) are preoccupied by existing possibilities in organization for their own socio-professional development under performing conditions, preoccupied with developing their capacities, expertise, their future roles as well as opportunities of performing affirmation, image of self construction through relating to others, complex self-knowing . Self-estimation process becomes both a challenge and a real introspecting modality, self-analysis and comparing his own activity outcome, of organization self-development of

human individual, a phenomenon promoted by 82% of research subjects; Forming his own abilities in consensus with quality and performance standards established is both a human resource quality management to be found in 85% of the persons investigated and which has as a support self-knowing, respectively, what they can do with their own career development. Organization preoccupation for determining needs and opportunities of career individual development, respectively, planning need of each employee, an aspect which remains a desire for 78% of sample components, but must start with self-knowing and self-estimation process and completed with exploring opportunities created within organization as well as outside it as a result of as rich and correct informing about profession world and imposed quality criteria.

Therefore, employee formation remains fundamental condition for achieving an organization performing quality and it implies career management value whose content is given by both organization and individual management. The process pursues company objectives, tasks, and needs inter-conditioning, harmonization with employee's ones as an active, creative economic agent within inter-dependence of internal-external factors intra and inter-organization, processes amplified by knowledge-based economy in a competitive dynamics of professions that increase the needs of performing quality of human individual, of rapid organization integration.

My research bring to attention, beyond expressed desires, the preoccupations of investigated business milieu in the field of human resource quality, mainly through activities accomplished regarding personnel formation, improvement and development. Thus, out of 85 companies that form the research sample only 24 (28.2%) have elaborated strategies, policies and programs of personnel training and qualitative development, in conditions in which only 48% of companies declare themselves satisfied with their employees' value.

It is worth remarking that out of the 24 organizations that have elaborated training programs, in which 96 subjects took part (57.5%), of whom 52(63.4% are managers. And 44 (52.4%) production workers, 5

companies (20.8%) pursued strategies after career stages, comprising 10 (12.2%) managers and 21 (25%) production workers.

Inter-conditioning strategy type use with company type which have elaborated training programs, 37.5% of them utilized strategies after response of organizers which 96 (57.8%) subjects of whom 52 (63.4% are managers and 44 (52.4%) production workers, 5 companies (20.8%) pursued strategies after career stages, comprising 10 (12.2%) managers and 21 (25%) production workers, aspects synthesized in graphic.

Detaching from research these aspects regarding employees' participation in programs of knowledge and ability development through training reflects both companies and employees preoccupations in this direction which, corroborated with desires expressed give in fact the state of facts in the milieu investigated. Company as well as participant structures in strategy structures confirm the care given to performing training of human resource. 37.5% companies utilize strategies according to organizers' responds, 41.7% strategies according to financing possibilities and 20.8% according to career stages. Correlating these dimensions with employees' participation for training, improving and their qualitative development attest the consciousness becoming degree like also employees' participation, be they managers or production workers (total 406 subjects of the sample) in programs of development in profession: only 40.9% participated through strategies enumerated in programs of qualitative development, of whom 65.6% are managers and 29.9% workers, 36.7% used self-preparing modalities and 62.3% participate in organization settled programs. The situation is totally uncorresponding if we relate these realities to the whole sample (406 subjects) 25.9% of total sample of training programs in career organized by company, 15.0% self/managed their self training and 50.0% did not participate to any professional training form, this in conditions of knowledge based society.

Information obtained in research of problems of managerial preoccupations with human resource qualitative development in some organizations from Iasi, Romania business milieu reflect existing state of facts in a field which measures human resource

quality, therefore organization value, reality characterized by very small number of companies that practice training and qualitative development programs of labour force (29.2%) small groups of participants in training programs (40.9% of which one third self-managed their training (36.7%, only 18.7% of participants in training programs utilized strategies according to career stages. Reality confirms the fact that organization management involvement in human resource qualitative development is episodic and only to overcome critical situations making knowing employees' qualities, personality features, knowledge, abilities in view of applying proper treatment in order to obtain from them qualitative accomplishment of organization and individual objectives, modelling in this way both company and its personnel opportunities in conditions of flexibility in the long run, reaching qualitative parameters in a successful career.

Mentality and Paradigmatic Shifts Needed for Building a Global Quality Culture in Formal Education

Bundă Nicoleta Ramona

„Ovidius” University of Constanta, Faculty of Economic Sciences

bundaramona@gmail.com

Abstract

Quality culture encompasses a more implicit consensus on what quality is and how it should be maintained and promoted. Nonetheless, this paper is based on the conviction that quality culture can be consciously promoted. The procedure of promotion described here after is based on the agreement of common goals from which indicators of success and quality measures are derived. By a conscious promotion of a common quality culture in international cooperation, potential failure of the partnership can be diminished because contradictions with existing quality cultures at partner institutions are avoided and the partnership is firmly based on common goals as the focus of cooperation.

Therefore a common quality culture or, more broadly, a global quality culture may emerge if the mentality of confrontation is abandoned. The single suitable rule is the cooperation. Applying this rule each step towards a global quality culture should be taken cautiously. There is need of an entire process based on intercultural dialogue. The agents of each culture should interact until the harmonization of their values, beliefs, standards etc. As a result, a new culture will take form which is not a mere sum of the former ones.

Key words: quality culture, global intelligence, formal education

J.E.L. classification: B15, B52, I25.

1. Introduction

At national and regional levels the education is important for its promises for future economic growth and development. Even the neo-institutional theories depart from the human intrinsic cognitive systems

and follow all the way to the same end point: economic performance.

This is not the only way, but it is one of the most sophisticated economic demonstrations for the role played by education in the contemporary world.

2. The call for mentality and paradigmatic shifts

Yet there is a growing awareness that we all are lost if continue to follow the economic way. Some global approaches to world education change the direction toward a global intelligence. That is: “the ability to understand, respond to, and work toward what is in the best interest of and will benefit all human beings and all other life on our planet. This kind of responsive understanding and action can only emerge from continuing intercultural research, dialogue, negotiation, and mutual cooperation; in other words, it is interactive, and no single national or supranational instance or authority can predetermine its outcome. Thus, global intelligence, or intercultural responsive understanding and action, is what contemporary nonlinear science calls an emergent phenomenon, involving lifelong learning processes”. (Spariosu, 2005, p.3)

How can global intelligence be acquired?

It involves remapping traditional knowledge, accumulated and transmitted by various educational disciplines, and finally dropping out the disciplinary mentality. The global intelligence presupposes a holistic mode of thinking, a trans-disciplinary or integrative one, and also new kinds of knowledge from an intercultural perspective.

Yet, a global mode of thinking will emerge from “local” knowledge with its own historicity. Knowledge is always bound to a specific time and place, to a specific culture or system of values and beliefs or, indeed, to

a specific lifestyle. A global approach attempts to identify the cultural specificities of knowledge, explore commonalities and differences among them, and negotiate, if need be, among such specificities. It also presupposes that, in the process of exploration of cultural commonalities and differences in the way in which we acquire and utilize knowledge, new kinds of cross-cultural knowledge emerge through intercultural research, dialogue, and cooperation, and new kinds of integrative cognitive and learning processes become possible. (Spariosu, 2005, p.8)

Then there is a need for designing educational models to foster the kind of local-global learning environments and intercultural, intellectual climate that are needed for sustainable human development in the next few decades.

The current educational system privileges imitation students, not creative, critical, and analytic professionals with a broad and disciplinary free understanding of society at large. The core challenge for educational institutions is to turn away from conventional lecturing to learning situations based on the search for solutions to real-life, open-ended problems. (Denzin et al., 2003, p.134)

Innovative education practices for sustainable human development covering all three types of education (formal, informal, and non-formal) must be encouraged. These practices will be configured to provide a good spread of activities focussing on all three pillars of sustainable development: environmental, economic and social. Their innovative character should come from mission and objectives assumed, the delivery method of educational services and the institutional frameworks.

There is a large scope for systematic and trans-national educational reform to change the current situation of powerful constellation of forces through cooperative and innovative practices.

Paradoxically, the ongoing economic determinism of development process can be counterproductive. All the demonstrations of the economic development theories formalized or not, are very interesting intellectual exercises that unfortunately bring just little long termed benefices for human beings. Even more these benefices are not shared equally and equitable to all the people

of the world. It is high time for return to natural and simple things. People always had the inclinations to struggle for survive or to cooperate for surviving. The economic institution – market is probably the most populated field of battle throughout history. Are we prepared to imagine a world in which competition is totally replaced by cooperation? And yet we wonder the project of global economy undertake only the disappearance of many types of frontiers? In market terms this means that finally we'll have a larger battle field.

This is the call for mentality and paradigmatic shifts. It should be abandoned the mentality of confrontation and look for other ways of organizing human relations, as well as our cognitive and learning processes. The shift will take place gradually, much impeded by the tendency of path dependence. This shift enhances a learning process that changes the national cultural filter and prepares the emergence of a global culture. Once such conditions installed, it will enable proliferate of global intelligence. From the paradigmatic perspective, in our opinion the neo-institutional approaches still find a place in this landscape of scientific inquire based on mutually, intercultural cooperation. A new set of economic, social and politic institutions should be crafted to guide all of our future interactions on this planet. This new rules of game borne from cooperative actions, but not confrontational selection process will naturally lead ourselves to the achievement of the final goal – that of the sustainability of human development.

3. Toward a quality culture in formal education

Within the economic, social and ecological axes of human sustainable development, quality has a significant importance and represents a challenge since quality assurance in formal education has more and more come to the fore in recent years.

Quality is a multi-faceted concept, difficult to render operational in educational terms. In general, there are a number of quality concepts as regards formal education programmes. All of these are seen as relevant and competing. In fact, there is a strong belief that a 'one-fits-all' concept of quality is not desirable. Instead, differentiation is

much welcome in view of differences of needs and in order to match a broad spectrum of individual and economic demands.

Among the quality concepts of formal education are – just to mention only the most common ones here –, according to broadly accepted typology: quality as (a) perfection or consistency, which is linked to notion of reliability and to conformity through compliance with set standards; (b) the exceptional or excellence, which bears an element of elitism; (c) fitness for purpose, often linked to the need to address to a required reference point; (d) value for money, which is sometimes linked to the notion of value for time invested, both of which relate more closely than other definitions of quality to the quality concept of – partly rational and partly emotional – customer satisfaction; (e) transformation, considering the individual gain accrued in the course of a learning experience.

Positive definition of quality approaches are necessarily paralleled by negating or abandoning others. Here the slogans ‘from input factors to learning outcomes defined in terms of competences’ and, which is partly related when seen from the viewpoint of process and approach, ‘from teaching to learning’ and ‘student-centred learning’ come to mind. Despite profound and serious difficulties in defining the content of learning outcomes and relevant competences, in validating them, in making them operational, in installing fit-for-purpose learning devices and environments, and in measuring their accomplishment, the shift to learning outcomes and to student-centred learning rather than focussing on input and teacher perspectives has been one of the key mantras in the quality debate. However, there is still no denying of the relevance of input factors, such as qualification and numbers of staff, of equipment, or of student intake. So in practice, from case to case, there seems to be considerable ambivalence between rhetoric and traditional reality in defining and measuring quality features.

The likely key to consolidating all these approaches is that all factors need to be linked in a methodically correct manner. This is done by not taking input factors as isolated starting points for developing and judging quality. Instead, input factors should rather be seen as elements to be considered

incidentally when addressing the question as to whether or not the envisaged educational purposes could, in terms of underpinning both at the level of concept and of its subsequent implementation, feasibly be accomplished.

It clearly results that quality cannot be solely evaluated by calculating quantitative indicators, such as: the number of students per member in the teaching staff, educational spaces etc. Other specific indicators are even more important: the professional and methodological competence of the teaching staff, the cultural, ethical and social accountability of education, student satisfaction. Consequently, a quality education depends, to a large extent, by the synergic harmonization of three elements: institutional capacity, educational efficiency and quality management.

To this end, a functional emerging educational system should capitalize on the following aspects:

- educational goals, curricula, teacher competence and the efficiency of educational practices;
- educational spaces, equipment, libraries and reading rooms;
- performance criteria, standards and indicators, internal and external evaluation pertaining to such standards and causes of dysfunction;
- the amount of financial resources.

The success in setting up a “quality culture” is influenced by objective and subjective factors, by national and global trends. Some countries have set the trend and the others need to follow in their footsteps. This is about the assertion that the majority of countries have understood the expectations of the minority of leading countries in the world economic hierarchy. Each of them is just a piece in a puzzle called the Global Economy, which needs to adjust to fit in. Very much like a diligent student who learnt his/her lesson well, the governments set priority action plans which will directly impact upon the future development of the national education system.

How can such plans be accomplished? How can we achieve a global quality culture? The necessary steps are easy to set, hard to achieve and impossible to quantify, as tangible results become visible in many years. Firstly, one should improve the quality

assurance system at pre-school, primary, secondary and tertiary levels, by assisting schools to improve their management and supply relevant jobs for the labour market. Secondly, improving teaching competences and the competences of the people involved in the educational system by supporting them in their life-long learning process. Thirdly, one needs to extend the life-long learning framework by assisting the agents/suppliers of life learning education to reach the standards of quality management assurance. Fourthly, young researchers should be encouraged to develop their competence by increasing their doctoral and post-doctoral educational opportunities. This enumeration can continue indefinitely. It will be interesting to note, however, whether such desires, expectations and actions pertaining to a "quality culture" will ever take effect in a national culture. In retrospect, forthcoming generations will easily solve this problem.

For the time being, the majority of countries are currently importing patterns and solutions created by developed countries. Although quality assurance activities have not had a long tradition worldwide, some countries or groups of countries have obtained worthwhile results. Therefore, the mission lies in promoting "compatible quality assurance systems" meant to render national education internationally recognized. In more concrete terms, we need to set in motion a mechanism meant to ensure that educational establishments observe national and international quality assurance standards. To this end, quality assurance strategies mirror the ability of an educational supplier to be accountable to internal clients (pupils, students, teaching staff) and external agents (employers, society) and ensure that standards are met. This quality assurance becomes an important factor in the invisible competition between nations in terms of culture and education.

Consequently, judging by the promise of progress it delivers, we consider that the implementation of a quality assurance system is necessary, yet far from being accessible, due to certain specificities: the school is not a factory, students are not goods/commodities, there are multiple clients (students, parents, employers, the society) and so one cannot identify precisely all the elements of a manufacturing process. Despite such

specificities, quality management can be functional in education as well. The educational process can be improved, teaching efficiency can enhance and teacher/student satisfaction can increase. Quality management stands for a different way to organize and harmonize efforts so as to ensure that people fulfill their tasks enthusiastically and actively contribute to improving their techniques. It might look rather impossible, yet practice provides us with plenty success stories for this type of management. To increase the chances of success, one needs to observe a simple principle - the process should prevail over the product. Such management will capitalize on the learning process as such, rather than on the results evinced by tests and examinations. From this perspective, the human factor is in the foreground again, and we consider that the weak spot which management should address is individual attitude towards the educational process. We need to consider that both the student and the teacher act and interact under complex incentive structures. We need to identify those mechanisms to induce perceptions and values meant to ensure the quality of the teaching activity. Quality culture derives from this; it stands for cooperation and responsibility.

4. Conclusions

Educational discourse is replete with references to the process of building a quality culture inside the educational system. In particular, the issue of educational quality has become an area of great interest and concern due to the conviction that education plays a pivotal role in global economy sustainable development. In choosing to investigate continuity and change surrounding learning process, the questions rely on the contextual and evolving character of the process. The ideas elaborated in this chapter point to the fact that education is a "path dependence" phenomenon. Knowledge acquisition is underlain by perceptions derived from the process of collective learning across generations. The act of learning is a cumulative process subject to social and cultural filtration. The overall social approach to the benefits of expanding knowledge (in various stages of historical development) is the major source of long

term change. Likewise, educational improvements are dependent on the features of social institutions and the institutions are variables strictly influenced by the level of education. Hence social institutions are likely to become inertial to change. How can one overcome this obstacle? Economics can provide at least one solution: joining the efforts of researchers coming from different economic areas can lead to worthwhile progress with respect to unveiling the causes and mechanisms of change. Thus, progressing onto a continual ladder of discovery and learning, horizons will broaden, and the prevailing patterns of thinking and perception will become more flexible.

The distinctiveness between formal, non-formal and informal education determines a shift in focus. Learning is a culturally – filtered and cumulative process. Most reforms should be targeted at informal education. The pre-school, primary, secondary and tertiary levels of education form a complex edifice which needs to be built in gradual stages.

Meeting international quality assurance standards is not against this principle; on the contrary, it is quite compatible. It will make us aware that we are in competition with other participants/players worldwide and only quality players win. According to the guidelines developed by this paper, the authentic and enduring progress in the quality formal education is only triggered by reforms targeted at informal aspects pertaining to the national institutional paradigm. This is the unique way to create a real global quality culture: the continuity of national specific reforms and the gradual change towards “universal” values imposed by the winners of global competition.

The global quality culture is fully compatible with the global intelligence. One emerges as a result of the other. This is the supreme stage, but we haven’t reached that point yet. For the moment we could speak mainly about different national quality cultures and common quality cultures of joint educational programmes. Some steps are made toward the global quality culture, but in the light of neo-institutionalism, they are illusory because even the international standardization of education is just a formal initiative. Merging standards and processes

doubled by the promotion of intercultural enquiry especially through non-formal/informal education will conduct us to a global culture, in general, and a global educational culture, in particular.

The Corporate Social Responsibility Theory in the Context of Globalization

Butnaru Gina Ionela

gina.butnaru@uaic.ro
balan_ana84@yahoo.com

Abstract

Corporate social responsibility (CSR) is a contemporaneous research topic due to the impact on the companies concerning the aspect of the favourable image of the customers and of the local communities, and also concerning the increase of the economic and financial results, and the employees and the people from the area of influence of the company through the contribution to the realization of social, cultural and economic objectives.

The aim of this article is to analyze the following aspects: the notion of corporate social responsibility and its components, the present-day stage of knowledge, the general concept of finality of the company, the relationship between the corporate social responsibility and the equity theory and how much the social responsibility of the companies is considered by the system of management of the company.

Key words: corporate social responsibility, globalisation, managerial ethics, equity

J.E.L. classification: M14

1. Introduction

The phenomenon of globalisation, emphasised in the internationalisation of production and of commerce, leads to important changes in the corporate understanding and realisation of business strategies. First of all, we can notice the intensification of the international competition, each participant on the market trying to improve the quality of products and services offered in order to sell them in higher quantity, and with advantageous prices.

However, globalisation shows that the companies are not evaluated anymore nowadays exclusively on the basis of the quality of products and services offered, but also according to the contribution to the social life of the community to which they belong. As a result, it appeared the concept of corporate social responsibility (CSR), being in a continuous clarification and improvement process in what concerns the theoretical and practical content.

Developing its activity in a very diverse and exigent social environment (unionist, political, cultural, familial, religious, of associations, regional, etc.), in order to be responsible from a social point of view, a company needs to communicate and to have an honest and open dialogue with all its internal or external partners: stakeholders, employers, customers, providers, the community in which the company develops its activity, formed by the citizens of the areas of interest, the civil society, the local administration, the government, etc.

2. The state of knowledge concerning the corporate social responsibility

The speciality literature is not very rich in CSR analysis. The issue is approached in indirect contexts, as in the case of corporate economy school books, especially in French speciality literature. Thus, Jean-Pierre Lorriaux shows that in the past (in general, the first half of the 20th century), the company emphasised its economic function [3]. Its rule of action was the following: „to follow efficiently and loyally the economic finality and the social finality will be reached by overgrowth”.

Thus, the economic finalities were on the first level (especially assets operators' satisfaction), and the social finalities can be

realized only if there is an increase of the economic indicators of results, beyond the intended values. A new phenomenon has appeared in the last decades, the fact that the company cannot be in harmony with its environment if it does not intend to reach a social-human finality, following explicitly objectives of social progress, which are the result of the intervention of the public powers, employees, unions, consumer associations, mass-media, citizens, nongovernmental organisations, etc.

As the speciality literature mentions, the conceptual bases of the corporate social responsibilities were founded by Andrew Carnegie, at a great extent by his 1899 essay entitled "The Gospel of Wealth". Carnegie emphasised two principles: the charity principle, and responsible administration principle (stewardship principle). According to the first principle, people who became rich through their businesses have the obligation to support the less fortunate members of society. The second principle states the fact that the rich companies and individuals should use their money as trustful administrators for the rest of the community, multiplying the social wealth by cautious investments.

Another approach of social responsibility is realised by prof. dr. eng. Liviu Marian regarding the relationship between this concept and managerial ethics [4]. Social responsibility is defined in correlation with notions of ethics, deontology, morale, needs, then he emphasises the historical issues in the evolution of social responsibility and managerial ethics, the categories of social responsibility, the costs and benefits of social responsibility, the evaluation of social responsibility, the methods of improvement of social responsibility and managerial ethics. The social responsibility as seen through the perspective of managerial ethics "states the managers' obligation to choose and to apply the actions which contribute to the individual well being, in consensus with the interest of the society and of the organisation they are leading".

In Romania we can notice a relatively detailed approach of the corporate social responsibility in a work appeared in the year 2005 [5]. Some of the aspects analysed are the following: the presentation of different opinions concerning CSR, the association of

CSR to a source of profit, the history of the term, the description of the main components and characteristics, CSR and the culture of the organisation, elements and instruments of CSR evaluation, case studies concerning CSR in Romania, etc. Here is the CSR definition given by the European Union: „a concept by which a company voluntarily integrates the preoccupations towards social and environmental issues in business operations and in its interaction with interested partners". The following CSR integrated elements were identified: mission, vision and values, business ethics, management and responsibility, economic development of communities, involvement of communities, environment, human rights, market practices, and policies at the work places.

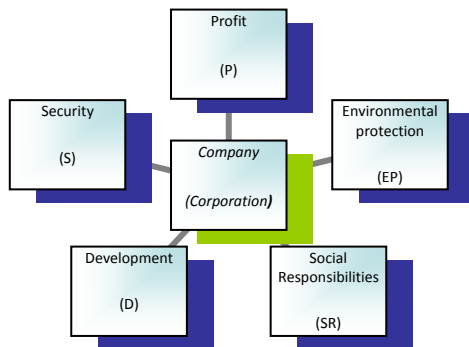

We must stress the fact that corporate social responsibility is a much larger concept in relationship with corporate philanthropic activities, or with the donations and help offered at different communitarian activities. A study realised by the consultancy company Braun & Partners Romania in the area of Bulgaria, Poland, Romania and Hungary shows that Romania is on the last place in what concerns the corporate social responsibility in human resources with a percentage of 6%, the hierarchy being as follows: Hungary (17%), Poland (15%), Bulgaria (7%), Romania (6%) [7]. 25 companies with the highest income were chosen from each country. In what concerns the companies, it was proven that they did not have specialists in social responsibility. The same, the study emphasised the weak performances in social responsibility, showing that the companies that integrated CSR fundamental rules and principles in their system of values and business strategy had greater chances to survive the present-day crisis.

3. The fundamental finalities of the enterprise (organisation, company or corporation)

In the science of economy and the enterprise administration, as well as in the science of management, the company or enterprise is considered to have four fundamental finalities: profit, security, development and social responsibilities [1,3].

Taking into account the present economic and social demands, we add yet another important finality of a company or corporation, namely: the environmental protection, so that we can say that the firm or corporation has five fundamental finalities, as it is presented in figure nr. 1.

Figure 1 The fundamental finalities of the company

The concept of finality of a company means the reason of its existence, the objectives or goals for which it functions [2]. Another definition shows that the finality of an organization means the system of values which the finality itself establishes, and from this point of view, any organization seeks to complete its finality or finalities.

A much wider formulation is the following: the essential, first class finality of any company is the accumulation of wealth together with its desires and with those of the society in which it develops its activity. This interpretation combines in a way two of the five essential finalities, namely the profit and the social responsibilities. Consequently, the company's finality has a philosophical-political character, and it is an element of permanence of the system of values.

In what concerns the company, there are two possible meanings of the finality. On one hand, it seeks to realise only its own finalities, or, on the other hand, the finalities which are insured by the economic system. These two meanings are applied to different companies in the market economy (private business or public companies).

Generally, the finality is qualitative, but at a certain point a company can aim towards the realisation of each of the five finalities in the order of priority established by the management system.

The profit (P). This represents one of the companies' essential finalities in the market economy, because through it they intend to realize certain benefits, or a profit, i.e. to be profitable. In the company's finality the profit itself must be considered a necessity, a must.

Security or survival (S). The firm or company is an economic "cell" developing its activity among other competitive "cells", fighting to live and to survive. The companies' security, as a characteristic of the finality, means therefore survival in a strong competitive environment, stability, security of profit and avoiding the bankruptcy.

Development or growth (D). This finality consists mainly in the creation of new products, the modernization of the existing ones, the elaboration of new ways of production, and the modernization of the existing ones. Development is not limited only to production; it also includes the possibilities of use from which the consumer can benefit, even modifying the product, the distribution circuits, the selling methods etc., all this requiring sales promotion. The same, the development of a company can also be done through a systematic policy of concentration and diversity. The most important element for the growth of a company is developing its capacity of production and selling, which is possible only with expenses for investments.

Environmental protection (EP). The environment is formed of two categories: the natural environment and the surrounding environment. The natural environment includes a group of elements which can be analysed, described, measured and studied using the instruments of physics, chemistry and biology. This group is heterogeneous, including plants, animals, soil, subsoil, climate, landscape etc., forming a complex system inside which the life of human beings unwinds, along with all its characteristics. The surrounding environment has a wider area of influence, including both the natural environment and the environment transformed by people, artificial or anthropomorphic, clothing, food, means of transportation etc., and also residues, wastes and remains from the substances resulted from production and consumption processes.

The concept of ecological management has been developed during the past decades, also called green management, referring to the environment administration, which should be a preoccupation of both economic agents, and public administration, of some national or international institutions, and also of some pressure groups.

Social responsibilities of the company or corporation (SR). These responsibilities must be analysed from two different angles, namely: according to the personnel of the company or of the corporation, and also according to the society as a whole. The personnel of the company, actively participating in reaching the established objectives, is expecting it to satisfy some of their social needs, like: accumulating an adequate and safe income, sponsoring certain social actions, improving life and work conditions, offering some aids etc.

Also, the company has certain social responsibilities towards the local communities where it is located, like: participating in building some local social objectives, services development, sponsoring some actions and activities etc. Realizing these responsibilities has an important role in forming a favourable image among the company's clients.

If we consider the five finalities, the company has the possibility to choose one or several directions of action from the 120 possible strategic combinations, given by the permutation of the five finalities, i.e.: the number of strategies = $N! = 1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 = 120$. In these 120 strategic combinations, each of the five finalities appears by a number of times determined in the first place, the second, the third, the fourth, and the fifth, as it follows: 1. P, S, D, EP, SR; 2. S, P, D, EP, SR; and so on.

4. Corporate social responsibilities and the theory of equity

Nowadays, a pretty well established theory has been developed concerning the concept of equity and the practical ways of materialisation in companies and in society as a whole through their management system. Thus, Jean-Marie Peretti's book entitled "Les clés de l'équité dans l'entreprise" is to be noted, book which appeared in Édition d'Organisations, in 2004. We present some

ideas from this work in order to show the connection between the theory and the application of equity and CSR.

The term equity appears very often in political and managerial speeches. The investigations show that the solicitation of equity is very strong at present times, and the managerial speech often makes reference to it. The dimensions of equity are largely approached and the demand of equity is necessary from a political, social and economic point of view. In an economic context where the inequity risks are numerous, developing some equity managerial and economic measures is absolutely necessary in order to build, keep and reinstall trust [6].

Today, the problem of equity is omnipresent in society. The citizens expect the state to introduce and favour equity everywhere: equity between the employees of private companies and the civil servants, equity between the different ages, equity between the managing personnel and the rest of the employees, equity in the contribution which forms the national income, equity in Europe etc. Consequently, it is necessary to have a higher demand concerning equity in management and building a more equitable society and company. Making precise rules in the equity management and applying them is more and more imposing. The employees openly express a great equity attention in what concerns the incomes, the formation, the promotion, the evaluation and mobility, identifying equity as a justice based on the contribution of each one to the labour and income.

The theory of equity is used in order to explain the individual and collective behaviours at work and in society, thus contributing to the explanation and clarification under a social and economic aspect of the numerous problems in the field of human resources and management at micro-economic and macro-economic level.

The equity can be internal and external. The internal equity consists in the fact that the employees compare themselves to other employees of the company, which will result in equity or inequity. The external equity appears when the employees compare themselves to persons outside the company who do the same work, thus leading also to a state of equity or inequity.

5. The management system of the company and corporate social responsibilities

The corporate social responsibility (SR) welcomes the theory and practice of equity because it implies that the companies' responsibilities towards the society are much more important compared to the responsibility of maximizing its economic value which goes back to the owners or stakeholders.

We must emphasise the reality that the managers of the companies are not receptive enough to the demands of social responsibility. They are preoccupied, as mentioned above, with the maximisation of the dividends of the company's stakeholders. They explain this attitude by stating that the social responsibility is costly for the company and they are not willing to use part of the company's profit in order to act according to the requirements of social responsibility.

The theory of equity presented in the previous paragraph does not mean equalitarianism. It only involves equitable differences in the payment by guaranteeing each employee a worthy evaluation of their contribution. Also, it involves policies and actions which meet the expectancies of equity and of corporate social responsibilities requirements.

6. Conclusions

From a theoretical point of view, we can say that there are at present enough elements in order to get a larger image of CSR. However, CSR should not be separated from the other four fundamental finalities of the company: profit, security or safety, development and environmental protection. These are the very reasons from which CSR was presented in this work as a distinct component of the fundamental finalities of the organisation.

On the other hand, CSR should be considered through its correlations with managerial ethics and equity of responsibilities and advantages of any nature.

The same, a point of view almost unanimous is that CSR should be included in the business strategy of the companies, as it results from the 120 sets of possible strategies. Consequently, it should be provided in plans and programs, and thus it should be evaluated and measured accordingly.

In a continuously changing world, in which economic crises and of other nature periodically appear, people wish a greater involvement of the companies in solving social issues in order to overtake their different needs and difficulties determined by troubles from the social-economic environment.

Performance, Efficiency and Efficacy – Approach for an Economy Based on Knowledge

Butnaru Gina Ionela
„Alexandru Ioan Cuza” University of Iasi
gina.butnaru@uaic.ro

Abstract

Performance is a very contemporary concept, which in the specialists' opinion has two components: efficacy and efficiency. Consequently, the knowledge society approach of performance generates the result of the knowledge revolution. The value that could be generated by knowledge depends on this performance. The present work has the intention to present several specific aspects concerning the concepts of performance and managerial performance, and their classification in a society of knowledge and information, called knowledge based economy, or knowledge society.

Key words: knowledge society, performance, and managerial performance:

J.E.L. classification: M19

1. Introduction

At present time, **the knowledge society** is a concept which took shape in the best known universities, research and consulting centres from the developed countries, where a series of economy and management specialists are involved, with the conviction that people are rapidly moving toward a new type of economy. With no second thoughts, specialists consider that this new type of economy can be called “economy based on knowledge”. Its main characteristic consists in “taking on the science and technology top realisations, and by utilisation, their transformation in a competitive advantage”.

In this context, the **economy based on knowledge** is the result of the knowledge revolution. The revolution should produce first in the mind of the receivers of knowledge, **performance** on which the value that can be generated by that knowledge

depends. In a company based on creativity, possessing by the employees of a big volume of **knowledge** is essential for obtaining the **performance**.

In order to accumulate this knowledge along their entire activity, employees who wish to be **performant** and creative should appeal to three sources of **knowledge: their own, attracted, and bought**. Most of the Romanian specialists mistake the knowledge of the company with the one of the person who accumulated it, not taking into account the knowledge accumulated by the company during the years of activity.

The knowledge specific to each employee is at the origin of the competitive advantage of the company based on creativity;

The attracted knowledge (the attracted sources) which enriches and multiplies the employees' knowledge are the Internet, web-sites, electronic libraries, scientific reunions, fairs, exhibitions, etc., sources that cost little and are easy to access. In the Western countries, there are special structures in the companies dealing with attracting knowledge.

The bought knowledge is that for which certain persons are willing to pay in order to access. This is especially sought by people with a high level of training, and it refers to:

- speciality studies, certain computer programs, projects, etc.;
- sending the employees once or twice a year to training courses with the costs supported by the company;
- training courses for the workers, work exchanges with similar companies, with the purpose to increase the workers' volume of technological knowledge, with effect in the increase of work productivity;
- for the specialists from the intellectual elite of the company: studies for master's degree, doctor's degree, post-doctor's

degrees, research topics with international participation, scientific communications, national and international congresses, etc.

Performance has two components: **efficacy**, representing "*the ability to establish proper objectives and their realisation*" and **efficiency**, term used since the ancient times, because it represents "*the ability to use at the best the resources available for the realisation of the objectives.*" [1].

The economic efficiency was defined along the time more and more specifically for the application field. Efficiency is approached as a maximisation of the outcomes of an economic activity (Adam Smith, 1732/1790). Economic efficiency is a characteristic of productive or unproductive activity, of consumed/utilised resources and products, of assuring useful effects in a certain quantity, structure and quality by the reasonable use of the existent resources.

The reasonable use of the resources can be assured in two ways: *the allocation of material, human and capital resources* in an optimal structure or by the *management and technology used* (Petre Jica, 1989).

Gheorghiu (2004) presents several types of efficiency, depending on its reference to a certain field: technical, economic, social, cultural, administrative efficiency, etc. The use of the standard economic value to measure both the efforts and the effects is a distinctive element for the economic efficiency as compared to other fields of activity, aiming thus the minimisation of the resources which correspond to the unit of useful effect.

The economic efficiency is a measure of realisation of an intended objective. Being regarded under double aspect, quantitatively and qualitatively, the economic efficiency is the ratio between the features of the economic phenomenon under analysis, expressed by one of the two forms: *the direct form* – as the ratio between *effects*, i.e. income, and *effort*, expressed by circulation expenses, and *the indirect form* – the ratio between the effort and the effect [2].

In his work, the writer Nicolae Lisandru emphasises that there are two fundamental functions of the efficiency: *the optimal efficiency function* of each unit and *the social function of providing* the population

accordingly with the necessary products and services. Consequently, the efficiency of the activity of an organisation can be followed and evaluated from two points of view: "*from the consumers' point of view, which is the social efficiency, and from the organisation point of view, which is the economic efficiency itself, calculated as a ratio between the expenses of live and material work and the outcomes obtained as a result of the sales.*" [3]

After consulting the literature, we can say that social efficiency "is aiming, as *central objective, the maximisation of the social satisfaction, i.e. the satisfaction of social needs by comparing the system of indicators of the quality of life with the system of indicators of social effort.*" [2]

In what concerns the economic efficiency, we can say that it comes as a component closely related to the social efficiency, due to the fact that it is hard to imagine an impeccable service for the consumers without a high level of economic efficiency of the organisation, determined by the functionality and management corresponding to the activity developed by the organisation. As a result, the economic efficiency of the activities of the organisations implies obtaining a maximum profit in the context of the minimisation of costs and expenses. Therefore, the economic efficiency appears as a ratio between the expenses which should be made for a good development of the activity of the organisation, and the income obtained from selling the products and services offered by the organisation.

The manager's performance is related to the level of the abilities and the psychological and physiological group motivation at a certain moment in the human being. *Information, thinking and innovation* are three attributes in the differentiation process of a company. The economist Myrdal Gunnar said in Rome Club: "*The use of the mathematical equations and of a huge calculator where to register the alternatives of some policies abstractly conceived by "a model of global simulation can impress, but it has no scientific validity"*". In this situation, the key word is *to learn together* (the manager and the group he is leading).

In the literature, we understand by **the efficiency of the economic activity** "*the ratio between the economic effect realised*

and the outcomes obtained by an economic agent, or the ratio between the outcomes and the effort." [4]

The effort is measured by the consumption of economic resources necessary for the development of the activity in an organisation, and the outcomes by the volume of the profit obtained from sales, and we can also consider in addition other qualitative effects of the economic activity (the increase of work productivity, the decrease of the relative level of the circulation expenses, promotion of technical progress).

The economic efficiency also means *"obtaining useful economic and social effects with reasonable expenses, savings in what concerns the technical, material, working and financial resources. Its determination is based on a systematic approach, due to the interdependence between the economic processes, between companies and collaborating branches."* [6]

2. Managers' performances and astral colours from their aura

Before being appointed, managers are evaluated by the specialists in all the aspects, according to more or less real criteria. Nobody uses in the managers' selection the criterion of the colours in their aura, aspect emphasising the best the cognitive, intelligence, psychic, mental and health aspects. The term "astral" is less used. Beyond the physical plane, also called the third dimension, there is another plane, more subtle, over the physical plane, known as *astral plane*. Most of the people have a latent perception of the astral plane, but there are exceptions from this rule, and they are the clairvoyant. The colours from the human aura, produced by emotional and mental states, belong to the astral plane and are called *"astral colours"* and they are perceived by the senses belonging to the astral plane, being invisible from the physical one.

If colours can be seen in the managers' astral aura, their significance is as follows:

- *red* is the phase corresponding to the mental activity, manifesting in body vitality, health, creativity, optimism. It is also manifested in different shades;

- *blue* is the spiritual, psychic side with dominant inclination towards high ideals, altruism, veneration, devotion for a cause;
- *yellow* is the mental, intellectual phase of the managers' activity, necessary in taking strategic decisions which influence the future of the company, reason, logic, thinking processes, synthesis;
- *white* is the pure spirit, the managers' positive pole, which should be found in all their activities. It is made of all the spectrum colours, being considered a neutral colour;
- *black* is the negative pole of the being, the negation of the spirit itself. The presence of this colour in the managers' aura makes them not corresponding for this position, their activity having a destructive character.

The personal aura strongly influences other persons with whom the managers have a relationship, and they can therefore influence indirectly their business partners. From this reason, in their way towards perfection, the managers should develop their personal aura in order to obtain the necessary qualities to realise the objectives of the company, and even to neutralise the negative ones that are blocking their progress.

The managers can realise this phenomenon in two ways:

- to develop in their aura the most powerful vibrations and colours stimulating progress and creation by keeping the mental images in their minds, by repeating their wishes and the objectives;
- the additional effect of the mental images of the colour of the aura corresponding to the ideas and feelings they wish to develop.

In other words, as the physical capacity develops through movement and use, the mind develops also by its use. The thoughts maintained by the manager (or by a person) affect the people around, attracting them in the harmony of their thoughts, enriching their auras with elements from their own auras. This explains some statements like "I have been influenced by X." This ability can be favourable to the managers in business negotiation processes, developing themselves a strong personality, becoming positive and attractive persons.

Each person is a reality of the manifested thoughts. Managers should be willing to manifest and to develop the desired objectives, and to restrain the negative mental characteristics. A thought generates another thought which we use in order to create other more powerful thoughts, essential method in the decisional process of the managers based on the relationship between the colours of their auras and the mental evolutionary corresponding states.

The managers' method of improvement using the astral colours in their auras consists in the formation of a mental image of the colours they desire, after which they project their vibration in the aura through a personal effort of will, removing the uncertainty and fear. The idea and the presence of the desired colour should be retained mentally as long as possible, and the habit to represent the image and the vibration of the colour will create itself. This is the way that managers could create an aura leading them to success.

Once the managers constructed an aura to assure them success in life and in business, this aura should be protected from the outer negative influences, i.e. to become immune to the psychic, mental, physical, spiritual, negative influences, and the ones coming from the external environment. This protection is realised by enriching the **performant** aura with colour and vital magnetism, capable to reject the external malignant influences as the use of drugs, alcohol, tobacco, coffee, or the gambling.

Powerful managers should have in their aura vibrations of mental protection, represented by the astral colours orange, yellow, and other similar colours. These colours offer mental illumination to the managers, making them receptive and with great power of judgement, essential quality in choosing to make a decision from several possible alternatives. The interaction with other auras will stop at the protecting aura, gliding along, and there will be no influence. Around the **performant managers'** body a golden aura or a halo will dominate, which will be as a protecting helmet against the business partners' assail. The emotional side has a protective aura, too, which is of great importance, if we take into consideration the fact that many of the actions of our lives are under the impulse of our emotions, and less through reason. The protective emotional

colour is blue. The blue coloured aura would be like a protecting shield for the managers.

3. The psycho-professional profile of the performant managers

The managers' leading position should be doubled by the effort to reshape themselves, to structure their personality, attitude and behaviour according to a certain psycho-professional profile. In order to have a brilliant professional career, satisfaction and social recognition, managers should fulfil the following conditions:

- to permanently learn, to study in order to maintain the access to the technical and scientific progress, to be convinced that the chance for success awaits the bright minds;
- to know one or two languages of international circulation, to be able to work on the computer, to have a drivers' licence, to know how to use modern telecommunication systems;
- to keep the professional activity on the first place, to arrive on time, to be tidy, to have the ability of an intense rhythm of work;
- to be good negotiators, to be calm, to master the situations, to be sociable and open to human relationships;
- to appreciate the value of time, to be impeccably dressed, always adapted to the moment;
- to have the strength and the moral force to overtake the failures.

There are also other demands for a manager to be successful, but beyond the professional competence which is so necessary, the socio-human quality has a special value. Without these qualities, the managers' success and also the success of their decisions are not possible. *Let us remember: there is no substitute for character, brains could be bought, but not the characters. Managers, respect people's dignity!* People, no matter the sex, age, professions and training feel the strong need to be respected and valued, and treated as personalities in themselves. The deepest principle of the human nature is the wish to be respected. Any of the managers' evaluations and decisions concerning an employee creates a reaction of satisfaction or disappointment. The reproachful speech can bend the employees, but not the victory, in

what concerns their convictions. The manager, before making a decision, should seriously meditate regarding frightened, stressed, humiliated people, with low self-esteem. But attention: managers, do not torture your employees, do not miscall them, do not use nicknames! Communication should be in a civilised, serious and positive language.

4. Conclusions

Performance and managerial performance are two different concepts, but in a close relationship, which could influence one another in a society based on knowledge. We must take into account the fact that managers have great powers in their organisations, and by their decisions they influence human destinies and success on the market, and as a result – the performance. Only a performant management, with professional managers, is capable to managerial performances, i.e. to generate economic, financial and social performances. *And not to forget, as a famous saying states: „success is a trip, and not a destination.”*

The Evolution of the Purchasing Power in Corelation with the Prices

Cazan Doinița
Cucoș Alina-Florentina
„Dunărea de Jos” University of Galați
zafiud@yahoo.com
saracu_alinaflorentina@yahoo.com

Abstract

The most important criterion used in Romania to assess the buying power is the average wage, also an accurate indicator of the general evolution of the state's economy. The economic crisis and the overall decrease of earned salaries, for both private and public sectors, deeply affects the way the consumption costs for Romanian families evolve. After two decades of economic reform, Romania is still among the last countries in the European Union, regarding the quality of life and the access of people to goods and services necessary for normal standards of living in modern societies.

Key words: purchasing power, inflation, salary, consumer price.

J.E.L. classification: E21

1. Introduction

The purchasing power reflects on the number of products or services that can be bought with a monetary unit. When the level of the income of the population stays constant and the prices raises, the purchasing power decreases.

The purchasing power stays constant if the income multiplies with the index of inflation. The purchasing power can be showed through the report between the index of the income of the average monthly net salary and the index of the consumer price.

In january 2007, consumers from Romania had the lowest purchasing power from EU, although in Romania it was not registered the lowest minimum salary in the economy from EU. While in Bulgaria the minimum salary in the economy was 92 € in Romania this was 114 € a month. The causes of this phenomenon comes from the fact that in

Romania, GDP (Gross Domestic Product – PIB) for the year 1990 was equal with the year 2004, while the level of the income in 1990 was the same only in the year 2006.

After the year 1999, the difference between the real income of the salary and the real average medium pension increased. In january 2005, the report salaries / prices was 86,7%, and in november 2006 was 97%. Only in december 2006, after 16 years of transition in Romania the purchasing power came back at the level of october 1990 (when the liberalization of prices and hyperinflation started).

After the change of the political regime, people didn't stand anymore in crowded quenes in order to buy the basic food. A year or two later, the national economy was affected by recession, after the fact that in 1990 the purchasing power increased with 10 % than in 1989. Even for satisfying the minimum decent expenditure (consum), the money of the most of the population was not too sufficient.

2. Analysis correlation between Romania and other countries in the European Union

A period of a relative recovery of the purchasing power was registered only in 2007, when this increased with 16 % in comparis on with 1989. In april 2008, the increase of the purchasing power had reached 31,5%. In these conditions Romania had the lowest rate regarding the purchasing power from EU – 204 points, followed by Bulgaria with 216 points, Latvia - 310 points, Lithuania – 324 points, Slovakia – 351 points, Estonia – 362 points. The highest purchasing power from EU is and it was in countries like Luxembourg, UK, the Netherlands, Belgium, France or Ireland.

Table 1 The lowest purchasing power from European Union

Source – Eurostat, 2008

Table 2 The highest purchasing power from European Union

Source – Eurostat, 2008

The years when the purchasing power of the income of the medium net salary in the economy had values more below the year 1990 were: 1993 – 1994, over 42 % , but also 1997 – 2002, over 40 %. If in 2004 (when the inflation was calm) the medium net salary in the economy was of 1974,5 times higher than the one in January 1990, the prices increased 237,8 times. In 2004 the medium gross salary was about 800 lei, than 2950 in 1989, and the purchasing power was 83 % in 1990.

In EU, the purchasing power is also defined in correlation with the minimum salary in the economy. In EU there are major differences regarding the minimum salary in the economy. The value of the employees that had the minimum salary is: 16,8 % in France, 16% in Bulgaria, 12% in Latvia, 0,3% in Lithuania and 9,7 % in Romania.

In Romania, the purchasing power of the minimum salary had the tendency to decrease between 1990 – 2008, reaching the minimum level between 1999 – 2000, when the real minimum salary represented a quarter of the real minimum salary for the year 1990. From 1994

until 2002, with the exception of the years 1999 and 2000, the purchasing power of the minimum salary was about one third from the year 1990.

The inflation in Romania registered two top moments - in 1993 (the inflation rate – 256,1 %) and 1997 (the inflation rate – 154,8 %). Between 1990 – 1995 the inflation rate had three figures, but after that until 2005 it had many figures. After 1990, the inflation caused a show decrease of the purchasing power of the estate allocation for children.

The periods of time when the allocation for children had the lowest level was between 1992 – 1996 and 1999 – 2008, the lowest rate of the purchasing power was registered in 2000 (2,6 % for the allocation of the first born child and 37,1 % for the allocation of the second child).

The purchasing power of the pension of the farmer was in the communist period, in the transition period and even in the present, much lower than the average pension of social insurance. Only in 2004, the situation of the farmers in agriculture started to improve.

In 2007, the purchasing power of a pension in agriculture was higher than the level of the year 1990 with 39,5 %, and in 2008 with 56,4 %.

All of these explain why in 2007, according to a study of the World Bank , only 30% of the romanians people believed that their economic situation improved after 1989, while 40% of them believed that the communist period was much better for the economy, the living standard, the political situation and the level of the income.

Thus, for the population with medium and minimum income, which come from the social service, from agriculture or from the recession salaries given by social services, the necessity to satisfy the needs of goods and basic products generated big existential tensions, especially between 1992 – 1995 and 1997 – 2007.

The Households Wealth and Debit Monitor of Romania made by CEE relates that the net financial resources of each Romanian raised to the sum of 407 € , which means at a national level almost 8 billion € or 7 % from GDP. These resources are active in cash, bank deposits, life insurances, investments in mutual and pensions funds and stock. In comparison with the financial

resources of each bulgarian, for example (909 € 34% from the bulgarian GDP per capita) or of each hungarian (3227 € 38% from the hungarian GDP per capita) and each polish (3156 € 45% from the Polish GDP per capita), the romanian person is, by far, the poorest european.

In 2007, the bank deposits of the population were about 900 € per inhabitant in Romania, 1300 € per inhabitant in Bulgaria, 2000 € per inhabitant in Poland and 2500 € per inhabitant in Hungary.

Thus, a bulgarian saved 40 % more than a Romanian, in the conditions when Bulgaria had a GDP per capita with 25 % lower than in Romania.

Tabel 3 Bank deposits in 2007 in about four countries in the European Union

Source – Eurostat, 2008

3. Conclusions

After 1990 a lot of Romanians took huge risks and had difficulties, they went to work abroad to earn more money.

According to the World Bank, the money sent by romanians from abroad took Romania on the eight place in the top of the countries which had money from the population that works abroad (about 9 billions dollars in 2008, almost one third more than in 2007).

This money represented 3 - 5% from the GDP of Romania in the last 3 – 4 years having a big contribution to the economic increase and the wealth of the population.

But this money caused the explosion of the local expenditure, having a huge pressure on prices from all the economic areas and, especially, in the real estate area (the increased demand – the increase of the prices) and in the exchange of foreign currency.

„Value” in Economic Theory and Practice

Călean Ioana

„1 Decembrie 1918” University of Alba Iulia

ioana_c20@yahoo.com

Abstract

The recording gauge used in the provision of economic information to conduct various analyses and comparisons is “value”. This concept has been used in the economic and social theory and practice and has existed in human reason since the beginning of mankind. The studies regarding the shaping of value in different economic contexts have been the subject of many articles and publications; each research having its particularities in terms of approach and enunciated conclusions. The material finality of studying value is the addition of value – the fundamental goal of national, multi-national and international companies that not only economists are trying to exploit to the fullest. It is only the result of the complex management of all aspects belonging to an entity, which must combine the use of the set of resources in an economic, efficient and effective manner in order to achieve the desired performances and results.

Key words: value, value paradigms, value analysis.

J.E.L. classification: M 40.

1. Introduction

The addition of value begins since the selection, choosing and evaluation stage of the strategies adopted by the management of the entities based on value. Therefore, increasing value isn't just about the obtained results and performances, but is also about relying on the study of the close and harmonious connection between the parts and elements that have contributed to their achievement, monitoring carefully the effects, as well as the generating causes of the effects. The benefits of the value-based management may be dissected as follows: the continuous maximization of creating value,

improving the company's transparency, facilitating communication with investors and analysts, harmonizing the interests of the managers with the interests of the shareholders, preventing the underestimation of the actions, establishing clear priorities for management, improving the decision-making process through the judicious planning of the allotted resources, encouraging investments that create value, offering support in complex problems that have high risks, setting targets for reward. In contrast, the main “disadvantages” of value-based organization, management and administration are: in most cases, it requires a change in organizational structure, the difficulty of using value-measuring instruments because of their high cost and excessive detailing of the issue, which may lead to overlooking the essence of the problem; the risk of including the wrong elements in formulas may lead to the presentation of a loss of value and, last but not least, it requires string support from the administration boards [1].

2. Research methodology and motivation

Generally speaking, the research methodology is a set of procedures, methods and techniques used in scientific research.

Researching means answering a question or seeking an answer. It isn't just studying. The study is a preliminary stage and is indispensable to research, but not more than that. This is the essential part of research – the problem or question that the study shows, enriches and tries to solve or answer – that it is the centre of what has to be done and if the reason exists, eventually a whole will exist too [2].

The importance of studying this subject is based on the fact that adding value and scientific research have become one of the main and essential tools used by most countries of the world to ensure sovereignty,

independence and economic, social and cultural progress. A tributary of these ideas, Edward A. Murphy stated: "To steal ideas from a person is plagiarism; to steal from many is research"[3].

By looking at the concept of "value" in different economic situations, the objective of the paper is to analyse the notion in various terminological constructions, such as: the paradigms of value, the market value, fair value, recoverable value, customs value, etc. The working procedure consisted of identifying the area of study, choosing the research subject, collecting data and information from literature, from the economic activity of the entities and from available data bases - search.ebscohost.com, www.emeraldinsight.com.

3. The conceptual spectre of value

According to the Romanian Explanatory Dictionary, value is the attribute of things, facts, ideas and phenomena to meet the social needs and ideals generated by them; the sum of qualities that give price to an object, a human being, a phenomenon, etc.; importance, meaning, price, merit, precious, expensive, of value; valuable, deserving, with authority.

In economic theory and practice, value represents the monetary expression of a product or service [4].

The first economists, such as Adam Smith and David Ricardo, considered that the value of a good or product depends of the amount of labour needed to produce it, while more contemporary economists believe that the product's utility for the consumer determines its value. Economists today accept that both factors, demand and supply, are important in determining the value of a product, by establishing the market value of that product.

4. Paradigms of value

The value theory holds a central spot in economics due to the controversies around the value-generating factor.

Because of the polemics regarding the determination of value and of its social and political implications, the stance on value has generated genuine economic schools and currents of thought. In this sense, D. Ricardo believed the issues of value were the key of

deciphering the whole economic mechanism, stating: "If I could overcome the obstacles in the way of giving a clear insight into the origin and law of relative or exchangeable value I should have gained half of battle" [5].

The intuition of exchange value has emerged since ancient times during the period of Xenofon and Aristotel who noticed the two attributes of a good (value and use value). The mercantilism theory, which saw the source of value and wealth growth only in the area of commerce, were soon eliminated from economic science by physiocrats, who believed value is an expression of utility and rarity and saw nature as a creator of wealth and additional value. Referring to value, Condillac, a physiocrat, stated: "Value is not an attribute of matter, but represents our sense of its usefulness and this utility is relative to our need. It grows or diminishes according as our need expands or contracts".

The objective theory of value considers work as a homogeneous area, common to all goods, which allows measuring and comparing this value, on which the exchange is conducted. A. Smith said "the real price of everything, what every thing really costs to the man who wants to acquire it, is the toil and trouble of acquiring it". Therefore, work is the real measure of the exchange value of all things. This theory is known as the labour theory of value, being founded by A. Smith and D. Ricardo, and subsequently taken over by K. Marx. Actual labour is what creates the use value of goods, and abstract labour seen as a mere consumption of physical and intellectual energy determines the actual value, the measure of value being, in the opinion of Karl Marx, the socially necessary labour time. The other production factors (capital, past labour and nature) get involved indirectly in the process of obtaining value through work (alive), the single factor that creates value.

The limits of the objective theory of value are reflected in the generalization of the role of labour in obtaining value and consumer exclusion. This aspect was noticed by the founders of the subjective theory of value, through the contribution of the three neoclassical schools of thought: Vienna, Laussane, Cambrigde. The priority of the new theory is to explain the balance price by turning to the concept of marginal utility. Value has a purely individual and subjective

determination, being created by the appreciation of each consumer of the last consumed quantity of a good, which implicitly involves the goods' degree of scarcity.

The specificity of the objective theory of value is to acknowledge the three main production process factors – labour, nature and capital – and especially introducing the consumer next to the producer into the mechanism of determining value and giving him equal rights.

Trying to reconcile the two theories was attempted by the leaders of the schools in Lausanne and Cambridge, particularly by A. Marshall, who promoted the symmetric theory of value. Based on this theory, the price of goods, as an expression of their value, is determined by the simultaneous influence of demand and supply. Marginal utility and the price paid to acquire a good are important for the consumer, while the factors' consumption and the obtained incomes, therefore the efficiency of his activity, are important for the producer.

The contribution of Romanian economists is obvious during the process of elucidating the value, especially the contribution of professor Paul Bran, who brings to attention the concept of entropic value in the paper "The Economics of Value", the process of obtaining value being, in the opinion of the author, a process of entropy, changing the natural, social and economic potential and finding the necessary inputs only partially in the new product. Values are a result specific to entropic transformations in which the production processes, the consumption process, the processes specific for the environment and for social life are participating.

Regardless of the meaning of paradigms of value, its social acknowledgement is found in the price of the good. Comparing it with the effort made to obtain the product represents the essence of economic efficiency; this is why the attention that managers must pay to the process of obtaining value is essential, knowing that "a good value isn't random", as L.W. Crumm, the author of "Value Engineering", noted.

5. The inflexional forms of "value"

"Value" is found in the construction of a wide range of concepts used frequently in economic theory and practice. Among these, we will focus on the following terminologies:

- Book value: represents the value at which an assets is recognized in the balance sheet after deducting the accumulated depreciation to date, as well as the losses accumulated through depreciation (IAS 16 "Tangible assets"). Romanian regulations define net book value as the value at which an asset is recorded in the balance sheet after deducting total depreciation. It may be noted that national regulations use a concept to refer to the assets presented in the balance sheet, and International Accounting Standards use a different concept. Therefore, we use the concepts of gross book value (the recording value of the frozen assets, either at the time of entry or the re-evaluated value) and net book value (the recording value minus the calculated depreciation and constituted provisions).

- Fair value – recent global events have determined the need to increase the importance of the information written in financial statements. Therefore, there is more emphasis on the benefits of using fair value, which is "independent, credible, consistent and well founded" [6].

Fair value is a generic term, a desideratum, just like providing an accurate picture is the general accounting objective. It isn't an assessment criterion included in the accounting conceptual framework, nor a certain type of value, it is a pure accounting concept that reflects the economic reality of an entity in terms of its assets.

Fair value is defined as being the amount at which an asset may be exchanged or a debt settled between informed parties, of their own free will, during a transaction in which the price is determined objectively [7].

The most important merit of current economic rules is that, in the future, the role of accounting in supplying information in daily transactions will be considerably bigger.

For example, S.C. Alfa S.R.L. decides at the end of the year 2008 to conduct a revaluation on the basis of an evaluation made by an authorized evaluator for a land that was calculated at a fair value of

100.800,00 lei, resulting a revaluation value of 79.533,56 lei. At the end of 2009, due to prices lower by 20% for real estate caused by the economic crisis and due to compliance with regulations that stipulate that "revaluation should be conducted with sufficient regularity, so that the book value is not substantially different from the value determined by using the fair value at the date of the balance sheet" (OMPF 1752/2005), the entity should conduct another revaluation and the statement at 31.12.2009 would be summarized as follows:

Table 1. calculus statement for land

Record value	Net book value	Fair value	Revaluation difference
21.266,44	21.266,44	100.800,0 (31.12.2008)	79.533,56 increase
Results an increase of the asset's value, which will be highlighted in the account 105 „Revaluation reserves”			
100.800,00	100.800,00	80.640,00 (31.12.2009)	-20.160,0 reduction
Results a reduction in the asset's value, which will be highlighted in the account 105 „Revaluation reserves”			

(Source: the pre-working of the real-information given by the financial situations of the company.)

Revaluation, due to lower market prices in 2009, has lead to a negative influence on the balance sheet's frozen assets and equity, which ensured an accurate picture.

- The production value, called also production cost, represents the entry value - book value of the fixed assets produced by the entity, which consists of the acquisition cost of the raw and consumed materials, other direct expenses and the share of indirect expenses rationally related to the production of assets. Romanian entities that apply the International Accounting Standards must exclude the selling expenses from the production cost and acknowledge them as expenses of the period.

For example, to achieve a new manufacturing recipe, S.C. Alfa S.R.L. made the following expenses: materials 800 lei, labour 400 lei, electricity 50 lei, water 10 lei. After completing the research, we find the company complied with the conditions for the recipe to be considered an invention:

☞ receipt of the manufacturing recipe (work statement or delivery bill):

„Development = „Revenue from 1260 lei
costs” the production
of intangible assets”

☞ moving the manufacturing recipe in the category of patents (transfer note):

„Concessions, = „Development 1260 lei
patents, licences,” costs”
brands and other similar
rights and values”

- *Market value:* represents the current price (rate) of financial securities, which are transacted on the stock market, or the value at which an economic good may be sold on the free market at a market price.

6. Conclusions and research perspectives

The concepts that are built around the notion of value are far more numerous, but this paper addressed only a few of them in order to show a number of economic contexts in which this concept is extremely important. This paper may the prospect of studying the manner in which the entity may create or add value. One of the concepts that give rise to several controversies is fair value. Even before 2007, the measurement of fair value had changed dramatically. We should also mention about fair value that it is more than a conventional measuring technique for its supporters, because there is an intolerable inconsistency of the mixture of measurement systems. Fair value is not in itself a unique measurement methodology, but it includes a variety of approaches for the estimation of an output value. In terms of utility, fair value represents in accounting a new basis for real production, which, as may be noted, is based on the economic and financial culture.

Consumer Behaviour in Time of Economic Crisis

Calin Mariana Floricica
"Tomis" University of Constanta
mariana_bentea@yahoo.com

Abstract

Given the ongoing changes occurring in the Romanian economy and the world as it is natural to modify consumer behavior. Those who suffer most from the crisis are those who do not want to change, to adapt.. Consumers are able to handle this difficult economic environment with a low salary, manage to buy from stores so that to get money until the next salary, made themselves certain things without being forced to buy them from stores. The disappearance of alternative forms of credit has hit consumer behavior VAT increase to 24% share is huge for a small economy and a depleted population, representing an extremely difficult factor to bear 25% lower wages brought to reorganize priorities and the default behavior of consumers.

Key words: consumer behavior, market strategies

J.E.L. classification: D12

Those who suffer most from the crisis are those who do not want to change, to adapt. And that has nothing to do with age.

Exchange rate stability, place of work are factors that determine a state of optimism, the hope that it will be better.

One important thing this year for companies is to remain grounded in market realities and macro level "close to customers and employees maintain. "

The stake will be the amount from any product. Consumers are more careful about what they buy. Must every manufacturer (brand) to earn a place in the consumer wallet.

Consumer behavior has been called into involution, marking a return to universal products as a result of buyers trying to find effective and affordable solutions in the context of a budget significantly reduced compared with 2007-2008.

We are talking about a dynamic and mature market, which includes products of first necessity, with a frequency of purchase, thus, quite high. The diversity category was sustained in recent years by launching more and more specialized products that benefit and diverse forms of use, which take place or come in addition to universal products.

Last year, the market has seen a decline in sales compared to same period in 2009. The phenomenon was due to the changes that have occurred in consumer behavior that have become more cautious in choosing the products look so price weighs heavily in the balance. The VAT increase to 24% of the state collected more money, but lost on the other hand, because tax evasion has increased, and living standards have fallen even more.

We add however, that the end of the year in the fourth quarter, the situation has improved and the market is back on an upward trend.

The offer was comparable to that in 2010, launching a lower rate, but with gratuitousness. These sales were made both by traditional communication media, and in stores. There is no disagreement when it comes to nominating the most effective marketing tool - promotional packages. Most often they relied on price promotions, free promotions because of financial difficulties during this period was found to be much more effective this type of marketing. The client is looking for added value or addition product, and both make it back and buy.

In any case, the use of promotions as a tool to boost sales has immediate results which are expressed according to manufacturers, in increments of 20-30% during that campaign.

Predicting the role it will play promotions in 2011, we can say that their number remains high, especially because all manufacturers are focused on building this shelf.

A particular problem was, the choice of shops near the house, or visit the supermarket? Lately finds a slight increase in sales of small and medium-sized shops. What fuels their sales?

There are a number of trends for the consumer contributing to increase in value the convenience sector, such as:

- increasing the number of households with one person;
- demographic factors;
- women's empowerment. Career women, but at the same time are wives or mothers, are among a segment of buyers who emphasized the need to purchase solutions in the vicinity of the house;
- missing meals. Studies show that more than a quarter of buyers (27%) did not eat breakfast, 19% more than in 2004, and the convenience sector will only benefit from this trend;
- lack of daily nutrition plan for a growing number of buyers.

Studying the profile of buyers from convenience stores, it was found that they acquire a wide range of products from basic to find gifts for special occasions or postal service. The ability to buy products from sites that can be reached on foot is what draws us to convenience stores.

Shopping completing basic products are obviously the main opportunity to visit, among buyers, mentioned by about 43% of those surveyed. One in six (17%) have also stated that in order to go refuel with fruit and vegetables. Respondents with higher household who took part in focus groups said they preferred way to purchase it just because it provides an additional degree of freshness. Therefore attention and managers of such stores has turned lately to modernize and streamline the supply chain.

In addition, assortment of the product was adapted to the needs of the communities in which they belong, moving away from standardized product offerings.

Following the purchasing behavior of consumers if the basis for food, specialized manufacturers say they have not thought about long-term usefulness of the product but were oriented to the detriment of small packets to the big weights. Exception is made where the item was on promotion, and then the acquisition price was justified by the reduced package. "People do not store quite as much as they used, because trying to spend less on shopping in one store visit. Thus, rather they buy small weights - 75 g envelopes - than the average, 250 g and 500g " Customers who have always shown an intensive ("heavy users") have remained loyal to favorite brands, and those who have an average consumer or small are more price-oriented promotions and therefore more unfaithful brands.

In the case of cubes - the basis for food, consumers have preferred packages with more units, one possible explanation being given by the product consistency component prepared foods, but especially the proportion of the unit cube. A special case in selling cubes - base stands for foods in traditional commerce. Marketing cubes, pieces remain important because of the low prices traditional commerce.

According to producers, over 90% of buyers are women with families, responsible for household food supply and who frequently use to cook a wide range of food. In terms of sales achieved, the most popular variety is the spice of universal category, due to extensive possibilities for use. Price promotions influence the purchase decision on the shelves. In addition, a series of intervening factors such as kinds of food, quantity, for a specific brand preference and price. Sales are equally influenced by the quality and price and supply in the background of the shelf and visual impact. For cubes, taste and preference for a brand influences purchasing decisions, but the segment is sensitive to promotional offers. Processed data provided by GfK Romania on sales volume category spices - the basis for food depending on the area of origin of consumer shows the following distribution:

Figure 1. Sales volume of spices geographically

Source: GfK Romania

The same study shows an increase in the consumption of more natural, organic and bio. The health care products containing preservatives as lower stands at the consumer level category.

Figure 2. Volume sales of natural products based on household income

Source: GfK Romania

What do the data GfK Romania spices consumer behavior in 2010 compared with 2009: In 2010 compared to 2009, household expenditure on food base category have increased significantly by about 9%, influenced mainly by the higher price paid. During this period there were no significant changes in buying behavior (approximately the same number of buyer households continue to make acquisitions in this category, on average once every two months).

Market database for foods is dominated by three manufacturers (Unilever, Nestle, Podravka), they cover more than three quarters of market value in the market despite the presence of a large number of buyers.

Delikat is the brand that attracts the largest number of households buyer. Romania households still prefer the version powdered spices (covering about three quarters of market value), the growing segment from 2009.

Contrary to patterns observed for the purchase of other consumer goods, traditional trade deal still an important part of the expenditure category. At the same time gaining ground in modern trade against the trend of traditional through to hypermarkets and discount stores, compared to the level registered in 2009. In the period January to December 2010, the share of modern retail in this category, as value was 49%. Traditional retail has dominated most of the sales in value, with a share of 51%.

Muntenia & Dobrogea is the region most households with the highest consumption of spices (representing 26% of the total and is responsible for the acquisition of 28% by volume). Also, those living in rural areas buy nearly half of the volume group. Great retailers in Romania have recorded catastrophic sales in first two months of 2011, amid rising prices and declining purchasing power of customers. Decrease in salaries, pensions and refusal of the 13th month were the main factors that have been added and others such as increasing fuel prices, which are found in transportation costs, practically in all prices and rising food prices internationally.

Unfortunately, the rack prices are leading more consumers to not reach out to those products.

Currently, the best selling products are very cheap, the sales, especially food. If fuel prices continue to rise, we feel all the effects, be it producers, distributors, customers. If we will have a rise of gas prices, freight rates, they will all come true in a carousel that will lead to further price increases.

According to the National Institute of Statistics, food prices raised in February 2011 with 8.83% and 7.27% non-food.

The food, the biggest price increases were recorded in the two months of 2011 to 10.34% potatoes (with 16.99% in the first two months of the year) for vegetables and tinned vegetables was recorded an increase of 7.98%. A significant increase was recorded in February and fresh fruit, which grows by 4.1% last month and 6.93% in first two months of 2011.

And bread significantly influenced inflation after prices grows by 2.3% to 2.9% in February and the beginning of the year. In food products, most were more expensive tobacco and cigarettes (1.44%). In contrast, price declines were noted in eggs, which were cheaper in February by 2.21%, cars and spare parts (-0.12%) or air transport (-0.39%).

Fuel price increased by 2.26% earlier this year. Further increases are expected due to fuel tensions in the world related to conflicts in North Africa.

If companies will increase salaries with inflation, people's purchasing power will decrease, which will negatively affect consumption. Moreover, because of inflation and rising costs for food or other goods, the

ability to save a portion of the population will decline.

Conclusions

Inflation, that charge "parse" as some economists call it, will strongly affect the purchasing power of Romanians in the next period, given that revenues will not be indexed by the rate of price increase. Economists warn that the biggest inflationary pressures coming from food and fuel prices.

Why the Tourist Chose the Romanian Coast

Calin Mariana Floricica
"Tomis" University of Constanta
mariana_bentea@yahoo.com

Abstract

The tourism potential is a key component of tourism, and a prerequisite of tourism development. Romanian seaside has always been an attraction for all ages and social categories. The main form of tourism is health tourism which is preferred by foreign tourists. In the last years, because invested in one resort, Mamaia, due to increasingly low levels of living of a large proportion of the population who prefer to come on the Romanian coast chose other destinations. The consumer's tourism has diversified their wishes. Looking at the prices offered by other tour operators, as well as possibilities for leisure, they headed by the Bulgarian coast, Turkey and Greece in particular.

Key words: tourism, Romanian seaside tourism offer.

J.E.L. classification: M20

Black Sea coastal area, known in the country and the world, has always attracted tourists, because he always has something to offer and maybe meet some of the motivations of people interested in tourism business: attractive landscapes, still unspoiled traditions, crafts and craftsmen, historical and cultural relics, diversity and quality dining, recreational opportunities, hunting, fishing, water sports etc..

Place and role of the Black Sea coastal area, is increasingly important with the development of rural tourism as an alternative to raising the living standards of inhabitants of these lands. From this perspective, the tourism potential of a territory can be defined in a general way, through all the elements that act as tourist attractions and facilities which are suitable for a visit and receive passengers. Tourism, more than any other

area of activity is dependent on the environment which is "the raw material", the purpose and scope of activity and development of tourism, which is its support frame, the carrier of its resources.

Romanian seaside is the most exploited tourist area of Romania. Romanian Black Sea coast stretches 245 km and is composed of Delta and coastal lakes, which amounts to a total length of 163 km and the beaches stretching over 82 km. Each year about one million tourists come to visit the Romanian coast. The sea in its action eroded and made the shore to pull up or by turning bays in estuaries and lagoons, or by abrasion of the right promoters. Cliffs, which represent two thirds of the length of coastline, have heights ranging between 20 and 40 m.

Considered a pearl of Romanian coast, is located on the cord of sand separating the sea salt waters of Lake Siutghiol freshwater. Mamaia beach is the largest Romanian seaside beach, with a length of 10 km - the hotel "Park" to "Pirate's Inn" - and a width varying between 100 and 200 m and 50-100 m from north to south. Tourism in Romania focuses on natural landscapes and its rich history, having also an important contribution to the economy. In 2006, domestic and international tourism has secured 4.8% of PIB and around half a million jobs (5.8% of total employment). After trade, tourism is the second important sector in the services sector. Romania's economic sectors, tourism is dynamic and ongoing rapid growth and is also characterized by a large potential for expansion. After *World Travel and Tourism Council* estimates, Romania ranked in the top four countries are experiencing rapid development of tourism, with annual growth of tourist potential of 8% from 2007 to 2016. Number of tourists raise from 4.8 million in 2002 to 6.6 million in 2004. Also in 2005, the Romanian tourism has attracted investment of 400 million Euros.

Figure 1. The number of tourists accommodated in Romanian seaside resorts

Source: NATA

In 2010, the Romanian coast attracted 1.8 million tourists, 15% fewer than in 2009. This was reflected in operators' revenues, which fell by 25%, according to NATA. The decrease in revenues was higher than the number of tourists that prices fell last year. Most popular were special offers at low prices. The number of Romanian tourists who preferred foreign destinations has remained constant this year compared to 2009, but earnings fell travel agencies. The most requested foreign destinations for the summer season this year were Bulgaria, Turkey and Greece, and amid substantial price reductions, the number of tourists who went to Antalya has doubled.

Romanian seaside, however, has not had the same performance as our neighbors. "While the weekends of high season (July 20 to August 20) stations were packed, the occupancy rate has been 50% during the week. Throughout the season, the Black Sea hotels were occupied for more than 60% ", according to NATA. One problem was that because of budgetary restrictions, the state has not passed any special offer launched by the agency. Regarding the number of foreign tourists preferred to spend his holiday on the Romanian coast grew by over 30% from 3,000 to about 4,000 people. Romanian tourists preferred the 2-3 star hotels and paid, on average, for a stay of five nights, between 500 and 800 lei in peak season.

For 2011, representatives of the NATA estimates that prices will stagnate or even to decline by 10% in the intermediate season (June 15-July 15 and August 15-September 1). This year, the Romanian seaside hoteliers offer several new services are included in

packages, such as the ability to pay for five nights accommodation to get seven, free access to swimming pool and lounge by the pool and on beach, free for children baby land, free accommodation for children younger than 12 years. According to the National Statistics Institute, the first 10 months of 2010, both arrivals and overnight stays in tourist reception with functions of accommodation were recorded decreases of 2.1%, respectively, of 8.6% over the same period last year.

A continuing problem of the Romanian seaside is that prices charged by the Romanian seaside hoteliers are higher than those in the resorts of Turkey and to a level close to those of people in Bulgaria, while the possibilities of fun and quality of beaches is lower.

Figure 2 Variation of the price accommodation for a stay of 7 nights

Source: NATA

In Romania

Comparing prices in high season packages that include lodging in a double room, so for two, but do not include transportation. Thus, in Mamaia, a stay of seven nights in three star hotel with half board, cost 650-750 Euros / double room. If you chose all-inclusive, it will reach 3000-3500 lei for a double room on seven nights.

Prices increased in 4-star hotels. It comes to 800 Euros per room, half board. All-inclusive version costs 3,800 lei / room, approximately 900 Euros for a stay of a week.

In Bulgaria

In Golden Sands, two people will pay for seven nights half board accommodation in 4 star hotel between 550 and 700 euros, while for all-inclusive price reaches 700-900 EUR. Prices are lower for the three-star hotels. For a stay of seven nights, half board, the price is 400-500 euro / double room, while for an all-inclusive packages to reach the 550-650 euro / double room / night.

In Turkey

And in the resort of Marmaris in Turkey are lower than the prices on the Romanian coast. In the case of a three-star hotel, a stay of seven nights half board reaches 380-450 EUR / double room. Those who opt for all-inclusive will pay 450-600 Euros for two people.

In the case of four-star hotels, prices will be the alternative of 500-650 Euros 700-850 Euros for half board and all-inclusive. Price differences are explained by the fact that Turkey has more resorts, and so competition is higher. There are many types of accommodations. On the other hand, in Romania 80% of the seaside tourist flow is ensured by the Romans, who will not go away from home.

And contributions on salaries, paid by Romanian hoteliers are higher than those paid by the Bulgarians. Then, because the price of utilities, food is more expensive in Romania than in Bulgaria or Turkey. Another factor influencing the differences between the three countries analyzed is the length of the tourist season as the Romans begin to blame the season after 15 June, when school holidays begin.

Remain uncovered when the season ends, even if hotels are open for Romanian and foreign tourists are not coming because they are not open terraces, shops, etc.. In an attempt to counteract the negative effects of the crisis were felt in the budgets of each novel have appeared in recent years all sorts of programs and attractive offers in terms of price.

Because 2010 brought dramatic declines in revenue Romans, many of them waiting for all programs and a week Black Sea, which makes NATA representatives to see in these initiatives a success.

Regarding the program 'Coast for all', it is the fourth year running. We compared prices at the new prices on all coasts and our neighbors are the lowest. The program is open to all, on the principle of first come first served basis. It is a program designed to stimulate circulation Romanian seaside, with no selection criteria.

There are open days holiday program in 15 to 31 August. After the needle passes the peak period, July 15 to August 15 tourists can pay to stay five nights and six, or pay 6 nights and stay 7 or 8. There are hotels even known. This year more than ever are special and diversified types of offers, which is a good thing in the hope that tourism will revive and so we could talk out of the crisis of this sector of activity.

Realizing SWOT analysis of tourism on the Romanian coast have emerged following elements:

Strengths:

- the natural attachment development of tourism activities
- high accommodation capacity, which is in full expansion
- tradition in tourist activities
- potential high health spa
- geographical position favorable to the development of new tourism products
- qualified and experienced human resources in tourism

Weaknesses:

- Insufficient parking places, in relation to the number of tourists during the summer;
- Lack of permanent tourist products
- lack of adequate infrastructure development of cruise tourism;
- Lack of a common long-term strategy for tourism investments and sustainable development of this sector blackened
- Promotional material available and fewer and fewer poor quality.

Opportunities:

- position at the confluence of three major geopolitical zones, creates the premises revaluation high tourist potential.
 - The possibility of developing new projects to develop the whole area interested
- Threats:

- lower interest for Romanian tourists travel products autonomous
- erosion of the beaches of carrying long can affect tourism development activities in this area.

The size and diversity of its elements, their value and originality, potential for tourism is the main motivation for tourist traffic. The correct evaluation of its components, assessing opportunities for their effective realization requires the establishment of a national and adequate categorical outline a coherent strategy to enable the development of tourism. Tourist attraction is the fundamental reason and the initial momentum of the movement to a

specific tourist destination. A zone or an area has interest to the extent that has elements of attraction which can lead to development of tourism activity.

Net Present Value Criterion - Important Factor in Validating the Efficiency of an Investment

Căruntu Constantin
Lăpăduși Mihaela Loredana
„Constantin Brâncuși” University,
Faculty of Economics and Business Administration
căruntu_ctin@yahoo.com, loredana@utgiu.ro

Abstract

The net present value has been and will remain one of the main criteria for selecting an efficient criterion. Financial theory has not referred to another more reliable criterion use selecting investment projects, rather than the maximization of net present value.

In general, the net present value means the surplus value resulting from the operation of an investment. This surplus (expressed in absolute terms) is the consequence of a comparison between the estimated effects generated by the analyzed investment and the effects that are judged to be obtained on behalf of investment alternatives.

The added profitability that will result from selecting and promoting investment projects superior to the investment on the money market, will lead to the increase of the company's value. The contribution of each investment project, to this additional value of the enterprise, is the net present value.

Key words: investment project, net present value, interest, investment money

J.E.L classification: D53, E22, G11

1. Introduction

Before investing one leu in any venture, one must know what will come out of every leu invested. While we take an investment decision, it is necessary to learn how to compute net present values, in order to obtain support for prudent investment decisions.

The net present value (NPV) is defined as the present values of cash flows less the amount invested and this updated if necessary. Net present value, as the name suggests, is nothing but a series of cash flows

emitted during the entire investment, expressed in present value.

Net present value takes into account both the positive and negative cash flows, meaning that it takes into account the investment made and the income generated.

NPV represents, increasingly more, a key criterion in dividing the investment projects. Thus, if through updating procedures it can update all expenses, revenues, future profit and compare them; this practically means applying the NPV rule.

As an evaluation method that takes into account the two sides of the investment activity, respectively the costs and benefits brought, the NPV makes a comparison between the cash flow released during the lifetime of a project (total and updated to time reference) and the investment effort (total, current value) involved in carrying it.

2. Body of the paper

Net present value (NPV) is one of the best financial instruments to establish the value of an investment project.

NPV criterion involves choosing from a series of investment projects, the one that has a maximum net present value. However, there are times when a project with a negative NPV is accepted because it constitutes a necessary premise for another project with a significant NPV.

From a financial standpoint, the investment represents the decision through which an actual certain amount is changed with future superior revenues with a certain level of probability.

In terms of monetary flows, the investment can be seen from four angles:

a) as one initial expense and one collection at the end of the period in which the investment takes place;

b) as a multiple expense, during the execution of the investment objective, and one collection, finally;

c) as one initial expense and multiple collections, during the execution;

d) as a multiple expense and multiple collections, during the execution.

NPV criterion is particularly important in any assessment of an investment. The major advantage of this method is that once the future cash flows are estimated and knowing, of course, the initial investment expense, calculations are very easy to be done. It is a quick and efficient method.

The net present value (NPV) of the project indicates the expected impact on the company's value, and the projects with a positive NPV are expected to increase this value. Thus, the rules regarding the decisions to be taken based on the NPV specify that all independent projects with a positive NPV should be accepted. If NPV is higher than zero, the project is acceptable because the revenues are sufficient to obtain a profit and to return the initial invested capital, before the end of the life of the investment. If NPV equals zero, the equilibrium is achieved at the end of life and the investment is much less attractive.

NPV is determined as the difference between the present value of the operation and the future resale of the investment (V_0), on the one hand, and the invested capital (I_0) on the other side. The net present value of the investment is calculated as the sum of future cash flows and discounted at the market interest rate $NPV = V_0 - I_0$. [8]

NPV criterion starts from the assumption, mentioned above, of an unsaturated money market: capitals (I) can be at any time reinvested on the money market, at the market interest rate (k), in order to obtain future cash flows (CF_t): [8]

a) for one year:

$$I_0 \cdot (1+k) \leq CF_1 + VR_1 \quad (1)$$

or

b) for $t = 1,2,3,\dots,n$ years:

$$I_0 \cdot (1+k)^n \leq \sum_{t=1}^n CF_t \cdot (1+k)^{n-t} + VR_n \quad (2)$$

From where:

a) for one year:

$$I_0 \leq \frac{CF_1 + VR_1}{1+k} \quad (3)$$

b) for $t = 1,2,3,\dots,n$ years:

$$I_0 \leq \sum_{t=1}^n \frac{CF_t}{(1+k)^t} + \frac{VR_n}{(1+k)^n} \quad (4)$$

where:

I_0 - initial investment expenses;

$\sum_{t=1}^n \frac{CF_t}{(1+k)^t} + \frac{VR_n}{(1+k)^n}$ - present value of future cash flows.

As the present cash flows (V_0) go higher than the invested capital, the investment project will be more efficient. [2]

NPV is calculated as the present value of the cash inflows minus the present value of cash outflows. This relationship is expressed by the formula:

$$\begin{aligned} VAN &= \sum_{i=1}^n \frac{CF_i}{(1+d)^i} = \\ &= CF_0 + \frac{CF_1}{(1+k)^1} + \frac{CF_2}{(1+k)^2} + \dots + \frac{CF_n}{(1+k)^n} \end{aligned} \quad (5)$$

where:

CF_i - net value of cash flows from year i ;

CF_0 - initial investment;

d - discounted rate;

n - number of years.

In the case of credited investments, NPV has to be higher than interest paid (interest which is usually recorded in operating expenses and not in the investments). To establish NPV at time zero we use the formula:[10]

$$VAN_0 = \sum_{t=1}^n CF_t \cdot (1+K)^{-t} - I_0 \quad (6)$$

where:

I_0 - discounted net investment at time 0.

At this moment there are carried out only the initial expenses (I_0), the investment begins to generate CF after starting the operation (considering the project period does not exceed 1 year). This criterion assumes that the annual cash flows (CF_t) are constantly reinvested in the financial market at the level of the discounted rate (K) which is unrealistic. [10]

If the discounted rate (K) varies from one period to another, VAN_0 becomes:

$$VAN_0 = -I_0 + \frac{CF_1}{(1+K_1)} + \frac{CF_2}{(1+K_1) \cdot (1+K_2)} + \frac{CF_3}{(1+K_1) \cdot (1+K_2) \cdot (1+K_3)} + \dots \quad (7)$$

It can be noted that a high discounted rate determines a lower NPV. Choosing the discounting rate is crucial for the reliability of the study.

To illustrate this we assume that a commercial company has resources to invest in an amount of 1.000.000 lei. It has to select from three projects by using the NPV criterion the best investment option.

The characteristics of the investment projects are in the following table:

project	Investment value CF ₀	Cash flows generated by the investment project – thousands lei				
		1	2	3	4	5
A	750	300	275	250	375	312,5
B	1.000	387,5	312,5	437,5	375	350
C	625	150	300	250	325	262,5

For all the projects, the discounted rate which corresponding to the growth option of the company is 12%.

It will be determined the NPV for all three investment projects.

We use the synthetic general formula of computing the net present value:

$$VAN = \sum_{i=1}^n \frac{CF_i}{(1+d)^i} - CF_0 \quad (8)$$

►Project A

We determine the discounting factors:

- year 1: $\frac{1}{1+12\%} = \frac{1}{1,12} = 0,8929$ (9)

- year 2: $\frac{1}{(1+12\%)^2} = \frac{1}{1,12^2} = 0,7972$ (10)

- year 3: $\frac{1}{(1+12\%)^3} = \frac{1}{1,12^3} = 0,7118$ (11)

- year 4: $\frac{1}{(1+12\%)^4} = \frac{1}{1,12^4} = 0,6355$ (12)

- year 5: $\frac{1}{(1+12\%)^5} = \frac{1}{1,12^5} = 0,5674$ (13)

We determine the discounted values:

- year 1: $300 \cdot 0,8929 = 267,87$ (14)

- year 2: $275 \cdot 0,7972 = 219,23$ (15)

- year 3: $250 \cdot 0,7118 = 177,95$ (16)

- year 4: $375 \cdot 0,6355 = 238,3125$ (17)

- year 5: $312,5 \cdot 0,5674 = 177,3125$ (18)

$$VAN = \left(\frac{267,87 + 219,23 + 177,95 + 238,3125 + 177,3125}{(1+12\%)^1 + (1+12\%)^2 + (1+12\%)^3 + (1+12\%)^4 + (1+12\%)^5} \right) - 750 = 1.080,675 - 750 = 331 \text{ thousands lei}$$

or

$$VAN = \sum_{i=1}^5 \frac{CF_i}{(1+d)^i} - CF_0 =$$

$$\left[\frac{300}{(1+12)^1} + \frac{275}{(1+12)^2} + \frac{250}{(1+12)^3} + \frac{375}{(1+12)^4} + \frac{312,5}{(1+12)^5} \right] - 750 =$$

$$\left[\frac{300}{1,12} + \frac{275}{1,2544} + \frac{250}{1,4049} + \frac{375}{1,5735} + \frac{312,5}{1,7623} \right] - 750 = 1080,681 - 750 = 331 \text{ thousands lei}$$

►Project B

We determine the discounting factors:

- year 1: $\frac{1}{1+12\%} = \frac{1}{1,12} = 0,8929$ (21)

- year 2: $\frac{1}{(1+12\%)^2} = \frac{1}{1,12^2} = 0,7972$ (22)

- year 3: $\frac{1}{(1+12\%)^3} = \frac{1}{1,12^3} = 0,7118$ (23)

- year 4: $\frac{1}{(1+12\%)^4} = \frac{1}{1,12^4} = 0,6355$ (24)

- year 5: $\frac{1}{(1+12\%)^5} = \frac{1}{1,12^5} = 0,5674$ (25)

We determine the discounted values:

- year 1: $387,5 \cdot 0,8929 = 346$ (26)

- year 2: $312,5 \cdot 0,7972 = 249,125$ (27)

- year 3: $437,5 \cdot 0,7118 = 311,4125$ (28)

- year 4: $375 \cdot 0,6355 = 238,3125$ (29)

- year 5: $350 \cdot 0,5674 = 198,59$ (30)

$$VAN = \left(\begin{array}{l} 346 + 249,125 + \\ + 311,4125 + \\ + 238,3125 + 198,59 \end{array} \right) - 1.000 = \quad (31)$$

$$= 1.343,44 - 1.000 =$$

$$= 343,44 \text{ thousands lei}$$

or

$$VAN = \sum_{i=1}^5 \frac{CF_i}{(1+d)^i} - CF_0 =$$

$$\left[\begin{array}{l} \frac{387,5}{(1+12)^1} + \frac{312,5}{(1+12)^2} + \\ + \frac{437,5}{(1+12)^3} + \\ + \frac{375}{(1+12)^4} + \frac{350}{(1+12)^5} \end{array} \right] - 1.000 =$$

$$\left[\begin{array}{l} \frac{387,5}{1,12} + \frac{312,5}{1,2544} + \\ + \frac{437,5}{1,4049} + \\ + \frac{375}{1,5735} + \frac{350}{1,7623} \end{array} \right] - 1.000 = \quad (32)$$

$$= 1.343,44 - 1.000 =$$

$$= 343,44 \text{ thousands lei}$$

►Project C

We determine the discounting factors:

- year 1: $\frac{1}{1+12\%} = \frac{1}{1,12} = 0,8929 \quad (33)$

- year 2: $\frac{1}{(1+12\%)^2} = \frac{1}{1,12^2} = 0,7972 \quad (34)$

- year 3: $\frac{1}{(1+12\%)^3} = \frac{1}{1,12^3} = 0,7118 \quad (35)$

- year 4: $\frac{1}{(1+12\%)^4} = \frac{1}{1,12^4} = 0,6355 \quad (36)$

- year 5: $\frac{1}{(1+12\%)^5} = \frac{1}{1,12^5} = 0,5674 \quad (37)$

We determine the discounted values:

- year 1: $150 \cdot 0,8929 = 133,935 \quad (38)$

- year 2: $300 \cdot 0,7972 = 239,16 \quad (39)$

- year 3: $250 \cdot 0,7118 = 177,95 \quad (40)$

- year 4: $325 \cdot 0,6355 = 206,5375 \quad (41)$

- year 5: $262,5 \cdot 0,5674 = 148,9425 \quad (42)$

$$VAN = \left(\begin{array}{l} 133,935 + 239,16 + 177,95 + \\ + 206,5375 + 148,9425 \end{array} \right) - 625 = \quad (43)$$

$$= 906,525 - 625 =$$

$$= 281,525 \text{ thousands lei}$$

or

$$VAN = \sum_{i=1}^5 \frac{CF_i}{(1+d)^i} - CF_0 =$$

$$\left[\begin{array}{l} \frac{150}{(1+12)^1} + \frac{300}{(1+12)^2} + \\ + \frac{250}{(1+12)^3} + \\ + \frac{325}{(1+12)^4} + \frac{262,5}{(1+12)^5} \end{array} \right] - 625 =$$

$$\left[\begin{array}{l} \frac{150}{1,12} + \frac{300}{1,2544} + \\ + \frac{250}{1,4049} + \\ + \frac{325}{1,5735} + \frac{262,5}{1,7623} \end{array} \right] - 625 = \quad (44)$$

$$= 906,525 - 625 =$$

$$= 281,525 \text{ thousands lei}$$

Although each of the investment projects recorded a positive net present value, the company will have to opt for project B because it generates the maximum net present value.

If the company has as an objective the profit maximization, the projects should be undertaken only if their NPV is higher than the opportunity cost.

An investment analysis requires the definition of input data and key variables behind the cash flow structure, which involves understanding the changes that result from decisions, regardless of the accounting methodology, tax adjusted and integrated into the economic life. The economic analysis of the investment decisions should be based on differentiation of income and expenditures, in the form of flows caused by the decision, and not of changes due to accounting policies. [6]

3. Conclusions

- Net present value recognizes the time value of money principle; it allows comparing the investment effort from the present time, respectively the opening of the project that is a value to date with an investment effect, respectively future cash flows discounted at a rate that expresses the opportunity cost of the invested amounts.
- Net present value allows the decision maker to pursue investment throughout its life cycle and does not provide only a picture at a time, as the accounting methods do.
- Net present value evaluates the investment as the shareholders do, given the importance of opportunity costs of invested capital.
- Net present value captures all cash flows in a single rate and lends itself to computer modeling, allowing for sensitivity analysis.
- Net present value respects the adding value principle, an important rule which allows the analysis of investment packages and even of the entire company.

To justify an investment, the NPV has to be positive and higher than the compounded interest, received from the capital market. As the NPV increases more, the project becomes more profitable, and if NPV is negative, CF does not allow rebuilding the initial allocated funds and the project should be rejected.

The main measures of the investments are designed to take into account the temporal scope of cash inflows and outflows related to the investment, in relation to the economic attractiveness and compared to the expectations regarding the profitability. Creating added value for the shareholders through a higher profitability than the cost of capital is the key criterion of investment analysis, net present value and the internal rate of return being able to be used in testing analytically this result. A Hybrid Architecture For Context-Aware Systems

Chelai Ozten

„Ovidius” University of Constanta, Faculty of Mathematics and Informatics
ocheai@univ-ovidius.ro

Abstract

Today applications give us complex services in behalf of the user no matter of location, time or hardware infrastructure. There is a growing realization that computer systems will need to be increasingly sensitive to their context. That is, the application can decide what to do, based not only on the explicitly presented input, but also on the context, and its result can affect not only the explicit output, but also the context. This paper describes the need for an extensible context framework with embedded features. A hybrid (symbolic/connectionist) architecture is proposed. It consists of a multitude of agents having both a symbolic and a connectionist part. The symbolic part represents some knowledge structure, while the connectionist part represents its relevance to the current context. The performance of the system emerges as a result of the work and interaction of the currently active agents, where the set of active agents is not predefined for a specific task but is dynamic and reflects the specific context.

Key words: context-aware systems, computer systems architecture, software agents.

J.E.L.classification: C8, C89

1. Introduction

The progress in hardware and software technologies permits to develop more intelligent applications at macroscopic level.

Moreover the complexity of industrial applications demands such kind of onset. The need of integrating the researching made in the computers and control field is obvious.

The computation is made at a high level of abstraction, almost human and the architecture that specifies the underlying

infrastructure is very important.

In this context the paper presents an architecture that combines both advantages given by the distributed autonomous architectures and centralized architectures in a generic control system.

The system is based on blackboard model and uses agent technology in a distributed environment.

Today applications give us complex services in behalf of the user no matter of location, time or hardware infrastructure. There is a growing realization that computer systems will need to be increasingly sensitive to their context. Traditionally, hardware and software were conceptualized as input/output systems: systems that took input, explicitly given to them by a human, and acted upon that input alone to produce an explicit output. Now, smart computers, intelligent agent software will have to operate on data that are not explicitly given to them, data that they observe or gather for themselves. These operations may be dependent on time, place, weather, user preferences, or the history of interaction. In other words, context. Laptops, Notebooks, PDAs, smart phones and other devices have already freed us from the workstations and desktops. Large scale experimental computing “clouds” and “grids” have provided service to an extraordinary number of computer users. The accent is on “giving the right thing at the right moment”. For this the context is important. That is, the application can decide what to do, based not only on the explicitly presented input, but also on the context, and its result can affect not only the explicit output, but also the context. Any given context may include information about the physical world (location, movement, temperature, pressure, device characteristics, and so on) and about the logical world surrounding the service consumer. Even historical information about any of these aspects might be included. Context can be considered to be everything

that affects the computation except the explicit input and output.

This paper describes the need for an extensible context framework with embedded features. A hybrid (symbolic/connectionist) architecture is proposed. It consists of a multitude of agents having both a symbolic and a connectionist part. The symbolic part represents some knowledge structure, while the connectionist part represents its relevance to the current context. The performance of the system emerges as a result of the work and interaction of the currently active agents, where the set of active agents is not predefined for a specific task but is dynamic and reflects the specific context. So particular symbolic operations and data structures may be supported or suppressed depending on the particular activation pattern of the connectionist parts which represent the context-dependent relevance of the operations and structures. In this way a context-sensitive computation emerges.

The paper has four sections: Introduction, Related work, A context-aware architecture, and Conclusions. The first section presents context sensitive systems and their characteristics. Related work section summarises context architecture research which has been published before. The context-aware architecture section includes technical description of structure of context architecture and possible applications. Finally, Conclusions section presents technical capabilities of the architecture.

2. Related work

Context control is necessary in all applications. Applications are complex, platform independent and intelligent. To manage complex applications a modular approach is needed and an important aspect is the architecture of the applications. The modular applications are loosely coupled or autonomous. It is obvious that each component has to self control its behavior. The intelligent behavior refers also to self control without an explicit action of the user. So, context-aware characteristic is implied.

To be platform independent, applications don't manage directly their resources or they specify the needed resources using a universal standard.

Context-aware systems are able to adapt their operations to the current context without explicit user intervention. The context-aware feature is needed in today systems that have pervasive (ubiquitous) characteristics. The goal of researchers is to create a system that is pervasively embedded in the environment, without any explicit resource management, completely connected, intuitive, portable, and constantly available. Context aware systems are suited in all today applications.

Although new technologies are emerging, the most crucial objective is not, necessarily, to develop new technologies, but on finding ways to integrate existing technologies with existing infrastructures and give user best tools on an existing context. For example Carnegie Mellon University's Human Computer Interaction Institute (HCII) is working on a research in their Project Aura, whose stated goal is "to provide each user with an invisible halo of computing and information services that persists regardless of location." The Massachusetts Institute of Technology (MIT) has a project called Oxygen. MIT named their project after that substance because they envision a future of ubiquitous computing devices as freely available and easily accessible as oxygen is today.

In the literature there were several surveys on context-aware system architectures and for us the most significant ones are the following: Beldauf et al. [1] proposed a survey of a good number of architectures and Moeiz Miraoui et al. give us an excellent survey of context-aware systems in pervasive computing environment [2].

The Active Badge project [3] developed by Olivetti Research Ltd. aims to built a system for phone calls delivery according to the called person's localization. The architecture is layered and has four layers: the network controller which supervises the operation of the sensor network, the information presentation which is responsible for data management and control of localization information, the data processing which selects the interesting information at the time of localization variation, the user interface to display the textual information about badges variation position. Another example is The Xerox project ParcTab [4] with a material infrastructure that enhances the development of applications aware to

localization context (person location, surrounding devices, nearby people, etc.). The stick-e-notes project [5] is a framework to support the development of context-aware application where localization is the basic component of context. In this system the main component is a personal digital assistant (PDA) connected to a localization sensor. The idea behind the stick-e-notes comes from stick notes used to remind user about something (or to briefly describe something). These architectures are dependent on hardware. The CASS tool [6], CORTEX framework, Biegel et al. [7], context toolkit [8], Hydrogen [8], CoBrA [9] are layered architectures for context-aware systems that support the development of context-aware applications in an intelligent space. Most of the architectures make distinction between context sensing processes from its use. This permits an abstraction of low level sensing details and increases the extensibility and reusability of architecture components. Most of these architectures are layered and composed of the following components:

- sensor (physical sensing of contextual information),
- interpretation: transformation of information into a more significant and useful information,
- reasoning: (not present in all architecture) deduces and predicts new contextual information,
- storage and management: basic operation in managing contextual information (add, remove, research, update, etc.)
- adaptation: adaptation of provided services according to the current context.

3. The context-aware architecture

A context-aware environment has some specific characteristics. Context-aware system has to perceive contextual information. Software architecture must hide the complexity of the devices by providing a higher level of abstraction which makes it independent of the devices and enhances the reusability of architecture components.

Context aware systems have to adapt to the current context without an explicit intervention from the user and for this is have to have proactive devices. This requires that

devices embed a reasoning mechanism in order to take initiatives for a correct adaptation. For this the devices must be autonomous, independent from each other and easily connected.

A context-aware system has to be flexible and used in different environments. So that devices can be added or removed dynamically without affecting the entire operation of the global system (hardware extensibility).

Context-aware architecture should provide reusable components in order to ease their integration and reduce development effort. To have an extensible and reusable software architecture a higher level of abstraction is needed.

To be proactive an interpretation module and a reasoning mechanism is needed.

Software architecture must hide the complexity of the physical devices by providing a higher level of abstraction which makes it independent of physical devices and enhances the reusability of architecture components.

A context-aware system is composed of proactive devices that adapt to the current context without an explicit intervention from the user. This requires that devices embed a reasoning mechanism in order to take initiatives for a correct adaptation.

The architecture have to make an abstraction of contextual information in order to be hardware independent.

The necessary components of the architecture, for each type of context, are:

- devices equipped with sensors to perceive context variation and send them to the server without local processing;
- a database to store the data;
- a module for context interpretation to obtain a higher level of abstraction;
- a module for reasoning that give the proactive and self control characteristic.

Extending the existing architectures, the architecture has to have two interfaces:

- Sensor of events perceived by sensors (sensor or consumer);
- Event emission to adapt to the current context (actuator or producer).

The communication uses the mechanism based on events which are established dynamically during the system operation.

Architecture dominates mechanism [10], i.e. global design determinates global capabilities such as perception, planning, goal management and action. The lowest level modules simply gather sensor information from a data acquisition card (sensory processing) and implement simple single-loop feedback control algorithms in response to the evaluation of the problem or command coming from higher levels. They may also maintain a model of the physical subsystem they are controlling (a world modelling structure that contains more detail but at a smaller scale than the higher modules). Higher level modules may incorporate long-term planning and evaluation in the behaviour generation and value judgment operations. A significant concern with complex systems is the communication between modules. Communications set the infrastructure for intelligent and complex designs. Since high-level commands are decomposed throughout the levels, it is necessary for higher modules to pass commands to lower modules so that tasks can be carried out. Furthermore, for system modelling purposes, long-term planning, and fault detection, it is necessary for lower modules to be able to communicate status information to those at the higher level.

Context-aware is characterized by event-driven operations: system activities are driven largely by interrupts coming from sensors that are bound to specific functions, which transform the sensor signal into a series of signals to the control devices. Often context-aware systems, and their data management subsystems, must be highly available, because they control real-world processes. The key performance requirement is guaranteed maximum response time under peak load at least for the functions of high priority—otherwise something might crash or explode or expire. Therefore, context-aware systems—and the real-time databases underlying them—must be able to do deadline scheduling. In a typical context-aware system incorporating a real-time database, each device detects the values of some attributes of the real world and makes them available to the database. In turn the database provides the information needed by various system transactions to perform their functions.

Designing a control algorithm based only on isolated conventional control methods will not suffice to achieve autonomous or even proper operation of a large control system that needs to perform many complex tasks in real time. For such control systems it may be difficult or even impossible to develop an analytical model that describes the overall operation. For many years researchers have been trying to develop a systematic approach for design and implementation of these types of control systems. The usual approach for overcoming the complexity is to break down the problem to smaller and easier to solve sub-problems (and conventional control approaches are sometimes quite useful for these). The resulting control algorithms often use a "hybrid" or coordinated combination of control methods and address the control of both the continuous and discrete-event components of the plant. This has led to the introduction of several functional architectures that integrate a variety of methods to try to achieve autonomous operation. In general, these architectures have a hierarchical structure and provide coordination of the physically distributed subsystems to achieve system-wide goals.

Challenging practical issues surround the implementation of complex real-time control systems. One example is the development of communications between multiple, separately operated subsystems whose behaviour may be interdependent. Moreover, different subsystems may be running on different and incompatible platforms making the problem even more difficult. It is desirable to develop a control algorithm which is system independent, so that it can be operated on different computer hardware and software.

The other possible solution is the use of blackboard architecture. A blackboard provides all agents with a common area in which they can exchange information, data and knowledge. Agents initiate communication by writing their information towards the blackboard and all other agents can always access the blackboard to see if new information has arrived. No direct information exchange between agents takes place in the blackboard system. Every agent solves its own problem based on information from sensors and the blackboard.

The design of a multi-agent system requires flexible autonomy. Meaning that agents will be required to work autonomously, but will often be influenced by others. A central control system will not be used, as an autonomous system with central control in a dynamic environment is rather difficult to realise and decentralised control systems seem to be more robust. Furthermore, global optimisation is a relative subject in a changing environment and robustness is of equal importance. To get a balance between performance and complexity a hierarchical architecture based on semi-autonomous agents seems to be the solution. Each layer has its own optimisation view and may help solve conflicts of lower level agents.

The proposed architecture is based on a structured approach, which allows the designer to apprehend the complexity of great systems using a modular and hierarchical specification. The design of the structuring model proceeds from the subdivision of the physical process into groups forming an n-ary tree. A node is an entity. In the same level, entities are grouped within a parent entity of superior level, forming a parent-children relationship. Entities can communicate only with their parent entity or use the services given to them by their children entities. This tree structuring has a lot of benefices for entity access and data. Once the hierarchical architecture is defined, the structuring model is resumed in a top down way, to analyze, specify and describe the content of each entity. This structuring highlights the whole knowledge (data, processing, control, storing, etc.) concerning the functioning of each entity as well as its interaction with the other entities. The architecture of the control/monitoring system is organized in hierarchical entities. Each entity corresponds to a well defined subset of the system which controls and monitors at a given abstraction level. Essentially, the blackboard model provides a high-level abstraction of knowledge and solution techniques for dynamic control and allows use of the knowledge for opportunistic and incremental problem solving. Any change in the solution state, generated by an event, either due to generation of additional information or

modification of existing information is immediately recorded in the blackboard. The controller notes this change and takes necessary actions by invoking an appropriate knowledge source.

The multi-agent approach allows a set of agents to cooperate between themselves in order to resolve a problem. Hence, each agent can execute one or more tasks. To achieve these tasks, an agent must be autonomous. This approach is particularly adapted to manage complex systems by favouring the clarity and the consistency without neglecting the modularity and hierarchy. A multi-agent system is a group of agents, which co-operate to solve a problem that cannot be efficiently cleared up on an individual basis. The definition of each control/monitoring entity will be done in such a way that it will be sufficiently autonomous and have enough expertise to carry out its task(s). An entity (agent) will be able to communicate with the other entities to share some knowledge, to ask services or to inform about its plans or decisions

4. Conclusion

Context awareness is an important feature of today software applications. In this paper were presented relevant context-aware architectures. Most architectures are layered which allows the separation of context acquisition and context use in order to increase the level of context abstraction and hide the physical sensing complexity. This enhances both reusability and extensibility of the system. In order to offer proactive systems, architectures embed a reasoning system to ease adaptation task. The proposed architecture it is not specific to an application domain (localization systems, human-computer interaction, etc.) and require additional effort for their adaptation. Architectural design of context-aware systems needs more efforts in order to provide an appropriate architecture that suits more general system requirements.

Regional Development Policy in European Union

Abstract

The regional development policy is one of the most important policies and one of the most complex in the EU, as its status is derived from its goal of reducing the economic and social gaps existing between different regions of Europe and it influences different domains that are important for their development, such as economic growth and small and medium enterprises (SME) sector, transports, agriculture, urban development, environmental preservation, employment and professional training, education, gender equality.

Designed as a solidarity policy at European level, the regional policy is basically based on financial solidarity, namely on redistributing some parts of the Community budget made up of the contributions of the Member States to the less prosperous regions and social groups (between 2000-2006, the due amount is approximately one third of the EU budget).

Key words: regional policy, sustainable development, financial instruments, European cooperation, regional competitiveness

J.E.L. classification: Q01, R11

1. Introduction

The regional development policy is highly instrumental and through its solidarity funds it contributes to other sector policy financing – agricultural policy, social policy, environmental preservation policy. In addition to this, the regional policy is correlated with the expansion policy of the EU, by creating special funds of pre-accession such as PHARE (a support fund for the economic reconstruction), ISPA (a tool

for structural policies which anticipates the Cohesion Fund) and SAPARD (a special programs for agriculture) which are accessible for the countries applying for accession and support their transition to the EU organizational structure and standards. The complexity of the regional development policy is also underlined by the manner in which it integrates three of the EU main goals: economic and social cohesion, the expansion of the subsidies principle and sustainable development.

2. Regional policy of the European Union

Not only that the economic and social cohesion is to be found at the structural funds objectives level, but its importance is also reflected by the creation of an homonym fund (the Cohesion Fund) which supports the acceleration of the convergence process and the reaching of a medium level development of the EU, of four less developed Member States: Spain, Portugal, Greece and Ireland. The subsidies principle [1] – which represents the high degree of involvement from the Member States in the development and implementation of the Community policies - is also to be found at other policies level. In the present context, this principle is applicable in every state's financing negotiation for the solidarity funds (according to the national and regional priorities) and in their responsibility as to the implementation, monitoring and evaluation of the commonly agreed programs. The strategy of sustainable development represents a priority of the European solidarity programs, by particularly emphasizing the environmental protection and by developing adequate measures. This strategy is not just European but also global and it is promoted worldwide through various

international agreements, thus underlining the complexity of the regional development policy and the internal coherence of the communitarian objectives.

Considering its enlargement, the regional development policy applies to several fields of activity, and leads to the implication of many institutional participants in its design and implementation. [1] The European Commission is directly responsible for the preparation and implementation of the EU's regional development policy. Its role is to initiate and complete new specific legislative acts and to ensure that the adopted measures will be implemented by the Member States. The Directorate-General for Regional Policy is the main responsible department for the assistance measures regarding the economic and social department of the European regions, based on the articles 158 and 160 of the EU Treaty. The Directorate-General for Regional Policy is supported in its activities by other directorates general involved in the implementation of the regional policy, such as The Directorate-General for Agriculture, The Directorate-General for Fisheries, The Directorate-General for Education and Culture, The Directorate-General for Environmental Affairs and The Directorate-General for Employment and Social Affairs. Currently, The Directorate-General for Regional Policy manages 3 funds: FEDR, the Cohesion Fund and ISPA. [2]

The European Parliament is involved in decision-making for the Community regional development policy, through its Committee for Regional Policy, Transport and Tourism. Also, this committee exerts control over the implemented tools in order to achieve the objective of economic and social cohesion and implicitly over the national economic policies, the Community policies and actions in order to achieve the objective of an internal market, and over the Structural Funds, the Cohesion Fund and the European Investment Bank. The Council of the EU is the equivalent of a council of ministers at the European level and it gathers several times per year in order to coordinate the economic policies of the Member States. The Committee of the Regions is a consulting-authority for the problems concerning the economic and social cohesion, Trans-European infrastructure networks, healthcare,

education, culture, employment, social issues, environmental affairs, professional training and transport, being the newest European institution (established in 1991, under the Maastricht Treaty, came into force in 1993). The Committee of the Regions is composed of representatives of regional and local governments and it reflects the politic, geographical and local/regional balance of every Member State.

The European Investment Bank is the financing institution of EU policies and it has two tasks, as an institutional participant in the regional development policy and as a financing and implementation authority. The Bank grants loans and guarantees, at a small interest, to all Member States, financing projects in all the economic sectors, supporting through its actions the regional development policy at the Community level, the structural funds objectives and of other financial instruments in EU.

While the economic progress took place in less developed regions on medium term, the difference between the rich and the poor remained as concerning as ever, this situation calling for a considerable period of time in order to be solved. Despite this improvement, the unemployment is still an urgent issue.

Although an important progress of infrastructure has been achieved, some imbalances still exist in some areas: technological research and development, access to training and information, educational opportunities, environmental quality. The Structural Funds and the Cohesion Fund have helped in reducing the disparities and have created conditions for the economic growth. The Regional Policy contributions can be hardly depicted in statistical terms. The Community initiatives, the involved parties' partnerships, the emphasis on environmental preservation and equal chances, the cooperation, the improved communication due to the new technologies, the experience exchanges and the experience of new development approaches - they all represent premises for the progress of less prosperous regions and for their potential exploitation.

3. The European Union Financial Instruments – Background

The principles of regional development policy were drawn at the European level, starting with 1957, under *the Treaty of Rome*, when 6 signatory countries (Belgium, France, Western Germany, Italy, Luxembourg and Netherlands) established the necessity to reduce the existing differences between different regions and to support the less favoured ones, with the aim to achieve a solid and unitary Community economy.

This necessity was addressed in 1958, when *the European Social Fund* (ESF) was established as the main instrument of the Community social policy, being centred on the improvement of the labour market functionality in different countries and on the re-integration of the unemployed on the labour market. [2]

In 1962 *the European Orientation and Agricultural Guarantee Fund* (EOAGF) was established, with the aim to finance the common agricultural policy, to support the rural regions development and to improve the agricultural structures.

In 1975 the third fund was set up – The European Regional Development Fund (ERDF) with the task to redistribute some of the budgetary contributions of the Member States to the poorer regions of the Community, in order to support their economic development. Thus, ERDF redistributes the Community budget for productive investments (in order to create and safeguard sustainable jobs) and for infrastructure investments.

An important moment for the regional development policy evolution was the *Single European Act* (SEA), in 1986, which emphasized the concept of economic cohesion – that is to remove the existing economic differences between different regions – and created the premises for a specific policy of economic and social cohesion with the aim to facilitate the access to the single European market for the Southern Europe countries.

In February 1988, the Council of Europe in Brussels expands the solidarity funds operation represented by the previously

mentioned funds and currently known as *Structural Funds*- and it significantly increases their allotments to the Community budget. Thus, the importance of these instruments is the reduction of the regional disparities at the Community level.

In setting the regional policy, the PHARE programme, established in 1989, was a novelty designed to support Poland and Hungary (recently emerged from the communist regime) in their national economies reconstruction effort. Its revising, in 2000, was designed to support the regional development of the countries applying for accession.

With the ratification of the *Treaty of the European Union* in 1993, the issue regarding the economic and social cohesion is again set on the Community agenda and becomes one of the main objectives for the EU, alongside with the economic and monetary union and the single European market. It also leads to the creation of a new fund – *The Cohesion Fund*, which has the aim to support the projects of the environmental preservation and transport infrastructure areas in the less developed Member States (Spain, Portugal, Greece and Ireland). [2]

In 1994, a new structural fund is set up, the fourth one – *Financial Instrument for Fisheries Guidance* (FIFG), established by grouping all the Community instruments regarding fisheries that existed at that moment. FIFG was created to facilitate the Northern enlargement of the EU, with the adherence of Finland and Sweden in 1995. In the same year, *the Committee of the Regions* becomes active – a consulting-authority established under the Treaty of Maastricht with the aim to participate in the decision-making process and to support the European Commission in its regional development sector activities.

The Treaty of Amsterdam (1997) acknowledges the importance of the economic and social cohesion policy and of the reduction of differences between various European region living standards, thus emphasizing the necessity of corroborated actions in reducing the unemployment.

The reform of the structural funds takes the same direction that began in 1999 following the Berlin Summit, in which new rules of functioning were established. The

reform has the aim of increasing the Community assistance focus through these funds, alongside with their administrative simplification and decentralization. The reform brought a novelty with the complementation of the PHARE programme with other two instruments for the pre-accession – ISPA (Instrument for Structural Policies for Pre-Accession) and SAPARD (Special Accession Programme for Agriculture & Rural Development), which promote the economic and social development of the countries applying for accession from the Central and Eastern Europe.

A new solidarity instrument was established in 2002, subsequent to the major flooding in the Central Europe, *The European Union Solidarity Fund* with the aim to intervene in the major natural disasters that have serious repercussion over the living conditions in the affected regions, over the environment and their economies.

4. The financial instruments of the regional policy

Between 2007 and 2013 one third of the EU budget (approximately 840 billion EUR) will be allocated to the cohesion policy, which will be financed by three financial instruments:

1. *European Regional Development Fund (ERDF)* – aimed to reduce the disparities between different regions of the EU. It is the most important structural fund in terms of resources, granting financial aids to poorer regions, thus being an instrument of correction for the regional disparities. The principles of fund allocation are: to focus on objectives and regions (in order to maximize the effects), the partnership between the European Commission, the Member States of EU and local and regional authorities (in order to plan and to implement the structural intervention), to plan the intervention and the extra contribution of the Community (which must not replace the national one). ERDF must participate in the increase of economic and social cohesion and in the regional disparities reduction, by supporting the structural development and adjustment of the regional economies, including the conversion of regions of industrial decline and of the

poorer regions, to the cross-border, transnational and inter-region cooperation.

For this purpose, ERDF will support the Community priorities, particularly the increasing competitiveness and innovation, the creation of jobs on long term and the sustainable development.

2. *European Social Fund (ESF)* – the main instrument of the social policy of the European Union. Its aim is to finance the training and professional reconversion actions and the creation of jobs. ESF must participate in achieving the Community priorities concerning the economic and social cohesion, in ensuring a high degree of employment and many and better workplaces, by improving the job prospects. This will have to support the national policies regarding a complete employment degree, the quality ensurance and labour productivity and to promote social integration, by ensuring access of unfavoured categories to the labour market and by reducing the national and regional disparities.

3. *The Cohesion Fund* – contributes to the strengthening of social and economic cohesion of the Community, in order to promote a sustainable development. It finances projects in the following areas: environmental, such as renewable energy sources that lead to sustainable development; Trans-European networks, particularly projects of European interest.

The cohesion policy is financed by the EU budget with 3 structural instruments: European Regional Development Fund (ERDF), European Social Fund (ESF) and the Cohesion Fund (CF). These three financial instruments finance the following objectives[3]:

A. *The first objective. The convergence objective.*

It focuses on the NUTS II regions, having a GDP (gross domestic product)/capita smaller than 75% of the Community average. The financial allocation for this objective has increased to approximately 81,54%, 251,163 billion EUR of the cohesion policy allocation. Other eligible participants are the Member States that have a GDP (gross domestic product)/capita of less than 90% of the Community average. This objective aims to accelerate the economic development of the less developed regions by investing in

infrastructure, in people, innovation and in knowledge society and environmental preservation.

B. The second objective. The regional competitiveness and employment.

The regions that benefit from the financing for this objective are those which are not eligible to receive funds for the convergence objective. This objective is financed solely by the structural funds, such as ERDF and ESF. The financial allocation is of 15.95% of the cohesion policy budget and it sums up 49.127 billion EUR for the financial period between 2007 and 2013. The actions that can be financed for this objective are those concerning the development of the competitive regions, the employment by anticipating the economic and social shifts, by raising and improving the quality of investment in people, innovation and by promoting the informational society .[3]

C. The third objective. European territorial cooperation

This objective's aim is to increase the cooperation between regions at three levels: inter-region cooperation – to encourage the experience exchanges between the EU regions, cross-border cooperation – common programmes developed in the border regions and trans-national cooperation. The financial allocation for this objective is of 7,75 billion EUR, representing 2.52% of the cohesion policy funds and is totally financed by the ERDF.

For the financial period between 2007 and 2013, the policy frame will be closely related to the achievement of the objectives on the Lisbon Agenda and on the Goteborg Agenda.

Impact of Globalization on Business

Abstract

The 90s' represented the first decade through which worldwide national companies started to form a global vision. Still, the present is characterised by the tightening of the global competition. The more the companies fail to adopt the international view, the more increased is the risk of having them excluded from the emerging markets of Western and Eastern Europe, of Far –East Orient or of other world's regions.

Nowadays, the countries, forming the European common market, have abolished the barriers which blocked the free movement of goods, services, cash and people, by regulating certain activities, by the privatization of state-owned companies and by the adoption of common commercial practices. In the same time, new profitable opportunities have arisen in Eastern Europe, the countries from this region sustaining significant exertions in their transition from a planned-centralised economy to a market economy.

Key words: international business, multinational firms, export, foreign markets.

J.E.L. classification: F23, M16

1. Introduction

Although the interest of firms to access and compete in foreign markets is high, the risks are also high, this being due to external debt, unstable political regimes and governments, foreign exchange issues, government-imposed conditions on market access of foreign firms , bureaucracy, tariffs and other trade barriers, corruption, piracy technology and high production cost Although the interest of firms to access and compete in foreign markets is high, the risks

are also high, this being due to external debt, unstable political regimes and governments, foreign exchange issues, government-imposed conditions on market access of foreign firms , bureaucracy, tariffs and other trade barriers, corruption, piracy technology and high production cost.

A first conclusion that could have drawn from those presented is that whether they stay home or that are expanding abroad, companies are doomed. I infer from this that the only chance we have corporations doing business in the global industry is internationalizing operations they run.

When marketing gets extension activities in the international sphere, so when the country goes beyond the product was produced, and she receives the product policy of internationalization footprint, being necessary to adapt them to specific operating conditions in foreign markets.

Many of the fundamental principles of marketing management have been applied to the domestic market will be relevant in an international juncture. The process of identifying market opportunities, selecting strategies, implementation of selected strategies and performance monitoring involves similar principles to those applied domestically.

The main challenge for a company that wants to expand into other markets is to adapt marketing strategies that have worked on the domestic market to the needs of foreign markets, details of which can be completely different to what was known before.

2. The process of internationalization of business

To better understand the climate in which the multinational or transnational companies expand in the international environment is an analysis of the process of internationalization

of business, identifying its main influence of macro-and microeconomic factors. The postwar trend in international affairs have experienced three distinct periods:

Glorious period of thirty years (1945-1974), marked by economic recovery of the belligerent countries, backed by a strong commitment to foreign, mainly U.S., the global diffusion of consumer goods and soft drinks, cigarettes and automobiles. Most of these products come from multinational and transnational companies.

Oil shock period (1973/1974 – 1983/1984) the world's countries have realized the significance of economic uncertainty caused by soaring prices of raw materials, mainly those of oil, stimulating exports to offset bills ever higher required international suppliers of material resources.

Strategic searches Period (90's - 2000), which marks a redefinition of the economic relationships between states, with amplitude determined by global processes, such as those in Central and Eastern European transition to market economy and the deepening of integration within the Union European and its outer areas (such as North and Central America, South East Asia and the Pacific). Prospects for economic development triggered by the integration processes and redefining the conditions of action of various foreign markets in particular and the general world market for the end of the second millennium. [3]

World diminishes as speed increases communication, transport and termination of financial operations. Products made in any country are in great demand in other countries. In fact, many companies are operating internationally for decade's best. Today, however, global competition intensifies visible. Domestic firms that have not ever thought about the emergence of foreign competitors, they suddenly find themselves on their coast. Newspapers inform Japanese victories on the U.S. firms in areas such as production of household electronic goods, motorcycles, copy machines, cameras and watches, on massive imports of Japanese cars, German, Swedish and Korean market U.S., and of loss of markets for textiles and footwear imports from countries in the Third World. Even if some want to eliminate foreign competition through legislation, makes only lasting

protectionism has increased defense costs and inefficient domestic firms. To successfully cope with competition, the best would be for firms to improve their products in countries of origin and to expand business in foreign markets. [2]

3. Risks of multinational firms in foreign markets penetration

Although companies are forced to enter and operate in foreign markets, but the risks of this approach are high. There are many hazards, such as changing borders, unstable governments, currency, corruption and theft of technology. For this reason, it would conclude that all firms are doomed to destruction, whether they operate on their countries, whether they extend their business abroad.

A. High degree of external indebtedness. Many countries have accumulated huge foreign debt, having difficulty even paying interest only. These include Brazil, Poland and Mexico.

B. Unstable governments. In many countries, highly leveraged, high inflation and high unemployment rate have contributed to increased political instability, foreign firms seeing is threatened with expropriation, nationalization and limiting the repatriation of profits. To keep under control these risks, many companies resort fee, the political risk assessment reports.

C. Currency issues. The high degree of economic leverage and political instability lowers the value of a country's currency. Foreign firms that wish to make payments in hard currency, with the possibility of repatriation of profits, but there are many countries where these things can not be achieved.

D. Bureaucracy and market entry conditions imposed by the foreign state. Governments tend to subject foreign firms to a very strict regulatory regime. For example, regulations may require that the joint ventures, equity participation majority belong to the local partner, the firms that hire large numbers of locals and to transfer knowledge and technology, or may impose limits on profit repatriation.

E. Customs duties and other trade barriers. Often, states levy higher import duties, in order to protect their own sectors.

They also use a series of invisible trade barriers such as deliberately delaying the release of important permits the imposition of making costly changes to important products, verifying the performance of the slow passage through customs formalities for imported goods.

F. Corruption. To cooperate, officials in some countries have bribed, because award contracts to the tendered which has the highest bribe, not the one who came up with the lowest price.

G. Stealing technology. A firm has production capacity abroad is often problems because of their foreign managers learn how products are manufactured and then leave the company, making them compete openly or clandestinely. This happens in areas such as engineering industry, electronic industry, chemical and pharmaceutical industries.

H. The high cost of adapting products and marketing communication. A firm that is expanding abroad should carefully study each market to know better economic situation, laws, political and cultural environment of each country and to adapt products to consumer preferences Del. communications. Otherwise, it could be many and serious mistakes.

I. Changing borders. For the first time since 1945, many international borders tend to change. National boundaries are very important for marketing, because the forming and shaping their economic behavior. For marketers, the move could mean changing borders objectives.

However, the only option that is global companies from the sectors is to develop an international scale.

A global industry is an industry in which competitors' strategic positions on key national or geographic markets depend on their overall position in the global marketplace. [4]

A global company is a company operating in at least two countries and turn benefits from R & D, manufacturing, logistics, marketing and financial management, the cost advantages and reputation are not out of reach of its competitors in those countries

Global firms are planning, conduct and coordinate activities worldwide. To loosen and products on the world market, a firm need not be large. Small and medium enterprises can serve market niches, as do

many companies in Scandinavia and the Benelux countries.

Before taking a decision on expansion of operations abroad, the firm must weigh a number of risks: she could not know the preferences of foreign consumers and provide products uncompetitive, unattractive; it is possible that the company does not know the business culture of that country or do not know how to deal with local; it is possible to underestimate foreign regulations and have to bear unforeseen expenses; may find that the company lacks managers with international experience; it is possible to change the target country trade legislation, or to devalue the currency to have a revolution and to proceed with the expropriation of foreigners.

Because of conflicting risks and benefits, in many cases firms do not act on an international scale until something happens that does not inspire confidence in such an approach. Sometimes, the company exports its products to be requested by someone else: a domestic exporter, importer, or another foreign state. Other times, production capacity is surplus, and the company must find new markets for its products.

When deciding to go abroad, the company must define its policy objectives and international marketing. The question is: what will be the ratio between the volume of sales made abroad and the total volume of sales? When the companies adventures across the border, most businesses start with a small volume of sales. Some did not develop foreign market operations, considering them a small part of their overall activity. Others make plans broader view that foreign affairs will be reached eventually, at least as important as domestic markets activities.

The company must choose between entering the market or just a greater number of national markets. In general, it makes sense to operate in a smaller number of countries if the degree of involvement and penetration in each market is sufficiently large. A firm should enter a smaller number of markets where: cost control and market entry are high, costs of adaptation and communication products are great and the size and population and income growth are higher in countries initially chosen; dominant foreign firms may raise serious obstacles to market entry.

The firm also must determine the type of countries considered for expanding operations. The attractiveness of a country is determined by the size of the domestic product, geographic factors, income and population size, political climate and other factors. Exporter may have predilection for certain groups of countries or parts of the world. It is recommended that firms focus on exports to the "triad markets - the U.S., Western Europe and Japan - because they hold the largest share of international trade as a whole. [1]

If short-term profits are more likely to be higher in the three regions mentioned in the long run it can have disastrous effects for the world economy. Those markets are thriving, but mature: firms need to show more creativity to find any growth opportunities in the markets concerned. However, unmet needs of developing countries represent a huge opportunity for companies expanding. In those countries there is a huge demand for food, clothing, housing, household electronic devices, appliances and other goods. If the purchasing power of consumers in the third world will not be determined, in one way or another, to grow significantly, industrialized countries are still faced with excess production capacity and a slower pace of economic growth. In addition, developing economies will face an excessive consumer demand, which will not be able to satisfy. Many market leaders rush to reach markets in former communist Eastern Europe and the last bastions of communism, such as China and Vietnam, where there is a great need for technology and consumer goods of good quality.

In general, the candidate would initially be ranked according to three major criteria: market attractiveness, competitive advantage and risk. At first, specialists of the firm determine the market attractiveness of each country, based on indicators such as size's per capita GDP, the employment in the industry that serves the company, the volume of imports of such goods (such as those offered by the firm) and population growth. Then, they evaluate the competitive advantage that each of the countries surveyed it could provide the firm based on criteria such as past business ties, the ability to create those products with low cost and adaptability to company managers working style of those

countries. Finally, the experts assessed the risk level of each country, taking into account factors such as political stability, currency stability and profit repatriation regulations. Applying various indices, weighting and combining different values, draw a picture of the hierarchy of markets analyzed by the criteria above. Furthermore, specialists should conduct a financial analysis to see if the investment risk in each country concerned is justified to obtain sufficiently large gains.

4. Select how the market penetration of multinational firms

Having chosen a particular market, the company must determine how best to penetrate. Generic versions are: direct export indirect export licensing, creation of joint ventures and direct investment.

In order they are presented, each strategy involves an increasing degree of high involvement, risk control and profit potential.

Export processing occasionally requires a commitment from the company. This export activity from time to time, either on its own initiative or in response to spontaneous orders coming from abroad. *Exporting company actively* involved in expanding operations involve the sale of goods in a given market. In both cases, the company produces all goods in its country of origin, their adaptation to international markets is not compulsory. Exporting involves bringing in a minimum change product lines, organization, investment and business mission.

Export department or internal division. An export manager in charge of the actual sale of the commodity market and provide necessary assistance. Department can develop into a compartment by itself, making all export-related activities and operating as a profit center.

Foreign subsidiaries. It allows the manufacturer to be present on the domestic market and exert greater control of sales activity. Branch deals with the distribution and sale of goods, sometimes even with its storage and promotion. It also often serves as the hub of product presentation and customer service.

Representatives voyage export sales. Company can send abroad some sales agents to seek customers for its merchandise.

Foreign distributors or agents. To sell their products, the company can appeal to foreign distributors or agents, appointed on contract basis. It may give them an exclusive or limited right in that country. Whether one uses the strategy of indirect export to direct export or one of the best ways to initiate or expand export operations is the participation in an international trade show.

Licensing is a strategy that allows the manufacturer to easily penetrate foreign markets. It authorizes a foreign firm to use a manufacturing technique, a queen trade, patent, trade secret or other property of value in exchange for a fee or royalty. Thus, the licensor (the owner the right to license) with little risk penetrate foreign markets, and the licensee (the recipient the right to use) the choice of production experience with a product or known name, without having to take it from scratch. Coca Cola products on its worldwide bottling companies entering into contracts with, or rather license, franchise contracts. The company provides beneficiaries syrup concentrate and training services for the production, distribution and sale of products.

Licensing has, however, some possible disadvantages. Licensor exercised a lesser degree of control over the licensee unless and would have created their own production capacities. In addition, if the licensee is successful in his work, company profits do not benefit from it, and when the contract ends, it is possible to find the company that made them a competitor's hand. To avoid this, the licensor provides usually necessary to achieve certain product ingredients or components under exclusive patent (so carry Coca-Cola). But the best strategy is to dominate the licensor Chapter innovations, so that the licensee would always depend on him.

There are several licensing options. A company may enter into a management contract with the owners of a hotel, airport, hospital or other foreign organizations, administering it in exchange for a fee. In this case, the company no longer exports products, but services management. Contract management enables low risk entry in a foreign market, providing immediate gains.

This path is more attractive if the contracting company has an opportunity to buy some shares managed in a certain period. But there is no justification in any case, if the company can use its better management capabilities for other purposes or if they get higher profits by taking over the whole affair. The contract prevents the company management to compete with its customers.

Another method of entry is a contract manufacturing company that appeals to local producers in order to achieve its products. This method has a drawback, however: the firm exercise less control over the production process and the potential production losses. However, it gives the company the opportunity to start work quickly, with less risk and with the option to form a partnership or to buy the company after listing.

Finally, a firm may enter a foreign market by entering into a franchise agreement, which is actually a more complete form of licensing. In this case, the seller provides the beneficiary with a complete system, consisting of brand name and operating technique. Instead, the beneficiary is obliged to make investments and pay certain fees transferor. Companies like McDonald's and KFC widely used this method for penetrating foreign markets.

The Marketing vs. R&D Dilemma in the Romanian Soft Drinks Industry and Implications on Consumer Health

Chiru Codrin

The Academy of Economic Studies, Bucharest

icchiru@yahoo.com

Abstract

The management literature and practice have flagged many times the barriers between research and development (R&D) and marketing activities. Although representing "different cultures", it is believed that if both functions collaborate well, then both technological and marketing powers would increase exponentially. Most of the Romanian soft drinks companies have a limited understanding of the new approach of integrating them, based on the strategic marketing as the key component, essential for the product development phase.

This study presents several cases of how soft drinks bottlers use alimentary additives which, if consumed in high quantities, could represent a threat to consumer health and also how some marketing disruptive techniques could artificially maximize the new products value and also hinder consumers understanding, knowledge and freedom of choice. Finally this paper proves that the relation between R&D and marketing in the food & drinks industry could be key to assuring the right balance between scientific research and value communication in order to improve consumers' health on the long term.

Key words: Food safety, Marketing, Additives, R&D, Consumer health

J.E.L classification: M21, M31, I10.

1. The landscape of the Romanian soft drinks market

Romanian soft drinks market takes the largest share of all commercial beverages, and continue to drive growth, being estimated at nearly 3,2 billion liters and 2,8 billion euros. In 2010 the top bottling companies were Coca-Cola, Romaqua, Pepsi and European Drinks, owning together more

than two thirds of the soft drinks market. [1] The competition is increasingly higher, as like as the marketing budgets, Coca Cola being the most important advertiser, having a yearly promotional budget of over 100 million euros.

During the last five years the Romanian consumers have been increasingly turning towards healthier consumption, helped by stronger purchasing power. [1] Consumers evolved from indulgency, pleasure seekers to dynamism, energy driven people and recently health and personal image builders. Therefore the market turned from carbonated drinks into still drinks and more recently to more sophisticated soft drinks like juices, ice-teas and energy drinks. The fastest growing categories in the last years were: ice tea, energy drinks, still drinks and packaged water. Producers adapted accordingly and today the marketing focus is on healthy, natural and dietetic products. But the producers need to balance the increasingly high consumers demands with the costs occurred. Consumers want fresh, tasty, healthy products at good shelf price and convenience. The result of the increasing consumer demands like brighter, sweeter, long lasting is the actual presence of over 1000 different additives that are widely introduced into non-alcoholic beverages to produce a desired effect, which is a largely accepted practice but not without controversy.

2. Collaboration issues between Marketing and R&D teams

A short and comprehensive expression of the marketing tasks would be that marketers are skilled in stimulating demand for their products. [2] But the demand management is just a small part of the activity of a marketing department. A broader view is that marketing department should lead the entire marketing

process in a company focused on value creation. This new approach is based on so called "value delivery sequence" which was improved by adding the strategic marketing component. This component includes value positioning process, which is essential for the following phase: product development. At this phase the collaboration between Marketing and R&D departments become crucial. Steps like: new product strategy, idea generation and screening, concept development and testing, product development, test marketing and commercialization [3] must be undertaken jointly by both departments.

To reveal the latest developments and trends regarding the actual marketing and R&D collaboration issues in Romania, a qualitative research was developed and implemented by the author. The research method was the extensive interview; the target group was the managerial staff selected from the top 10 Romanian soft drinks producers; each interview consisted in 15 closed questions, with complete system of choice and 5 additional specific questions, using a nonparametric type ordinal scale.

The study revealed that in Romania it is a common thinking that product strategy, marketing research and test and also commercialization are the exclusive tasks of the marketing department. Romanian researchers are very used to execute and have very limited implications in the products marketization. This lack of integration and knowledge exchange between these two functions create several shortcomings for the Romanian marketers. The most relevant are:

- A limited understanding of the chemical and biological phenomena and processes that happen during various stages like flavours manufacturing, additives preparation, bottling;
- A limited economical assessment of the use of alimentary additives;
- An underestimation of the long term impact of additives on consumer health.

The generally mission of the R&D department is to design safe and attractive products according to their company strategy. As a primary source for new technologies and knowledge, R&D department members have to manage the market trends, customer evolution, in the end the social function of technology.[4]

Overall, the majority of companies have a mix of internal and external technology sources. The sources from outside are most often:

- equipment suppliers (bottling lines);
- raw material suppliers (mainly concentrates and additives).

The most innovative companies like world giants Coca Cola or Pepsi possess their own concentrates based on proprietary recipes (e.g. Coca-Cola "secret formula"). But most of the Romanian soft drinks producers use external recipes for their drinks supplied by large fruit concentrate producers (e.g. Döhler Group). Therefore the main tasks of their R&D personnel are to adapt the recipes (if case) and to monitor the production process. The development of new recipes is less operational since the Romanian market is less developed than other EU markets in terms of consumption per capita and trends. Also new trends like ice tea, smoothies, flavoured water or aqua plus have been visible in Romania only long time after they were launched in United States and Western Europe.

This research revealed also that many Romanian soft drink bottlers have a very limited technological infrastructure, sometimes just an average laboratory which has to monitor the products quality and safety. These laboratories are placed near or in the production facilities, many times at a long distance from the company headquarter. They are usually under the direct supervision and hierarchical subordination of the production managers. Generally, these managers have as main responsibilities the overall management of the ongoing production operations including: inventory control, scheduling, documentation, equipment maintenance, calibration, shipping, and quality tracking and control. The production managers report directly to general managers or to the COOs (Chief Operating Officer), by case. Therefore the relations between Marketing and R&D teams can only be cross-departmental. Moreover, being assigned to the production function, the R&D activity becomes more operational, focused on daily monitoring and supervision of the technical processes rather than dedicated to innovation and new product development. The lack of communication and different priorities are the main obstacles

in the collaboration process between marketing and R&D in many companies from the Romanian soft drinks sector. This situation triggered a non innovative character of the Romanian soft drinks market, most of the leading products and marketing concepts being adaptations or replicas of the commercial hits from other EU countries or United States. Moreover, some sensitive and elaborated technical details regarding the flavours production and soft drinks bottling processes are known only by a very small number of employees (top managers) due to the recipes protection policies of the companies.

The research conclusions regarding the main shortcomings of the R&D staff are:

- R&D employees have a lack of vision and strategic approach, therefore many research activities could not be economical justified;

- There R&D experts underestimate their social and ethical role being unaware about their key position in the entire marketing process, including the responsibility of using healthy ingredients.

- Furthermore the lack of integration between R&D and marketing could affect company overall competitiveness and technological autonomy. If a soft drinks producer lost its R&D and marketing capabilities then it would become just a bottling facility.

3. The market regulations – are they effective?

The EU legal framework for usage and traceability of food additives is given by Regulation (EC) 1333/2008 of the European Parliament and the Council on Food Additives. Food additives must be safe when used, there must be a technological need for their use, and their use must not mislead the consumer and must be of benefit to the consumer. The advantages and benefits for consumers are managed in two ways:

- The agreement among The European Commission and the Member States Governments;

- The Commission may ask EFSA for scientific advice in relation to benefits.

Moreover, European Parliament and Council Directives 94/35/EC, 94/36/EC and 95/2/EC require each Member State to

monitor the consumption and usage of food additives. The European Commission is required to submit a report on this monitoring exercise to the European Parliament and Council.

Romania has adopted a series of laws in order to comply with the EU *acquis*. Labeling and food additives legislation were enacted before 2007 [5], [6], [7] and updated several times according to EC directives. Romanian Ministry of Health, through its Regional Public Health bodies has the responsibility to evaluate, supervise, implement and monitor the food additives policies in Romania [6]. These assumed responsibilities should include food market monitoring and food poisoning prevention. In order to track the additive usage the Ministry of Health should have adequate equipment for food content chemical analysis, very effective investigation system at national or at regional level and more important highly qualified experts in scientific risk assessment. Furthermore, the Ministry of Health should cooperate with other market control bodies, like the National Authority for Consumers Protection to better cover the territory and also share good investigation practices. So far there were only isolated initiatives to assess the risk of food additives in Romania and seems like the capacity to determine whether producers comply with the legislation in force is very limited in this case.

4. Consumers are caught in the middle

When making a purchasing decision, consumers use the information provided by producers, retailers, mass media, consumer organizations, etc. This information reaches consumers minds through various channels and in various ways. Promotional activities are more and more effective in changing the consumers' attitudes and purchasing preferences. Here will be presented two approaches used by soft drinks producers to artificially maximize their products value: *umbrella branding* and *disruptive labeling*.

The concept of *umbrella branding* consists in applying the name of a brand to a broad range of consumer goods. The goal is to spread positive elements of a brand's value over other products using transfer processes like semantic generalization. [8] This

marketing technique can bring more beverages subcategories under the same brand, like juices (100% fruit content), nectars (50 % fruit content) and still drink (4% fruit content). Therefore when the producer heavily promotes the juice line, emphasizing its natural and healthy character, promoting fruit benefits (tasty, healthy, etc.) the less qualitative subcategories (i.e. still drinks), marketed under the same name, take advantage and capitalize the superior image of the better product. [20] Still drinks, although being much cheaper but having the same name and some key visuals similar or very close to those of the juice products, are often perceived by consumers like natural, healthy soft drinks. The presence of the fruits on the label strengthens the perception that they are a beverage made from fresh fruits. In reality they are very often just artificial made products with a very low concentration of fruit juice (4%) and many additives. A broadly known example of umbrella branding is Cappy, owned by The Coca-Cola Co. In Romania are marketed the following variants:

a) *Cappy Premium* is a 100% juice, advertised as a healthy, natural product, obtained from squeezed fruits with no artificial colorants or preservatives; the aseptic packaging ensures shelf stability without the use of preservatives and/or refrigeration (juice definition: 100% pure fruit juice or vegetable juice with no added ingredients, except permitted minerals and vitamins) [1].

b) *Cappy Tempo* is a 4% juice based still drink, advertised as a tasty drink based on fruit juice at a convenient price; (still drink definition [1]: flavoured ready-to-drink, non-carbonated products, which may be fruit or non-fruit flavoured and have a juice content of 0-25%. Sugar, artificial flavouring and colouring may be added. Excludes non-carbonated tea-based products where juice content is less than 5% (included in iced/rtd tea drinks) and any still products making specific sports or energy performance-enhancing claims (included in sports drinks and energy drinks respectively);

c) *Cappy Tempo Light* is also a 4% fruit juice still drink, positioned as a diet soft drink (it has no sugar).

Table 1 Cappy soft drink variants and key chemical ingredients

	Cappy Premium Orange	Cappy Tempo Light Orange
Package	Carton, 1L	PET, 2L
Ingredients specified on the product label:	100% orange juice, pasteurized, no preservatives	4% orange juice E 211 (sodium benzoate) E 952 (sodium cyclamate) E 950 (acesulfame K) E951 (aspartame)
Shelf Price/item	5, 49 RON (1,3 EUR)	3,79 RON (0,9 EUR)
Shelf Price/liter	5,49 RON (1,3 EUR)	1,89 RON (0,45 EUR)

Source: Author made price survey.

Note: Price is only referential and was collected from five stores; it may differ from the average market price.

Both products are marketed under the same name, same logo and many similar visual identity elements. The *halo effect* is evident: some consumers may think that both above presented products are the same, but in different types of packages. Some more may think that Cappy Tempo is a natural drink, not as good as Cappy Premium, but still a healthy, natural product at a very good price. It is known that only few consumers will carefully read the label and will find out that Cappy Tempo (including his "Light" variant) is totally different than the Premium version, being a mainstream still drink with only 4% fruit juice and many additives: E 211 (sodium benzoate), E 952 (sodium cyclamate), E 950 (acesulfame K), E951 (aspartame)

5. Disruptive labeling – a common practice

The main identified labeling issues are

1. The fruits emphasis on labels: almost all soft drinks claim a strong fruit presence by their fancy and colored packages on which various fruits are represented, although some of them contain not only a very small quantity of natural fruit juice (4%), but also various controversial additives. Romanian legislation allows the usage of fruit pictures / illustrations on product's label, package and

promotional materials if the respective fruit juice is among product's ingredients. No minimum level of juice is specified so far. Moreover, if the concentration of the fruit juice is at least 4%, the bottler must use the wording "orange juice" or lemon juice"[6].

2. The label content: the additives are often if not omitted then incompletely described. Romanian producers know about the increasingly awareness of Romanian public about the additives health issues and in several cases they use some legislation interpretations. The labeling regulations consider some substances as not being "ingredients" (e.g. technological auxiliary additives). Romanian legislation stipulates in HG 106/2002, which regulates labeling of the alimentary products, that only "ingredients" are to be mentioned on the aliment's label. Such a case is the additive E242, Dimethyl dicarbonate (also known as DMDC or Velcorine) which is used as a a microbial control agent in beverages including juices, flavored water beverages (carbonated and non-carbonated), still drinks and ice teas that contain low levels of juice or artificial or natural flavors. Once it has been added to beverages, it has the following chemical reaction:

Although it forms methanol, a known carcinogen and toxic compound [16], EU and US official scientific and regulatory bodies consider it safe for human consumption at a maximum level of 250mg/liter.

The usage of the technical or scientific additive's name (e.g. instead of E211, it is used "sodium benzoate"). Consumers are aware more about "E" substances and less about their technical names.

3. The labels do not mention the quantities of additives used in a product. Even though producers use the quantities approved by law, people usually consume a mix of alimentary products during a day. Therefore the quantum of the total daily intake of an additive is not possible to be known by a Romanian consumer. This is the case of the majority of the artificial sweeteners, colorants and preservatives used in the soft drinks industry. The lack of information about quantities of additives used in a product put the consumers' health at risk. Even if the Romanian consumers knew the

values of various ADIs they would not be able to determine how much to eat or drink from each type of alimentary product in order to avoid additives overdoses.

6. Conclusions and recommendations

1. There is an acute need to increase the synergy between marketing and R&D in both private and public sectors, to raise awareness of marketing and research teams who work in the beverages industry about their joint responsibility for the public health;

2. The Romanian and EU legislation should be further updated and improved by:

2.1. Aligning the maximum levels of additives allowed in Romania to the ADI levels adopted by other EU members that have higher scientific assessment capabilities of their effects on health (e.g. UK, Germany, Denmark, France);

2.2. Improving the Romanian labeling regulations by rising the minimum concentration of juice for the products traded under the name "with fruit juice"; also prohibit the use of fruit representations on the packages and promotional materials of soft drinks that have a juice content less than 25%;

2.3. Introducing the obligation for the soft drinks bottlers to mention on the package the quantities of each alimentary additive that exists in the composition of a product, using the nutrition labels model;

2.4. Preventing the disruptive effect of the *umbrella branding* techniques (*halo effect*) by adopting new audio-visual regulations in order to avoid misinterpretation of the promotional messages and confusions (e.g. the exposed case of natural juices and still drinks)

3. Romanian authorities need to strengthen the tracing and monitoring capabilities of the Ministry of Health to identify more efficiently the non conforming products present on the market, to prevent the infringement of the additive maximum admitted levels and assure the good implementation of the food safety policies;

4. The Romanian society need to have stronger non-governmental consumer protection organizations, able to assist The Ministry of Health to better monitor and control the additives presence in food and drinks;

5. All the responsible stakeholders should increase consumer awareness about the possible long terms effects of the alimentary additives and guide the children to consume healthier beverages (e.g. mineral water, fresh made juices, smoothies, etc.).

Assets and Liabilities Management – Concept and Optimal Organization

Ciobotea Adina
Oacă Sorina Cristina
Academy of Economic Studies, Bucharest
adina.ciobotea@gmail.com
oacasorina@yahoo.com

Abstract

Asset-liability management (ALM) is a term whose meaning has evolved. It is used in slightly different ways in different contexts. ALM was pioneered by financial institutions, but corporations now also apply ALM techniques.

In banking, asset and liability management is the practice of managing risks that arise due to mismatches between the assets and liabilities (debts and assets) of the bank. This can also be seen in insurance. Banks face several risks such as the liquidity risk, interest rate risk, credit risk and operational risk. Asset Liability management (ALM) is a strategic management tool to manage interest rate risk and liquidity risk faced by banks, other financial services companies and corporations.

ALM is defined as "the process of decision making to control risks of existence, stability and growth of a system through the dynamic balances of its assets and liabilities."

Key words: assets and liabilities management, banks, insurance companies

J.E.L. classification: D53; G1; G21; G22, G23, G24, G32

1. Introduction

The Asset and Liability Management Department is a creation that evolved out of banking and insurance history. The financial crisis of the 80s and 90s proved the importance of Risk Management in decision taking. During this period, frightened executive managers created or empowered Risk Management Departments. In the same period ALM teams were formed, bringing organisation and strategy into question.

At the beginning of the 90s, ALM teams in banks were usually integrated in Finance Departments or Risk Management Departments. In insurance Companies, ALM teams were considered initially to be insurance risk management teams.

Nowadays, ALM teams tend to be independent from Finance and Risk management teams.

In banks, the organization makes a distinction between risk management (RM), treasury and financial direction. The ALM position in the bank organization is often inside the Risk Management, sometimes inside the Treasury Department and sometimes inside the Budget Department.

Risk management looks after the risks and historically after the credit risk and the market risk included in trading books.

The treasury objective is often to monitor very short term liquidity risk and to reduce

bid/ask on interbank loans and the cost of deposits. The treasury has access to financial markets with the objective of a better volume/cost arbitrage. The treasury pilots the overall liquidity position.

Financial direction looks after accounting and budgeting.

The position of ALM in the organisation depends on the orientation decided upon by the bank's executive management: either more risk oriented, or more investment oriented.

In primitive organizations, ALM is a part of Risk Management and the treasury has the responsibility of investment.

In advanced organizations, ALM acts as a long term treasury responsible for long-term investments and for associated risks. In such a case, there is a need for an independent team to monitor the accuracy between reports and the position in reality.

In **insurance organizations**, ALM usually plays the risk management role. The Investment department plays the role of the Treasury Department.

In Investment funds, the role of ALM is divided between the fund managers (for investment), the financial directors (for strategy and marketing) and sometimes the risk management team.

In market equilibrium, ALM seeks to find the points of equilibrium between risk aversion (with preference for the present, for the fixed rate borrowing, etc) and the risk premium earned when taking positions.

ALM represents the banker, the insurer or the asset manager role in order to take a calculated risk for a premium in front of a market that is risk averse.

This is called „Transformation“:

- when lending using long fixed rates loans and accepting short floating rate deposits;
- when lending using long-term loans and accepting sight deposits
- when playing with long/short Equity
- when replacing long short-term insurance contracts

ALM role is assuming importance at a time of banking system concentration.

2. The objectives of ALM

ALM teams now have a set of responsibilities. The ALCO (the ALM Committee) is in charge of:

- short-term and long-term treasury activities (liquidity risk management)
- other ALM risks management: interest rate risk, optional risks, exchange rate risk, etc
- Funds Transfer Pricing modelling and ALM income computation
- conformity with local regulations and statutory obligations
- optimization of risks return and capital management

2.1. Liquidity Management

Liquidity Management is the first ALM objective:

- providing cash for all the business lines of the company, giving them full access to liquidity for every kind of liquidity need for each maturity in every country
- optimizing the short and long term funding costs, making the executive management secure about liquidity risk exposure
- optimizing the cost with a given rating target
- preparing liquidity contingency plans and being prepared for liquidity crisis

- monitoring liquidity (volume, cost, liquidity sources, etc)
- computing liquidity risk indicators (internal and regulatory indicators)
- providing to executive management centralized liquidity management and monitoring

2.2. Funds Transfer Pricing (FTP) and modelling

ALM teams are responsible for FTP implementation and control. The process has to be validated with the executive management and by the business lines. Executive management guarantees an identical approach for all the business lines. To implement FTPs the A/L manager will need precise financial information about the balance sheet products.

2.3. Capital and income management

a) ALM risk position

The definitions of the risk taking strategies is an essential part of the A/L manager's task. ALM should contribute to the profitability of the company:

- developing a contracyclic management to protect business lines against the cyclicity of the economy
- taking adequate risk positions

The business lines margins are protected against behavioural risks. ALM recuperates the financial risks and the volatility on the income due to those financial risks.

ALM will insure a centralized analysis and a centralized management of the financial risks. Income optimization is managed by ALM. This optimization requires a delegation of decisions.

b) ALM and budget

In the company's budget programme, ALM is essential for income prediction.

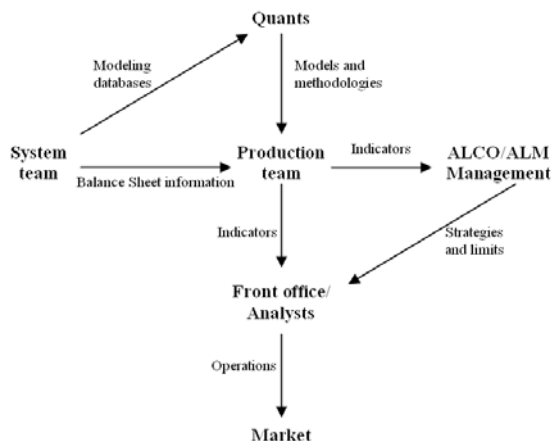

Nevertheless, ALM teams will not have also to concentrate on a 2-3 year budget horizon.

The risk supported by ALM teams is longer than could be expected.

Economic value management will take into account the long-term ALM investments in the budget environment.

The budget plan for business lines has to be in line with the ALM budget plan.

Figure 1. ALM Organization

3. ALCO: the ALM Committee

A risk-management committee in a bank or other lending institution that generally comprises the senior-management levels of the institution. The ALCO's primary goal is to evaluate, monitor and approve practices relating to risk due to imbalances in the capital structure.

For example, the ALCO will have responsibility for setting limits on the arbitrage of borrowing in the short-term markets, while lending long-term instruments. Among the factors considered are liquidity risk, interest rate risk, operational risk and external events that may affect the bank's forecast and strategic balance-sheet allocations. The ALCO will generally report to the board of directors and will also have regulatory reporting responsibilities.

The ALM committee or ALCO is often the heart of the ALM organization.

There are different ALCOs, as in large companies many ALCOs exist:

- a central ALCO, which centralizes all the ALM information at the company level. All the other ALCOs report to the central ALCO and the head of Central ALM is present at all these other ALCOs.
- business lines ALCOs where the business lines specific ALM problems are studied in detail
- local ALCOs where the ALM problems of a specific country are studied in details (problems due to a different regulatory environment, to local treasury difficulties, etc)

ALCO Members

The ALM committee usually consists of:

- a member of the executive management of the company, sometimes the CEO (the Chief Executive Officer, who usually presides the ALCO as a chairman)
- the head of the ALM Department and the executive ALM members
- the head of Treasury Department
- the Chief Operating Officer
- the head of the Finance Department
- the heads of the major business lines (consumer banking, corporate banking etc) and the head of Marketing Department
- the head of the Risk Department and the Compliance director

The presence of the head of the Risk Management Department is necessary in order to establish a potential source of opposition. This opposition is necessary in order to validate the rules and the strategies proposed during the ALCO.

3.1. Frequency and rules

The ALCOs administrative rules should be known by everyone and be reviewed regularly. The ALCO takes place at least in a monthly basis or on a weekly basis depending on the situation of the company and on the need for intra monthly strategy management.

ALCO crisis committees can convene as soon as the executive management or the head of ALM requires it.

Reporting to the executive management and to the board should be done at least on an annual basis.

3.2. ALCOs role and agenda

The board of directors is naturally responsible for:

- financial risk management (including global interest rate risk, liquidity risk, exchange rate risk, etc, but excluding market risk) with delegation to the ALCO.
- credit risk management with delegation to the credit risk committee
- market risk management with delegation to the market risk committee

Audit teams and risk teams are usually responsible for consolidated risk reporting:

- economic risk
- credit risk
- market risk

- operational risk

ALCO will focus mainly on the financial risk management and in particular ALCO will look after procedures and after risk management policies. Also ALCO will verify that the ALM human resources are sufficient to perform all the ALM tasks.

Moreover, ALCO is the occasion to discuss business activity and its link with ALM topics.

The usual ALCO agenda is as following:

- presentation of the previous ALCO minutes
- commercial activity and development
- risk measurement, FTP rules validation and risk limit policy
- risk and income management and customer products pricing

a) The presentation of ALCO minutes

At the end of an ALCO, key points and action points should be highlighted in the ALCO minutes. These minutes should be sent promptly to the ALCO participants.

At the beginning of the next ALCO, the minutes are reread. The action points made in the last ALCO meeting should be reviewed in order to ensure their implementation.

b) Commercial activity and development

The marketing Department is responsible for product innovation and the pricing of existing products.

The head of this department is invited at ALCO to present activity and commercial development and in particular:

- the evolution of new contract production per customer type
- evolution of prepayments
- evolution of customer optional behaviours (closing rates etc)
- marketing campaigns
- overview of customer prices and competitor's prices

Moreover, the balance sheet should be presented. For instance in a bank, those figures should be presented as follows:

- for the loans: the average amounts, the figures, the average life, the average margin, the average rate, the average FTP and the proportion of fixed rate loans by year of production
- also for the loans: a reporting of the implicit/explicit options (repayments, prepayments, etc), the loan monthly new production and the fixed rate liquidity schedules;
- the same for deposits by year of production and by deposit type

- a reporting for all the funding instruments and for the possible future funding deals
- a reporting of the other elements of the balance sheet evolution, equity capital, provisions, bonds etc

Finally, the whole balance sheet should be presented at the ALCO: in terms of outstanding amounts and flows (past flows and future flows expected flows through marketing campaigns presentation).

3.3. Risk measurement, FTP rule validation and risk limit policy

After the presentation of the balance sheet in a historical and in a prospective way, it is time to present the balance sheet risks.

For every indicator, the A/L managers will present the hypotheses behind this computation. Moreover, the A/L manager will present the indicator variation and explain it through the computation of the indicator sensitivity.

3.3.1. FTP rules validation

Regular specific studies will help the ALCO to achieve FTP rule implementation and review. The proposed FTP rules modifications are presented during the ALCO (the ALCO is in charge of their validation).

3.3.2. Liquidity risk indicators

The ALCO will look after the classic liquidity indicators, the regulatory ones and the internal ones. The following indicators will be presented:

- liquidity gap: static and dynamic gap
- current funding composition and provisional evolution
- historical funding costs and prediction of the funding costs
- future liquidity needs
- credit lines reporting
- funding sources
- rating perspective
- loan to deposit ratio and other regulatory ratios
- liquidity contingency plan

3.4. Specificity of the Insurance ALCO

As an example, we present some points that should be highlighted during an insurance ALCO:

1. The flows should be presented in a adequate table:

- flows on the liability side by product (new contract in numbers and amounts by duration)
 - contract closing rates as a function of the contract seniority
 - marketing campaigns
 - flows on the asset side (realized hedging strategies: bonds, indexed bonds, equity and real estate)
 - derivative reporting
2. Benchmarking should be developed through competitor's campaigns presentation.

The committee should spend time on the presentation of the indicators, income sensitivity simulations (including stress scenarios) and hedging strategies definition.

4. Conclusion

Banks and other financial institutions are in the business of taking on risk, using their expertise in risk valuation to generate return. In many cases this activity involves using some very sophisticated instruments. The types of risk exposure taken on can be subtle and complex, reflecting not only the individual products themselves, but also interacting with external market factors.

Therefore when assessing risk exposure it is important to consider the bank's balance sheet at whole. The bank's ALM committee (ALCO) will take just this approach, managing the bank's asset and liabilities and being responsible for overseeing liquidity and market risk at the highest level.

Given the importance of banks in the world's economy, this responsibility is not a minor one. Liquidity, the ability of a bank to generate cash at short notice and low cost, is key to the smooth running of the financial system. Ineffective liquidity planning can have an impact far beyond the individual bank level. Similarly, market risk exposure, including yield curve risk and gap risk, requires careful management and reporting.

In managing these risks, no single measurement or ratio gives the complete picture. To assess liquidity risk we need to consider the entire balance sheet. Assessing and managing market risk is also a complex activity. The two risks frequently overlap, and the ALM discipline recognizes this by overseeing both risks concurrently. It is more of an art than a science, as the ALCO has to assess future market scenarios and their probability of occurring, and plan for each of these accordingly. As well as positioning for the bank to be in strong shape under any

eventuality, the ALCO will also need to allocate assets and liabilities in order to meet profit and return on equity (ROE) targets.

The tools and techniques available to the ALM practitioners are many and varied.

Investment Decisions in the Romanian Pension Funds

Ciobotea Adina
Oacă Sorina Cristina
Academy of Economic Studies, Bucharest
adina.ciobotea@gmail.com
oacisorina@yahoo.com

Abstract

The paper presents the needs of a reliable pension fund system as a consequence of the ageing of the population. The sustainability of the privately administrated pension funds is given by the administrators' investment decision. The pension fund participants would aim for a low contribution and expect for a prospective high return. At this point is the administrator's decision to invest the fund in a high return – high risk portfolio that would lead to a high volatility or in a moderate return portfolio with a manageable risk.

Key words: pension funds, decision theory, asset and liabilities management

J.E.L. classification: G23; G17; G11;

1. Introduction

The fact that the life expectancy is increasing year by year with the help of developments in medicine and improvements in lifestyle is well known and appreciated. But along with this individuals and governments have to find solutions for the longer retirement.

The British organization "Help the Aged" said that "today almost 1 in 10 people globally are over 60. By 2025 the figure will be 1 in 5."

According to the 2010 data published by the World Health Organization in 2008 the life expectancy at birth in Romania was 69,6 years for males and 77.1 years for females. While the life expectancy at the retirement age was 13,9 years for a male at the age of 65 and 21 years for a female at the age of 60.

For the European region the life expectancy at birth in 2008 was 70,9 for males and 78,6 for females while the life

expectancy for 65 years old male was 15,4 years and for a 60 years old female was 22,8 years.

The trend of the life expectancy is obviously increasing if we look at the historical data. Moreover it is forecasted that in 2030 in the European Union the life expectancy for females will increase to 85,3 years and for males will go up to 80 years. As expected, for Romania the forecast shows lower levels of life expectancy 82,2 years for women and 75,5 years for men.

Table 1

2008		
	life expectancy	
age	male	female
0	69,6	77,1
60	17,1	21
65	13,9	17
2000		
	life expectancy	
age	male	female
0	67,7	74,7
60	16,4	19,8
65	13,4	15,9
1990		
	life expectancy	
age	male	female
0	66,8	73,3
60	16,4	19,1
65	13,2	15,2

Source: the statistics database of the World Health Organization [4]

The forecast for 2030 is based on current situation of growth in the medicine innovation and health developments. But the limit of medicine and its impact on life expectancies cannot be quantified.

The unanticipated reduction in mortality rates was named longevity risk. The longevity risk impacts significantly the government, the individuals, the employers and the insurance/ pension industry. As a consequence "Insurers, governments and pension providers must act now to ensure that living longer remains a benefit to society, rather than a financial burden." said Christian Mumenthaler, Head of Life & Health Products, Swiss Re.[5]

2. Pension Benefits Alternatives

Solutions exist to offer protection at retirement and to overcome the longevity risk but influence the individuals and the pension companies in different ways.

There are two different pension plans offered by the pension/insurance industry. One is the defined benefit pension plan and the other one is the defined contribution pension plan. Defined-benefit plans promise to pay employees an income when they retire, typically at a level based on their length of service and salary, for the rest of their lives.

The defined contribution pension plans is a retirement plan in which a certain amount or percentage of money is set aside each year by a company or the individual for the benefit of the employee. It is clear from the beginning that in the case of defined benefit pension plans the risk is mainly held by the employer that provide the benefit or the insurance that offer the product while in the case of the defined contribution pension plans the risk is passed to the individual to estimate her/his needs for retirement income.

In Romania, at the moment, only the defined contribution pension plans exist. This might be explained through the fact that the life expectancy of the Romanian population is expected to have a steeper increase than the other more developed countries that encountered this phenomenon some decades ago.

Besides having well established private pension systems the more developed countries can benefit also from developed capital markets and more sophisticated financial instruments like the longevity swaps. "In longevity swaps, the insurance company gives investors a stream of payments. The investors, in return, commit to paying the insurer if the beneficiaries of the pensions or annuities covered by the swap live longer, on average, than originally

anticipated, thus making the income that they receive more than expected." (Mark Kolakowski, About.com Guide).

3. Short description of the Romanian Pension System

In the context of the ageing population a pension system to allow for the future increases in retired population was needed. As a result three Pension Pillars were created in the Romanian pension system. The Pillar I represents the pension provided by the governmental budget, these is a pay-as-you-go type of pension and was the only existing before the reform.

The Pillar II is a defined contribution scheme with private administration. This scheme is mandatory for persons less than 35 years old, optional until a maximum age of 45 years. The Pillar II participants have a contribution of 2% out of the monthly salary. This percent is expected to be increased gradually to reach 6% in the following years. In addition the Pillar II differs through the fact that the contributions are made in individual accounts which can be inherited if the owner dies before retirement.

Moreover Pillar III stands for optional privately administrated funds; these are defined benefits type of pensions.

At start there were 18 private funds operating for the over 4 million possible participants. But four of them had a portfolio of less than 2000 clients and decided to exit the pension industry. Their portfolios of clients were equally divided through the remaining 14 players that were in the market at the time. In February 2011 the CSSPP had on the list 9 pension administrators for the mandatory private pension contributions. The number of pension funds shrank from 2007 as a consequence of mergers and acquisitions in the market.

At the end of February 2011 the number of participants included in the private mandatory pension system were 5,2 million while the total asset under management in the market was 4.682 million RON.

The total asset under management increases on one hand as a consequence on the increasing number of participants and on the other hand as a result of the increase in contribution percentage. In 2011 the contribution the mandatory privately administrated pension was set to 3% of the gross salary.

The amount of asset under management is high and moreover the degree of reliability of the funds needs to be high since the benefits will start to be paid even 40 years from now and for an uncertain period of time due to the increasing life expectancy.

4. The Investment Decision

The pension funds represent long term investment as a result specific investment decisions are taken in order to maintain the sustainability of the fund.

The Assets and Liabilities Management starts to become more in focus for the pension funds as a consequence of the regulations, ageing of the population and increasing competition.[3]

The participant to a pension fund would aim for as high as possible return for her/his investment. This means that with a minimum contribution the pension fund administrator should obtain an expected pension payment.

The participant contributes to a fund that is accumulated and invested in diverse instruments like governmental bonds, corporate bonds and equities. The investment instruments have different degrees of risk and consequently different returns. The highest return would be provided by the risky investments which also lead to volatility in returns. The volatility of the investment portfolio is not positively seen by neither the administrator of the pension fund and the regulator of the pension fund market. The Romanian pension fund market regulator is CSSPP (Comisia de Supraveghere a Sistemului de Pensii Private). "The mission of this state supervisory body is: to protect the interests of those affiliated to the Pension System, by assuring an efficient functioning of this system and to authorize and supervise the activities carried out in the Pension System." (<http://www.csspp.ro/misiune>). [6]

To better inform the participant the regulator imposed that the pension funds that operates in Romania should describe their risk appetite and adhere to one of the three risk positions: low risk, medium risk and high risk. At the moment (March 2011) are 9 administrators of mandatory pensions in Romania, 8 are medium risk and 1 was positioned as high risk. There is no low risk fund. The one fund that was positioned in the high risk class had one of the top performances in terms of returns but not the

best one as expected from the risky investments. This shows a sometimes inefficient assets and liabilities management.(see Fig.1)

Fig.1. The returns of the mandatory pension funds in February 2011

Risk level	Private Pension Fund Pillar 2	Return February 2011
Medium	Fondul de Pensii Administrat Privat VITAL	11.1365%
	Fondul de Pensii Administrat Privat AZT VIITORUL TĂU	15.1155%
	Fondul de Pensii Administrat Privat BRD	12.4965%
	Fondul de Pensii Administrat Privat BCR	14.1767%
	Fondul de Pensii Administrat Privat ING	15.5138%
	Fondul de Pensii Administrat Privat EUREKO	13.8491%
	Fondul de Pensii Administrat Privat ALICO	14.4503%

Source: <http://www.csspp.ro/rate-de-rentabilitate/pilonul-2>

Data published by the Romanian Private Pension System Supervisory Commission (CSSPP) [6]

In the voluntary pension funds market (Pillar3) are 10 players, 2 in the low risk sector, 6 positioned as medium risk and 2 in the high risk category. Also contrary to the expectations, in this market some of the medium risk funds performed better in terms of return than some of the high risk funds and the low risk funds were better in some situations than the medium risk funds.

The voluntary pension fund market (Pillar 3) is significantly lower than the Pillar 2 market. At the end of February 2011 the asset under management of the Pillar 3 market accounted for 349 million RON and the number of participants reached 0,22 million. This market is expected to increase as a result of the tax benefits provided to the companies that offer a voluntary pension funds in the employees benefit packages.

The figure below shows the situation of the pension fund returns in December 2010. At that moment the returns of the pension funds showed a strong correlation between risk and return. But this was not the case in

all the time frames as a result of the market volatility.

Fig.2. The returns of the voluntary pension funds in December 2010.

Risk level	Voluntary Pension Fund	Return December 2010
Low	BCR - PRUDENT	8.0343%
	OTP STRATEG	7.4738%

	AZT VIVACE	14.8046%

Source: <http://www.csspp.ro/rate-de-rentabilitate/pilonul-3#>
Romanian Private Pension System Supervisory Commission (CSSPP)[6]

“The first step in controlling investment risk is the composition of the portfolio. Unfortunately, in order to bring about a low average contribution rate, a high percentage of capital needs to be invested in equities. In order to achieve stable contribution rates over time, a high percentage has to be invested in fixed-income assets. What fund managers try to do is to take advantage of the anticipated higher returns on equities on the one hand, whilst at the same time mitigating the effects of the correspondingly higher volatility. An additional tool is needed for this, and this is the buffer capital.” [2]

The Romanian Private Pension System Supervisory Commission (CSSPP) tries to impose regulations and to set investment constraints in such a way to minimize the loss risk of the participants. The Regulator’s importance is increasing more and more with the decreasing period until the benefits payments, i.e. the pension payments which will prove the quality of the investment decision made by the pension funds administrators.

5. Conclusion

The private pension system has as main goal to provide an extra benefit at pension age to sustain the state pension payments.

In the actual increasing trend of life expectancy the longevity should be a risk that the companies would be keen to take and be remunerated for while the individuals should aim to protect themselves against this risk.

The longevity risk impacts significantly the government, the individuals, the employers and the insurance/ pension industry and they will need to work together to find solutions for the wealth of a longer retirement period.

In the actual context the management of pension funds’ assets has to be thoroughly considered since the quality of the investment decisions will be felt even 40 years from now when the retirement benefits will be paid.

Views Regarding Floods in the Desnățui Plain and Their Effects upon Agriculture

Ciocan Elisabeta

University of Bucharest, Faculty of Geography,

"Simion Mehedinți – Nature and Durable Development" Doctoral School

eli.ciocan@yahoo.com

Abstract

Being delimited by the Danube River in the South, the Desnățui Plain was affected by floods, the most significant occurring in the year 2006, over the period March – April, as consequence of the water following reach fall-out and melting snows.

Agriculture on this area came to harm, being affected ploughable lands, lands occupied by grazing and meadow lands, but also the animals.

All these phenomena have had an obvious impact upon the farming production decrease which entailed in its turn a rise of agro-alimentary products prices.

Key words: floods, farming lands, the Desnățui Plain.

J.E.L. classification: Q190

1. Introduction

Water has had and still has an essential role in the life of plants and animals. Agriculture is an economic activity tightly related to water existence. The agricultural productions depend to a great extent on the required amount of water in the soil, provided by fall-out, on the phreatic water or, in absence of the best amount of fall-out, by means of irrigation systems, meant to settle this issue. Apart from the positive effects, water can be harmful for the agriculture, when fall-out is in excess.

The main hydrographic artery in the Desnățui Plain is represented by the Danube River, located in the south of the plain, which creates the main collector of the streams (the Jiu, Drincea, Balasan and Desnățui Rivers with its feeder Baboia) from the analysed area. This river is particularly important for agriculture practicing. Since the very

Antiquity was used as a means of transport in the cereals trade [1]. Currently it provides the required amount of water for the irrigations systems built-up on this plain area. Also, the Danube alluvial plain has provided the most benign lands to practice agriculture.

The Desnățui Plain is a region in which frequent droughts and floods occur as consequence of the climatic parameters variation during a year. They mirror in the either minimum or maximum rivers course.

The maximum course is caused by the water excess following rains (especially the pouring ones) or as result of snow melting. It is also called "high water" and it can entail high flood.

High flood represents the sudden and strong increase of the level of a stream determined by: powerful downpours, sudden melting of snow, superposed rains following snow melting, natural or anthropic dam breaking [2].

The most notorious high floods occurred on the rivers in the Desnățui Plain are those from the years 1954, on the Desnățui (at the Lipov hydrometric station), 1972, on the Jiu, Drincea Rivers (at the Cujmir hydrometric station) and the Desnățui (at the Goicea hydrometric station), 1976 and 1985 (in March) on the Jiu River [3].

The high flood in the year 1972 occurred over the period October 03rd – 31st and it had a unique character (mono wave), on the Jiu and Desnățui Rivers and multiple waves, on the Drincea and Baboia Rivers [4].

In the year 2006, high water caused ampleness floods with catastrophic effects upon agriculture.

2. Data and methods

In order to analyse the impact of floods occurred in the Desnățui Plain over the last

period of time, we have used data collected from different institutions, the Oltenia Region Weather Bureau, A.B.A Jiu (Jiu Water Basin Administration), Dolj I.S.U. (Dolj Inspectorate for Emergency Situations), Dolj Directorate for Agriculture and Rural Development (D.A.D.R.), that we have processed and interpreted drawing charts and maps.

3. Results and discussions

Over the period March 13th – 15th 2006, abundant rains and water resulting from snow melting had as result the overflow of both Danube River and Jiu and Desnățui Rivers (Fig. 1).

Fig. 1. The Desnățui River – Level recorded in 2006 at the Goicea hydrometric station

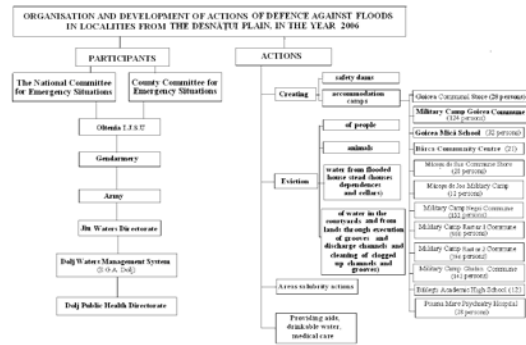

Source: A.B.A Jiu

The same year, on April and May, new overflows of the Danube River and its main feeders, Jiu and Desnățui Rivers occurred. This high flood on the Danube River affected a series of hydrotechnical constructions: Calafat Dam (3 km), Ciupercenii Noi (2 km), Piscu Vechi (0.2 km), Catane (11 km), Măceșu de Jos (0.8 km).

In order to remediate floods effects, representatives of different institutions participated in interventions (Fig. 2) as well as citizens from affected localities.

Fig. 2. The Desnățui Plain - Organisation and development of actions of defence against floods in the year 2006

Source: Dolj I.S.U.

There were evicted 7624 persons from Rast, Negoii, Bistreț, Cârna, Măceșu de Jos and Bechet localities, of which 5603 persons to relatives or other families, and a number of 2021 persons in specially arranged camps in the respective localities. Also, there were evicted 8800 animals from the risk areas.

Over the course of time, a series of localities from the Desnățui Plain suffered damages caused by floods (Fig. 3).

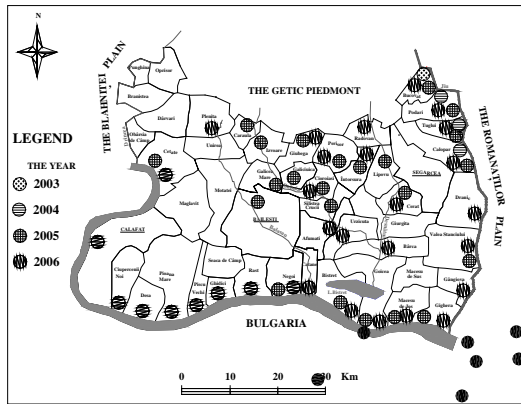

Thus, in the year 2003 floods occurred in Bucovăț Commune (April 13th – 15th), in the year 2004 in Calopăr, Țuglui, Podari Communes over the period June 01st – 13th, and in Podari Commune also over the period November 15th – 16th.

In the year 2005, 46% of the localities located in the Desnățui Plain were affected by floods, both over the period July 10th – 15th (Băilești, Bucovăț, Calopăr, Cetate, Cioroiși, Galicea Mare, Galiciuica, Giubega, Perișor, Siliștea Crucii, Țuglui) and over the periods August 10th – 15th (Bucovăț, Caraula, Cetate, Gighera, Giurgița, Goicea, Întorsura, Izvoare, Lipovu, Măceșu de Jos, Negoii, Perișor, Podari, Siliștea Crucii, Țuglui) and September 19th – 21st (Bistreț, Caraula, Cerăt, Goicea, Izvoare, Podari, Valea Stanciului).

In the year 2006, 62% of the administrative units from the studied area were flooded: Calafat, Afumați, Bârca, Bucovăț, Calopăr, Cerăt, Cetate, Cioroiși, Drănic, Gighera, Gângiova, Giubega, Întorsura, Măceșu de Jos, Negoii, Perișor, Piscu Vechi, Plenița, Podari, Radovan, Țuglui, Urzicuța, Valea Stanciului over the period March 13th – 15th, Calafat, Bistreț, Catane, Ciupercenii Noi, Desa, Ghidici, Gighera, Măceșu de Jos, Negoii, Piscu Vechi,

Poiana Mare, Rast over the period April – May 2006.

Fig. 3. The Desnățui Plain - Localities affected by floods

Source: A.B.A Jiu

Floods occurred in the year 2006 affected huge surfaces of farming land (Fig. 4).

Fig. 4. The Desnățui Plain – Flooded farming surfaces

Source: Dolj D.A.D.R.

The greatest damages were recorded in the territorial-administrative units in the south and south – west of the plain (Fig. 5), being caused by the Danube River overflow. Thus, the following localities are noted:

- Bistreț, 3435 ha of which 950 ha of farming land over the period 13 – 15.03.2006, and 2485 ha of farming land over the period 14 – 24.04.2006;
- Calafat, 2475 ha of which 1275 ha of farming land over the period 13 – 15.03.2006, and 1200 ha of farming land over the period 14 – 24.04.2006;
- Cetate, 2327 ha of which 1300 ha in the year 2005 and 1027 ha in the year 2006 (147 ha of farming land over the period 13 –

15.03.2006, 300 ha on 12.04.2006 and 580 ha of farming land over the period 14 – 24.04.2006);

- Ciuperceii Noi, 1850 ha of farming land of which 1050 ha of farming land, and 800 ha of pasture-lands;
- Desa, 1789 ha of which 1389 ha of cultivated farming land, and 400 ha of pasture-lands and meadows;
- Gighera, 1577 ha of farming land of which 117 ha over the period 13 – 15.03.2006, and 1460 ha over the period 14 – 24.04.2006;
- Măceșu de Jos, 3685 ha of farming land of which 400 ha over the interval 13 – 15.03.2006, and 3285 ha over the period 14 – 24.04.2006;
- Negoii, 2950 ha as follows: 150 ha of farming land in March of the year 2006 and 2800 ha of farming land of which 2300 ha of cultivated ploughable land and 500 ha of meadows on April.
- Piscu Vechi, 1387 ha of which 670 ha of farming land on March and 717 ha of pasture-lands and meadows on April;

The most affected was Rast locality, 6750 ha of farming land, of which 650 ha in the year 2005 and 6100 ha in the year 2006 (1600 ha over the period 13 – 15.03.2006, and 4500 ha over the period 14 – 24.04.2006).

Damages recorded in agriculture, as result of floods occurred from the year 2006 in particular, entailed a series of negative consequences upon the territory economy, among which we can enumerate low productions per ha and implicitly the rise of farming products prices.

Fig. 5. The Desnățui Plain – Flooded farming surfaces, by territorial-administrative units

Source: Dolj D.A.D.R.

Currently, over 2605 ha of farming lands from the Desnațui Plain are in areas with risk of floods (Table no. 1).

Table no. 1
Surfaces of farming land from the Desnațui Plain in areas with risk of flood

Item No.	Locality	Water Course	Farming land in areas with risk of flood (ha)
1	Afumați	Baboia	180
2	Bârca	Desnațui	400
3	Caraula	Baboia	200
4	Cerăt	Desnațui	300
5	Drănic	Jiu	100
6	Galicea Mare	Baboia	200
7	Lipovu	Desnațui	40
8	Motăței	Balasan	45
9	Podari	Jiu	350
10	Radovan	Desnațui	90

11	Siliștea Crucii	Baboia	400
12	Țuglui	Jiu	60
13	Unirea	Balasan	90
14	Urzicuța	Baboia	150

Source: Dolj I.S.U.

In order to prevent floods and for the geographic environment safety the following **measures** shall be taken into account:

- Permanent flow of latest information provided by the Craiova Regional Weather Bureau of the Operational Centre within the "Oltenia" Inspectorate for Emergency Situations with regard to the occurrence of potential meteorological phenomena that might affect population. In its turn, this institution notices the local committees, the social and economic objectives, for the purpose of taking the required measures.

- In order to remove damages caused by floods, there were built hydroameliorative arrangements with drainage role (channels) and drainage in order to remove the excess of humidity from the affected farming lands. Also, there were built dams along the following hydrographic arteries:

- The Danube, on the sectors: Calafat – Ciupercenii Noi – Desa, Ghidici – Rast – Bistreț – Nedeia – Jiu in the east as compared with Piscul Vechi locality;

- Jiul, Podari – Țuglui transom, on a length of 14.57 km;

- Baboia, dammed up on a length of 54 km and regulated on a length of 40 km in the area Caraula – Bârca;

- Another safety measure against floods consists of the building up of dam on Fântânele storage basin, with a length of 768 m and a height of 13.5 m. The basin is located on the Desnațui River, at the merging of the plain with the Getic Plateau, having a storage capacity of 25.8 mil. m³ and the role to protect a 1623 ha surface.

- Also, periodically, it is checked both the technical and the functional condition of longitudinal dams or of storages. Thus, in the year 2008, there were achieved additional earth moving and bring up to ground level of the Danube longitudinal dam, affected by floods of the year 2006, Ghidici – Rast – Bistreț facility (km 19 – km 15, earth moving volume 40.000 cubic meters) and it was checked both the technical and functional condition of Caraula storages (located on

Baboia brook, in the area of the locality bearing the same name, with fishing role and of protection against floods) and Bistreț.

- Forest shelter-belts in the areas dam – strand. After the floods from the year 2006, the Forestry Directorate performed an operation and maintenance program for the forest shelter-belt, especially for the shelter-belt located along the Bistreț – Nedeia – Jiu facility.

- Periodically, Dolj S.G.A. develops, through the waters management program, activities to maintain cleanliness in the beds areas and on the water course strands, acting so as to remove wastes and domestic residues dumps.

Abstract

Leasing is one of the activities which had suffered most during the crisis. Leasing business in 2009 fell by 72% compared with 2008. The volume of assets finance was similar with 2003, which leads us to conclude that leasing has regressed to 5-6 years. The decrease was observed in all transactions: fewer leasing companies, reducing the number of contracts, reducing the total amount, longer duration for expiring contracts. Leasing is one of the most used forms of financing that can appeal both individuals and legal entities. This is because they offer many benefits: tax - because companies can deduct the leasing, management - through careful planning money accessibility and speed compared to a bank loan financing for leasing services company.

Key words: leasing, crisis, lessor, lessee.
J.E.L. classification: G 32

1. Introduction

Leases had a flowering period, from 2003-2007, registering steady and consistent growth. This prolific period for the leasing market was driven by several factors such as:

- Increase of living has led to increased consumption.
- Increasing competition between leasing companies which made their offers to be increasingly more attractive for businesses, but also for individuals.
- Lack of regulations for non-banking

financial companies on the indebtedness of individuals.

- Ease the granting of financing by leasing companies who did not take into consideration the real possibilities for reimbursement by the customer or have overlooked or have not sought guarantees.

2. Evolution of the leasing market

For five years was a "golden period" for business leasing, by mid-2008 the gold began to lose its shine. Between Q3 2008 and Q4 2008, the leasing market has crashed by half, from transaction of 1236976000 euro to transaction worth only 637145000 euro. At the end of the year when the transactions were accounted, their value was 4817654000 euro.

Graph no. 1. Leasing market evolution

Source: www.alb-leasing.ro

The decline continued in 2009 when the market volume was 1333394000 euro, by 72% lower than in 2008. Value of assets financed under lease in 2009 ranged in value recorded in 2004 when the leasing market was 1384080000 euro [1]. Decline of leasing transactions expressed in all aspects: reducing the number of leasing companies, reducing the number of contracts, reducing the amount finance, the extension of ongoing contracts.

Romanian financial leasing market structure by customer type is: vehicles (transportation), equipment and real estate.

Graph no. 2. Romanian Financial Leasing Market Structure

Source: www.alb-leasing.ro

In 2009 equipment reached a share of 20% (261158000 euro), real estate 17% (232647000 euro) and 63% of vehicles (839589000 euro) [1].

The value of **equipment** financed in 2009 was down by 76% versus 2008. Construction equipment has the largest share of 22%, but it declined by 87% compared with 2008 due to suspension of several real estate projects. Area of farm machinery accounts for 9%, IT equipment and software at 8%, 8% is all the equipment for metallurgical industry, food industry equipment 4%, 5% of medical equipment, equipment for the woodworking industry 3%, chemical industry 4%, the rest being allocated to other categories of equipment.

Although every year **vehicles** have the highest share by type of assets financed, in 2009 the value was 75% less versus 2008. A decrease of about 72% was recorded in car

and light commercial vehicles, but the most dramatic decrease of 81% in 2009 compared to the amount funded in 2008, was in heavy commercial vehicles.

Graph no. 3. Romanian Financial Leasing Market Vehicle Financing

Source: www.alb-leasing.ro

In 2009 **real estate** financing was with 34% less than the amount funded in 2008. Financing was distributed as follows: 36% commercial and industrial buildings, office space 26%, land 4%, 6% were directed to hotels, 7% and 21% retail housing sector.

Experts consider that the conduct of beneficiaries changed due to the crisis. Users extend the contract and defer the decision to sign a new contract. In 2009 there were major changes in terms of the lease term. If in 2007 the most common period for the contract was 4-5 years (31%), in 2009 most of the leases (26%) were signed for a period exceeding five years.

Graph no. 4. Romanian Financial Leasing Market Structure by Duration of Contract

Source: www.alb-leasing.ro

3. Actions of leasing companies

Faced with the dramatic decline in market leasing companies have taken a series of actions to reduce losses:

Bad payer customers sued for recovery of assets. Application of this method is expensive and time consuming. In May 2009 Constitutional Court amended the procedure for enforcement of customer private economic agents who are bad payers. It is imperative for the leasing companies to obtain the declaration of enforcement from the court. This contributes to delays in enforcement proceedings. A good recovery can take several months during which the asset can not be executed. Delaying recovery of property contributes to lower their value and hence the impossibility of recovering damages in full [2].

Sale of goods under the value recovered. Leasing companies resort to selling recovered goods at lower prices than the amount charged for two reasons: the high cost of car parking and increase the number of cars recovered. The cost for a car "parked" in the car park is about 50 euro per month for a car. Losses can be high if the company vehicle fleet is 4-5 months in a car park. Romanian leasing companies reached over 10 000 cars in stock recovered from the customers that could not pay rates, according to estimates from market [3]. Intensification of competition, increased supply and low demand are reasons to determine the leasing companies to sell quickly the goods recovered.

Sale of repossessed goods abroad. Sale of goods recovered from bad payers is made in countries such as Netherlands, Poland, Germany, Hungary, Albania, Moldova and Slovakia. For example, Raiffeisen Leasing has sold in 2009 about 500 of 600 of the goods recovered, 95% abroad. Leasing companies sell cars in the country and abroad to "package" of at least four cars, at prices 40-50% low than the price originally paid in 2008 [4].

Diversifying of the ways of promoting assets repossessed. Along with traditional methods of promotion leasing companies strengthened promotion on the Internet. Some companies have set up special websites dedicated to resale of goods or created special sections devoted to repossessed goods

not only from Romania but also from other European countries.

Internal reorganization. To cope with the crisis leasing companies have gone through processes of internal reorganization to streamline the business. The measures taken concern: staff reductions, the calculation of life assurance, fleet management, changes in top management. Most companies have made changes in corporate governance. For instance three of the largest companies on the market UniCredit Leasing, BCR Leasing, Raiffeisen Leasing - have changed the top managers [5].

Tighten criteria for granting funding. Leasing companies tightened the criteria for selecting the users. To receive funding firms must meet a number of conditions including: delays not exceeding 30 days with the Central Credit Register and the Payment Incidents Register, to prove the existence of contracts in progress [6]. Individuals must demonstrate a stable employment and income in accordance with National Bank of Romania.

Registration in Central Credit Register. Central Credit Register (CCR) is a system specialising in the collection, storage and centralisation of information on the exposure of all reporting entities (credit institutions or non-bank financial institutions enlisted with the National Bank of Romania Special Register) in Romania to the debtors that were granted loans and/or incurred commitments whose cumulated value is higher than the reporting threshold (RON 20,000), as well as information on card frauds perpetrated by cardholders [7]. Leasing companies we're required to install and test the software purchased from the National Bank of Romania (BNR). The Benefit of registration in the CCR is that the credit report of clients can be verified. Before the imposition of these measures firms could be based only on good faith of the customers the declared value of their debt. Due to difficulties in carrying out the verification of financial statements leasing become attractive to many individuals who did not declare all debts taken. Also, leasing was attractive for those people who had the financial resources to pay the lease rate but had no evidence to demonstrate financial status.

4. Actions of customers

The economic crisis has made for some users difficult to pay lease rates on time or be unable to meet obligations under the lease signing. Some of these clients have adopted one of the following positions in relation to the leasing company:

Return the good to the leasing company.

Some users could not pay the rates and decided to return the property leasing company. Unfortunately, for the user unable to continue the contract, this is not a solution. Under the contract signed by the user returning the good does not automatically extinguish the obligations.

Transfer of the lease. Users who have difficulties in carrying leases have tried to find people willing to take over the lease. This means payment of the rates in exchange for the use of the property. Obvious application of this method requires the agreement of the leasing company which owns the good. It was created a site, www.cesiune.ro for those who wish to surrender a lease or are interested to take over an existing one, providing assistance during the entire process and multiple financing options. The site has signed cooperation agreements with a number of leasing companies: TBI Leasing, OTP Leasing, Ager Leasing, Tiriac Leasing. When taking over a lease advance and registration fees are already paid [8]. Person who takes property must pay a tax, which differs from a leasing company to another, but it stands at about 2% of the remaining payment, plus the rest of the remaining rates.

Good damage or declaring the property lost to fraud sponsor. In leasing the goods must be returned in same condition as taken into use. If the customer returns goods damaged, he must pay the necessary expenses to repair property. In addition, for damaging goods are legal consequences. In most cases, user undertakes, in the event of termination of his fault to pay all outstanding and unpaid bills and the rates until the end of the lease, including the residual value.

5. Solutions

There are solutions to overcome the difficult moments in the leasing market. Implementation of these solutions could be beneficial for leasing companies and for

users. Among the measures that may apply are:

- Creating partnerships between leasing companies to overcome the crisis.
- Providing financing solutions to areas less affected by the crisis. The most effective investments are in medical and agricultural equipments.
- Reduce of costs.
- Providing operational leasing contracts.
- Financing of niche segments: oil and gas.
- Providing second hand lease contracts.
- Careful analysis of the scope of the client seeking funding.
- Renegotiation of contract terms. Extension of contract and monthly payment of insurance are simple solution that will contribute at reducing the number of customers who can not pay the leasing rates.
- Flexibility in the relationship with customers.
- Training of staff. Implementation of the solutions presented above can not be done without a well-trained staff to meet the new requirements on the leasing market. Although cost savings is necessary and spending on personnel is not considered a priority in times of crisis, we believe that staff training should not be abandoned.

6. Conclusions

One of the problems of finance leasing market in Romania was a misunderstanding by the user of the real advantages offered by finance lease. In the Romanian leasing market many users have turned to leasing as a financing way to buy goods "unproductive". Leasing is ideal for a customer who needs a good and has no financial resources to purchase it. But, the goods financed by leasing must be an asset that "creates money", that means that the user must use the asset in a productive activity to acquire money. Thus, leasing is not an expense but an investment and leasing rate are paid by the user from the gain arising from the use of the good. Ease in providing financing by leasing companies has been beneficial on the short term, contributed to the growth of the amounts funded, but on long-term proved ineffective. Leasing a form

of financing for productive investment can be a recovery tool for economies drained by the financial crisis, that need strong and profound investments. Thus, states should encourage the financing of investment through the leasing of general interest in agriculture, food, chemical and mechanical engineering. Leasing combined with appropriate tax incentives can help the economic recovery.

Actual Financial Crisis - A New Phase of Economic Cycles

Ciote Cristina Steliana
„Spiru Haret” University of Constanta
cristinaciote@yahoo.com

Abstract

The present study, through substance and form, proves that contemporary academic interest for techniques to generate economic cycles is not a new one, but a continuation of old actions. As a result, have been sketched theoretical itineraries, convergent or divergent, designated to reflect the dynamism of studies about this thesis. We are aware that this topic is studied intensely, in all its complexity; therefore, our attention will be focused toward analysis of causes which have determined the actual financial crisis.

Key words: financial crisis, economic cycles.

J.E.L. classification: E20, E30, E32.

1. Introduction

During the time, the evolution of economic processes have been marked by „structural transformations in undulated form” [Iancu, 1, pp.210], personalized through some regularity and recurrence. Behind an endless and continued successions of transformations, in which one stage is, in the same time, the effect of the previous one and the cause for the next one, are hidden initial impulses (shocks), propelling forces, mechanisms of propagation. These cycles are in equal measure „causes and effects for some changes and adjustments of structures which produce not only losses, but benefits, arisen from actions for economic recovery” [Iancu, 2, pp.210].

Looking at economic cycles as delicate equilibrium between good and bad, we intend in this study to do research on shocks' line, shocks which generate disorders in economy, and change it course from good to bad. The relevance of this undertakes increases in time and space. Hence, we will take advantages from generous resources offered by recent

economic-scientific literature to help us to understand the origins of actual economic and financial crisis.

2. Theoretical Perspectives on actual financial crisis

The matter about the measure of deficient judgment of investors/players on financial markets has been in the middle of ongoing debate over actual financial crisis (and previous financial crises). We withhold here, for a better view over so many issued opinions, two analyses placed at opposite poles, some assigned to Gorton [Gorton, 3, pp. 466–472] and Stiglitz [Stiglitz, 4, pp. 281–296]. If the first author considers the crisis as a visible panic on a small segment of securities market, the second one point out that all the participants on the market are acting irrational.

The crisis brings in the light failure of corporate administration. Sahlman [Sahlman, 5] demonstrates that, in a big measure, the underestimate of financial risks, which has led to crisis, has been due because of loss of control inside the companies, misleading between concepts of accounting profit and economic profit and, not the last, special inside the firms with aggressive growth strategies, the appearance of executive and management structures which were not prepared to take the correct decisions.

The financial crisis and its effects above word economy give the representatives of behavioral school the occasion to contribute at understanding of such a significant event and to recommend remedies. Also, presents the opportunity of conceptual integration of behavioral economy and dominant economic theory and searching for new paths for behavioral and psychology economy. The articles born in this context provide analyses about origins and effects of crisis and in the same time intensify economic-psychological interdisciplinary approaches. A major

contribution is owed to Rötheli [Rötheli, 6, pp. 124–131], who describes the origins of financial crisis on mortgage and real estate markets from United States. He analyzes in detail the dynamic of collateral security of bank loans and the failure of rating agencies which, in general, underestimated the risks of bad credits. Furthermore, the text concentrates over limited rationality and political errors which have led to an excessive growth of credit. The work illustrates the possibilities of bank regulation and monetary politic and the improvement options for bank risk management as elements for upgrading of cycles of lending money activity in the future. The article ends with a suggestion for finding a compromise between stability and development within banking system.

In a large article, Lewis [Lewis, 7, pp.132–136] organizes his speech about causes of financial crisis on three levels. At the empirical manner, the author draws a range of psychological mechanisms implied in the origin of financial crisis. Based on cognitive and social psychology Lewis put himself between prejudices as "control illusion" and "money illusion", whose effects are amplified through contribution of other social factors. The reasons of failure can be described as a conflict between principles, but are mentioned and competitive economic debates regarding to crisis. In final, the relative admission of these ideologies by society is analyzed as a cultural phenomenon, and Lewis makes a pleading and suggests mechanisms to obtain equilibrium between two understandings of his own interest: a human tendency needed for an efficient market and an endless greediness.

A similar theme is carried on, by Leiser and authors team [Leiser, 8, pp.145–154] who investigate in an empirical mode the way in which the public understands causes and consequences of crisis. Based on an extensive national survey, the authors identify two fundamental approaches. The first one explains the crisis through a diversity of individual human weaknesses, pointing out cognitive and character deficiencies, which made the crisis, happened. The second idea, which is spread lesser than the first one, considers the crisis a systematic failure. Much more demographic variables temper these perspectives, special

the expansion at which the "player" has been affected personal by the effects of crisis.

In his critical article at the book "Animal Spirits" of Akerlof and Shiller, Shwartz [Shwartz, 9, pp. 119–123] analyzes ideas advanced by the two above mentioned authors, who are prominent economist researchers, with an excellent reputation since their contribution at the contemporary economic philosophy. The author treats the affirmation relating to macroeconomic phenomena, as business cycles and financial crises, which could be understandable only taking in consideration psychological factors as trust, persuasion, temptation, jealousy and illusion. According to Akerlof and Shiller a better macroeconomic analysis and a better politic of knowing limits of emotional factors and rationality. Among his affirmations, Schwartz makes reference to inertia which makes the progress harder in behavioral macroeconomic medium.

Taylor [Taylor, 10, pp.27] demonstrates using empirical methods that actions and interventions of American Government have caused, made longer and aggravated actual crisis. The main cause of crisis is represented, in his opinion, by remoteness from historic pattern and principles for setting of interest rate, which have been functional for 20 years. Governmental measures prolonged the crisis through a wrong diagnostic of issues in credit sector and through insufficient concentration on liquidity, besides concentration on risk control. These measures have conducted to more than the beginning and lengthen of actual crisis, but to its aggravation because of the financial support for various institutions and their creditors, on a lack of a clear and firm legislation.

Jagannathan, Schaumburg and Kapoor [Jagannathan, 11, pp.2] in the study "*Why Are We in A Recession? The Financial Crisis Is The Symptom Not The Disease!*" assign for crisis the quality of "symptom". The unprecedented growth of offers on labor market, initiated by geo-political events and technological innovations, as well as institutional incapacity to face this shock, created premises of macroeconomic discrepancy, which led to the big recession. The financial crisis from United States was the first sign which should has been treated. In the authors' opinion, a "healing" will be

possible only if the free circulation of capital from developed countries to undeveloped countries will be reestablished.

Rose and Spiegel [Rose, 12, pp.1-2] have been interested, foremost, to determine which of numerous and possible causes of "Big Recession" from 2008-2009 could be empirical tied by this. A significant number of causes have been suggested that being fundamental and potential reasons for global crisis which has begun in 2008. The researchers' approach was pure horizontal; any other credible theory of crisis should explain at least its impact at international level. The authors considered analysis at global level a simple and interesting exercise, from the moment that does not exist a consensus regarding to causes of crisis until the date of analysis. The researchers' judgment was that if, for example, the excessive evaluation of prices of houses has been the "fundamental" reason for the crisis - letting the freedom to be replaced with an exacerbate credit activity, the unevenness of balance of current account – this should explain the occurrence and severity of crisis in many countries, not only one. To find out the crisis most important causes would be more valuable to build a quantitative "early warning system" (EWS), like the one sustained by G-20 group. The authors appreciated that in a big measure their analysis was a failure, in the end they do not succeed to find an empirical pattern of crisis, which can bind any set of potential reasons for crisis with its manifestations. Their effort was a good opportunity to prove that rich countries have had regular economic failures; the same for countries with a significant growth on the securities market in the years before the crisis. Also, have been weak proves to show that the countries with tight commercial relationships with United States had crises less severe.

Claessens [Claessens, 13, pp. 247–264] and other authors tried to make a comparative analysis between actual financial crisis and other examples recorded by history. The author's team pinpoints three features regarding to contrast between actual financial crisis and the previous ones, each characteristics being treated as an answer to the next questions: "How much resemble the last crisis with the previous ones? How much

is different the last crisis to the previous ones? How expensive will be the last crisis?"

How much resemble the last crisis with the previous ones? Preceding period to actual crisis is characterized by four characteristics similar with the ones recorded in periods of previous periods of crisis. First, in the period before actual crisis, the value of assets has increased quickly in many countries. Second, in the same period, many key-economies recorded an increase of number and amounts of credits approved for individuals. Third, was happened a dramatic expansion in a diversity of marginal credits, special which can be met on mortgage market of advanced economies that led to an increase of systemic risk. Then, the regulations in financial sphere and the monitoring of financial institutions did not succeed to follow the development. These combined factors suddenly increased the risk of apparition of financial crisis.

How much is different the last crisis to the previous ones? The actual crisis has recorded new dimensions regarding to sternness level and the scale at which has acted, ending with incredible discontinuities and falls on many markets, in the 2008 fall. The crisis was different from the previous ones in at least four aspects. First, was recorded an exploitation on large scale of complex and obscure financial instruments. Second, the interaction between national, international and financial markets increased in a short period of time, and had in the middle United States of America. Third, the liability level of financial institutions increased. Also, the sector of goods and services sold played a central role. These combinations of new elements conducted to decline without precedent of sales in fall 2008 and ended in a global financial crisis.

How expensive will be the last crisis? The global financial crisis has aroused recessions in almost all industrial countries. Most of these recessions have been accompanied by crises of credits, by falls of prices on real estate market and severe financial crises. The recessions escorted by this kind of symptoms cause macroeconomic effects more expensive than ones without them. When recessions are accompanied by financial crises, the costs are much higher and emphasized for consume and investments.

Moshirian [Moshirian, 14, pp. 5-10] shows in a recent study that the difficulties

recorded in American banking sector because of excessive increase of bad credits caused chain effect of crisis toward financial sector of other countries, special European countries. The worsening of financial sector in United States of America and Europe have shaken national financial systems in different zones of the world and led to a global financial crisis. The article analyzes a number of rules and regulations which have been introduced since nineteenth century and argues the fact that most of national regulations, in the lack of global background and global property right, will drive often to more mediation actions of transcontinental regulations. The author explains that the "new international financial architecture" and regional and global financial regulations will give to a better global financial stability.

Moshirian sees in the latest universal financial crisis a unique opportunity for national and international organisms to reconsider many problems which have led to global recession and possible ways for amelioration of national and international financial systems. The study refers to another study revealed in 2009 by International Monetary Fund. This study show that recently universal financial crisis "revealed major flaws in actual global architecture". For this reason, International Monetary Fund identified four domains which need reforms: control of systemic risk, international coordination of macroeconomic effects of systemic risk, transcontinental agreements regarding to regulation of financial sector and financing for enough liquidities and external balance. Important to know is the fact that international financial organizations or international legislation cannot solve challenges on which is based a global financial market in continue expansion, without the upheld support of national financial institutions and without an harmonized national legislation with the international one.

Kenc and Dibooglu [Kenc, 15, pp.4-5] consider as major factors which contributed to financial crisis global macroeconomic disequilibrium, unsuitable practices for risk control and a fragile regulation and financial supervision. Probably because of financial globalization, asymmetrical distribution of business opportunities and demand for accumulation of some exchange official

reserves for prudential purposes, the global economy has known major macroeconomic disequilibrium since middle of '90. On one side, United States of America, Great Britain, Mediterranean countries including Portugal, Spain, Italy, Greece, Turkey and countries from Middle and East Europe have recorded big current account deficits, on the other side Germany, oil export countries and a couple of countries from Asia, inclusive China, Japan, South Korea, Taiwan and Malaysia have had current account surplus (International Monetary Fund, 2009). These disequilibrium together with capital flows carried to unbelievable low interest rates, practiced by European and American banks, encouraged a higher output and taking charge of high risks, based on complex, unclear financial instruments.

Fotopoulos [Fotopoulos, 16, pp. 8-18] is making a comprehensive review of myths about causes of actual financial crisis. It is remarkable the manner in which the researcher chooses to analyze in detail crisis causes, through their presentation from different perspectives.

Neoliberal ideologists identified as cause of crisis bankers' greediness and lack of scruples, who have put incorrect into practice the existent rules or have created derivative financial products to avoid to comply with these rules, only for the purpose of profit maximization.

In socio-liberal vision, the crisis, contrary the mythology supported by mass-media, did not conduct to a real "nationalization" of essential elements of financial system, like in the case of after war nationalizations. Political elite of United States and Great Britain evidenced in that moment that banks and other financial institution nationalization will be temporary, and should not be confused with past nationalizations, which had the tendency to extend social control in detriment of free markets.

According to left reformists approach, the crisis should not be attributed to "mean" bankers or speculators, but American neoconservatives and Anglo-Saxon neoliberals, who adopted neoliberal analyses of conservative economists (Hayek, Friedman, etc.). For the left reformist intellectuals, the neoliberalism is a simple ideology which, because of Thatcher and Reagan, was institutionalized through market

liberalization from '80 (inclusive financial markets) - a process that facilitated a "capitalism-casino". According to this idea, the neoliberal globalization "ideology" falls anywhere and the planned economy is back – illustrated today by banks "nationalizations" ("Brown Plan" put into operation these days in almost all central banks) and salvation plans (which are not new, have been put into practice since '80 and '90, during neoliberal globalization period).

In neomarxist approach, contemporary capitalist system is fighting not only with a financial crisis, but with three types of crisis: American imperialist crisis, the crisis created by emergence of multipolarized worlds and the crisis generate because of the pressure of actual economic growth over less and less resources. Financial crisis is perceived in terms specific Marxist image for over-accumulation.

3. Conclusions

In this study we nominated recent theories about causes which conducted to actual economic and financial crisis. At their level, we observe a convergence of opinions; economist researchers have considered that actual financial crisis has the roots in dramatic falls of house prices in United States or the collapse of credit market for houses, incorrect diagnosis of credit activity problems, wrong concentration on liquidity, and defective risk control. However, essential sources of financial crisis are deeper, not only by macroeconomic nature but microeconomic nature too, fact mentioned recently by many analysts.

4. Acknowledgement

This work was supported by the European Social Fund in Romania, under the responsibility of the Managing Authority for the Sectorial Operational Programme for Human Resources Development 2007-2013 [grant POSDRU/107/1.5/S/78342].

EU Actions and Progresses in Terms of Climate Change and Energy Policies

Ciote Cristina Steliana
„Spiru Haret” University of Constanta
cristinaciote@yahoo.com

Abstract

This paper is in line with the pleadings in favor with the need of transposition into facts of the seductive speech of sustainable development; the focus is on the normative field. Being aware that implementing sustainable development, multidimensional concept, require a full arsenal of tools and policies, we focused on the environmental issue around whom political concerns excelled, from the beginning until now. In a global world, with a “common future”, sustainable development policy agendas are varied and, sometimes, contradictory. Accused of partiality, our approach gets concreteness by the fact that it regards these agendas from the point of view of European Union (EU).

Key words: sustainable development, climate change, environmental policy, European strategies, greenhouse gases emissions.

J.E.L. classification: Q01, Q54, Q56, O52, Q57.

1. Introduction

This paper starts with a sequence of definitions dedicated to sustainable development, following the cadence dictated by the times of reference of the discussions on this topic. Starting from the title, we uncovered our intention to highlight unilateral made commitments, packages of measures and established objectives towards climate change that gives EU a leading role in this area. Much more and, perhaps, more important, we show that EU militates in favor of a strong global agreement and

legally binding, that enables effective participation by all countries in the fight against climate change, announcing its intentions to coordinate the cooperation in this regard. The paper presents an overview of the EU initiatives, actions and progresses in terms of climate change and energy policies.

2. Conceptualizing sustainable development

Sustainable development concept was advanced in Brundtland’s 1987 report in the World Commission on Environment and Development, suggestively entitled *Our common future*. The definition of sustainable development from the above mentioned report is: *that development that meets the needs of the present without compromising the ability of future generations to meet their own needs*. The report calls for reconciliation between economy and environment, aiming to identify “a development path that sustained human progress not just in a few pieces for a few years, but for the entire planet into the distant future” [****, *Our Common Future*, 4, pp. 4].

The concept was accepted and supported worldwide, being subsequently assumed in 1992 by the World Summit in Rio de Janeiro – *United Nations Conference on Environment and Development*. The conference proposed a concrete plan for implementing the sustainable development concept, called “Agenda 21”. Its replies “Local Agendas 21” would provide local governments around the world ideational support and

tools for the conceptualization and implementation of medium and long term sustainable development. The twenty-first century's challenges are reflected in national and global programs whose main action lines are the fight against poverty and social exclusion, sustainable production of goods and services, environmental protection.

Starting from the Rio moment, sustainable development is set to be a major project that aims for an ideal balance in the economic, ecological and social systems as well as their interactions. The multidimensional nature of the project itself and its implicit and explicit objectives raise next to the question of existence of an optimal, simultaneously economic, ecological and social, that of the difficulty of assessing the success or failure towards achieving these objectives.

On the same line of thinking it is placed the definition inspired and with a dense, yet warning message of Alan Durning: "a moderate level of consumption, together with strong social institutions and a healthy environment is an ideal higher than that of continued growth in consumption". In fact, this is the dominant note. Sustainable development is a concept that has inspired theorists from different disciplinary backgrounds, offering the satisfaction of a new creation, the founding of a different paradigm of thinking based on these principles. Sustainable development fits in complex action programs that invite to cooperation between today and tomorrow's people, between people which are the "product" of some particular cultures. Sustainable development needs its own ethics; in the absence of a "new" behaviour the development sustainability remains a nice dream of mankind at the end of the twentieth century.

In economic theory about sustainable development, *environment and environmental policy* enjoy a preferential

treatment. Ecosphere degradation rhythm provides the only explanation in this direction. There is even the danger that the predominant concern on environmental policy reduces too much the attention and the efforts required for solving the other problems that the phenomenon and sustainable development concept subsumes.

3. EU climate change and energy policies before and after

The Sustainable Development Strategy of the European Union (2001), as revised in 2006, is a framework for a long term vision of sustainability in which economic growth, social cohesion and environmental protection go hand in hand and are mutually supporting.

Committed to promoting a low carbon, knowledge-based, resource-efficient economy, EU has, in particular, taken the lead internationally in the fight against climate change, mainstreaming the objective of sustainable development into a broad range of policies.

3.1. What was the first step in the efforts regarding climate change?

The starting point of this analysis is the Kyoto Protocol, a landmark in the worldwide approaches in terms of sustainable development. Negotiated in December 1997 and ratified in October 2004, the Protocol required 141 signatory countries, including 30 highly industrialized ones to reduce the emissions of greenhouse gases by at least 5 per cent below 1990 levels, between 2008 and 2012. EU engaged to reduce emissions by 8 per cent compared to the same reference year. Protocol refers to the emissions of the three most important gases – carbon dioxide (CO₂), methane (CH₄) and nitrous oxide (N₂O) – which will be measured compared base year 1990 (except some countries, including Romania, that the base year is 1989).

3.2. What are the echoes of the Kyoto Protocol across Europe?

Goals and progress

By adopting some packages of measures and establishing appropriate policies, European progresses in achieving Kyoto Protocol's objectives did not fail to occur. By preparing free trade agreements and climate change activities, by developing innovative solutions by the member countries, EU has managed the integration of sustainable development strategy agenda in its foreign policies.

Eurostat report for emissions of greenhouse gases highlighted the progress made at European level. Some of these results are mentioned below.

Figure 1 – Greenhouse gas emissions and projections, EU-15 (index Kyoto base year=100)

NR: The projections are based on emission estimates up to 2006.

Source: (European Environment Agency)

Between 1990 and 2007, the EU-15 countries have reduced emissions of greenhouse gases by 5 per cent, leaving it 3 per cent from its reduction target for 2008-2012. Although emissions rose during the first few years of the century, they have been decreasing since 2004. Overall, between 2000 and 2007, emissions decreased, but at a slower rate

than over the previous decade. According to the projections made by the European Environment Agency, the Kyoto Protocol's target should be reached with the existing policies and measures. With additional measures, policies and use of the so-called 'Kyoto mechanisms' the EU-15 is expected to overachieve its target.

In addition to the Kyoto Protocol commitments for EU-15 countries, the EU is committed to achieve at least a 20 per cent reduction of its greenhouse gas emissions at the end of 2020, compared to 1990 levels. Until 2007, the EU-27 countries have managed to reduce emissions by 12.5 per cent compared to the same base year set by the Kyoto Protocol, but the major part of these reductions was achieved before 2000, which meant that emissions in 2007 remained at the same level as in 2000. Staring from what it has achieved so far and through its projections, the European Environment Agency believes that the chances of EU-27 countries to reach the ambitious target assumed by 2020 are reduced.

The above graph reflects two distinct trends within the EU. On the one hand there is a modest reduction of greenhouse gas emissions in the EU-15 countries, dominated by significant reductions made by Germany (by restructuring as a result of unification and changing preferences for other types of fuel than fossil ones) and by United Kingdom of Great Britain (by using electric motors at increasingly larger scale) which were canceled by significant increases of greenhouse gas emissions in other Member States and in certain sectors, such as transport. On the other hand, countries that joined the EU in 2004 - 2007, excluding Cyprus and Malta, have been marked by considerable reduction of emissions between 1990 and 2007.

There are a lot of examples that regard taking *concrete measures* by the European countries. France has committed itself to carbon-neutral investment with cohesion policy funds for the period 2007 – 2013. Another example offered by the United Kingdom of Great Britain is the allocation of carbon dioxide “budgets” to different departments. However, we see a lot of progress regarding the carbon dioxide accounting in companies, showing that the use of smart meters can lead to a reduction in energy consumption by up to 10 per cent. Some member countries have created new systems of energy auditing that contributed significantly to reducing energy consumption in the construction sector.

3.3. Can be done more than this? High EU energy and climate goals

The EU climate and energy package adopted in December 2008 sets ambitious targets at EU level. The EU committed itself unilaterally to *reducing by 2020 the EU greenhouse gas emissions of at least 20% below 1990 levels*, aiming also to increase the EU’s emissions reduction to 30%. EU also set itself the target of *increasing the share of renewable resources in energy consumption to 20% by 2020*, up from 8.5% today. The third objective of this package of measures was *a 20% reduction in primary energy use compared with projected 2020 levels*, by improving energy efficiency.

Agreement on the climate and energy package was a major achievement in the light of the economic crisis, being a preliminary stage of the Copenhagen Agreement. However, EU greenhouse gas emissions make up only a limited share of global emissions. While the EU is on track to achieve its greenhouse gas emission reduction targets resulting from the Kyoto protocol, global CO₂ emissions are today some 40% higher than they were in 1990, the Kyoto base year. It is estimated that in order to limit

the average global temperature increase to less than 2°C compared to pre-industrial levels, global greenhouse gas emissions must be reduced to less than 50% of 1990 levels by 2050.

3.4. Can cooperation be a solution? Another global approach of sustainable development through the Copenhagen Agreement

Although the *Copenhagen Agreement* has not satisfied Europe’s ambitions, it was a step forward towards achieving EU’s objective of signing a comprehensive, legally binding and global climate deal, which would take effect in 2013, when the Kyoto Protocol's first commitment period will have expired. As a clear manifestation of the political intention to reduce carbon emissions and to answer the climate change, both short and long term, the agreement has a worldwide support that gives the EU the opportunity to explore and to translate it into facts. Industrialized and developing countries, responsible for over 80% of global emissions of greenhouse gases have included so far in the agreement their own objectives or actions in terms of emissions. The discussions were completed with significant progress in negotiations about the needed infrastructure for the proper functioning of the global cooperation on climate change, even including improvements to the Kyoto Protocol.

3.5. Time is not on our side!

Among the *post-Copenhagen* measures, urgent realization of the EU’s commitment to annually provide developing countries a quick initial financial assistance of 2.4 billion EUR, between 2010 and 2012, is essential to enhance the credibility of the EU as well as the recipient countries’ capacity to cope with climate change. Moreover, EU’s further efforts towards a better

development of international carbon market, are essential to encourage low carbon emissions technologies and to reduce global emissions cost-effectively, carbon market being able to generate major financial flows to developing countries. Enhancing cooperation for a global agreement on climate change supported the adoption of specific and pragmatic decisions at the United Nations Climate Conference in Cancún (Mexico), scheduled between the 29th of November 2010 and the 10th of December 2010.

Among the new challenges of sustainable development are energy security, climate change adaptation, food security, land use, public finances sustainability and the external dimension of sustainable development. Along with achieving the millennium development goals, climate change and energy should remain priority areas.

Kyoto Protocol remains the main element of the climate change process conducted by the United Nations, but the limited number of signatory countries and its serious deficiencies are still problems that must be solved. Not solving these deficiencies related to forestry emissions accounting rules and to the national management of unused carbon dioxide emission rights between 2008 and 2012, would invalidate the current commitments of industrialized countries in reducing emissions.

4. Conclusions

Trying to present the progress made by EU policies in areas affected by sustainable development strategy provides future topics for reflection. The joint efforts of the world states, done together or by region, aim to start a long transition process of the socio-economical system on the current trajectory, which is already in the critical zone of the ecosphere support capacity limits, on a new trajectory of sustainable socio-economic development, incorporated within these limits

.This paper stresses that, despite the considerable efforts done in order to maintain sustainable development on this trajectory, many trends remain unsustainable. So, the challenge that remains is identifying the viable solution to the inertia that characterizes the actual movement of socio-economical systems. In our opinion, the force that can "reverse" the current trends and put them on the correct track is cooperation between people of a world without borders, today and tomorrow people, which consciously or not, are engaged in the struggle for life insurance. Formally expressed, the sustainability of development remains a natural extension of the international consensus in terms of measures, policies and strategies.

Mergers and Acquisitions – an Incipient Field in Romania

Ciotină Daniela

Fădur Cristina-Ionela

"Alexandru Ioan Cuza" University Iași, Doctoral School of Economics

ciotina_daniela@yahoo.com

cristina.fadur@yahoo.com

Abstract

Purpose – This paper is a review of specialized literature concerning the merger and acquisition processes, both worldwide and in our country, expressing a personal point of view on the evolution of this phenomenon.

Methodology – with this article, we have attempted to achieve a compilation and an interpretation of the directions followed in specialized literature after performing academic research in the field of mergers and acquisitions (M&A).

Conclusions – although the analyzed phenomenon has continuously developed for a long time at the world level, in Romania we can speak of an incipient period of the merger and acquisition processes

Key words: mergers and acquisitions, economic crisis

J.E.L. classification: G34

1. Introduction

The topic of mergers and acquisitions has developed continuously from the viewpoint of the investigations performed in specialized literature in the past two decades [2], as a result of the increase of the number of mergers and acquisitions worldwide, as well as of the development of the complexity of this phenomenon.

As the economic crisis has deepened, financial markets are subject to a volatile and insecure environment, entering a vicious circle of debt redemption through sales of assets and price drops. This situation determines an increase in the number of mergers and acquisitions at the world level. The M&A activity is one of the solutions that governments can resort to in the current

context. 2009 was a year when giant bids diminished and smaller bids were encouraged, so that very large companies have acquired their competitors, weakened by the collapse of the credit market [19].

The reason that supports the merger and acquisition processes is that two companies together are more valuable than two separate entities. The alchemy of a merger or acquisition can be described by the following statement: one plus one is three. The objective of any such transaction is to create a higher value than the sum of the values of the two merging companies.

This article presents in short the merger and acquisition concepts, a structure of mergers and acquisitions, and the stages of the M&A process.

2. The Process of Mergers and Acquisitions – at the World Level

In a broad sense, mergers and acquisitions can involve a various number of transactions, from buying and selling companies, concentration among companies, alliances, cooperation, and associations in participation in forming companies, corporate succession, ensuring the business independence, buy-out and buy-in management, modification of the legal form, initial public tenders, and even restructuration [14]. However, the use of a broad definition of M&A could lead to confusion and misunderstanding, since it involves everything from mergers to strategic alliances [16].

The two terms, mergers and acquisitions (M&A), are normally used alternatively in strategic investment decisions, and a distinction between the two notions is necessary. Mergers imply two entities relatively equal in size, which create a new company by combining all that is best in both entities. An acquisition is a process much

easier to achieve, implying the development of an already existing company by combining it with a much smaller one [19]. An acquisition means buying shares or assets from another company in order to gain an influence on its leadership, and this transaction is not necessarily made in mutual agreement [15].

There are numerous causes why a company chooses to merge or to acquire another company. Specialized literature suggests that mergers and acquisitions are the result of a series of reasons and arguments. These reasons span from considering mergers and acquisitions as a motivated implementation of the strategic intentions up to caprices and egotistic manifestations of the management of companies with a very good financial position.

In the current business landscape, when the large swallow the small and the weak let themselves be bought by the strong, there appears the opportunity to acquire prestige companies at a reasonable price. In the context of the world economic crisis, mergers become a need, not a luxury.

While the last years of research have witnessed the intensification of the human and psychological aspects of the implications of the M&A process [4], specialized literature continues to be dominated by financial and market studies with a high concentration of the interest in the USA[5] and the Great Britain[3].

At the world level, there is a classification of the merger and acquisition processes. From the perspective of the earned value, they can be vertical, horizontal, and conglomerate. Vertical integration is obtained by the merger between a company and its providers. Horizontal integration appears when two companies that activate in the same field merge in order to improve their combined value. Mergers by conglomerating appear when the companies that participated in the merger continue to develop their activity in different fields and sectors[8].

According to the type of relations involved, mergers and acquisitions can be "amiable" and "hostile" [14], and according to the economic space, they can be domestic and cross-border[1]. Cross-border mergers performed between 1990-2000 in the United States of America have had a positive effect

on the economy of this giant of the Globe [12]. Another classification given to this phenomenon, according to the same criterion, splits mergers and acquisitions into external and internal [7].

A study made on a sample from 49 countries has showed that a higher protection of the investors is associated to a larger number of mergers and acquisitions, more hostile undertaking attempts and a reduced number of cross-border bids [20].

Other studies provide new directions in the cross-border M&A category, of which some give the possibility of an optimal selection of the target companies (companies that will be acquired) even from the pre-merger evaluation stage, while others provide a summary of the limitations in this field, in the limitation reporting segment, but both are important in studying the autochthonous industrial diversification [10].

A typical M&A transaction goes through three stages: planning, implementation, and integration. In the planning stage, a global plan is developed for the transaction, in the most inter-disciplinary and broad way possible. Planning covers operational, managerial, and legal techniques aimed to improve the following two stages. The implementation stage covers a series of activities starting from issuing confidentiality or non-disclosure agreements and the letter of intent and ending with closing the contract and completing the M&A transaction. The last stage is concerned with ensuring post-deal integration [14].

A similar model is the Watson Wyatt Deal Flow introduced by Galpin and Herndon (2000), two practitioners at Watson Wyatt Worldwide. Their model decomposes the process into five smaller stages, which are: formulation, localization, investigation, negotiation, and integration. Moreover, Aiello and Watkins (2000, in Harvard Business Review 2001) suggest another model that describes the merger and acquisition process. However, this model outlines only stages in the transaction negotiation process, which in its turn is covered by activities in the pre-agreement stages dealt with by the Watson Wyatt Deal Flow model[14].

Of the three mentioned models, we consider that the most relevant in studying the merger and acquisition process is the

Watson Wyatt Deal Flow model, since it includes the most complete image of the way in which the merger and acquisition process is organized.

In the research field, the merger and acquisition process has largely developed along disciplinary lines, and finance specialists relied mainly on the problem of value creation or reducing the shareholders' wealth after an acquisition. The multitude of proofs shows that, although company acquisitions bring positive results on the short term for the associates of the target companies, the long term benefit for the investors, in the case of a company acquisition, is disputable[5]. Approximately 35-45% of the buyers reach positive values in the 2-3 years preceding the transaction, with a computed standard deviation of 10% around the average [9].

The wish to understand the antecedents of this variance is at the center of research in the M&A field and is the subject of the first article on this issue. This paper takes into consideration the pulse of the bid and investigates the tender effect: friendly, hostile, the white knight, or very hostile, based on the long term performance of 500 acquired companies in Great Britain, through the analysis of a shareholder in various moments over a three-year period. In spite of the negative tenders they receive, the authors claim that their results show that the tendered amounts by a single hostile bidder will have a higher financial performance than that of a friendly bidder, of a white knight, or of very hostile bidders [22].

In specialized literature there also is a time division of the merger and acquisition processes, the so-called "merger and acquisition waves". The first wave (1893-1904) was characterized by horizontal mergers and consolidations, with the purpose of eliminating competition. This is how giants in the field of steel, telephony, oil, mining, railroads, etc. were formed. The second wave (1919-1929) is marked by the adoption in 1914 of the "Clayton Act", an additional instrument through which the authorities attempted to prevent unprofitable mergers. The third merger and acquisition wave coincides with the period of economic prosperity in the USA (1955-1973) and is characterized by conglomerate mergers. Ronald Regan's presidency corresponds to

the fourth wave of mergers and acquisitions (1974-1989), a period when a multitude of either friendly or hostile mergers took place, reaching values of billions of dollars. The fifth wave (1993-2000) followed the economic crisis of 1990-1991, and was mainly characterized by hostile mergers, and the mergers performed through indebtedness were ever more reduced [21]. We could also delimit the beginning of the sixth wave of mergers and acquisitions, after the start of the global economic crisis at the end of 2008 – the beginning of 2009. The negative effects of the financial collapse period have determined an increase in the number of mergers and acquisitions.

In the context of the current economic crisis that has shaken world's economy, mergers can be regarded as a process exterior to the company, a way of attracting foreign investments with the purpose of surpassing the difficult period generated by the economic crisis.

The merger and acquisition activities have significantly increased all over the world in the last two decades, and the value and volume of mergers and acquisitions attained new records. There appeared the need to create large entities, able to become the main pillars of an economy subject to permanent change, companies that would ensure a constant and sustainable economic development for themselves, an objective that can be reached by combining resources and technologies through mergers.

3. The Merger and Acquisition Process – in Romania

We can state that Romania is still in the spade work stage in what concerns mergers and acquisitions. According to some authors [11], mergers are considered the classical form of restructuration, and according to others [17], they are a form of capital concentration (economic, technical, human) in the view of the survival or development of two or several entities on the competition market. Unlike other forms of concentrations, the consequences of the merger are: creating a new company with a distinct legal personality, reuniting the patrimony of the participant companies instead of transferring liquidity or intangible assets to companies under different forms of association.

If in foreign specialized literature a distinction is made between mergers and acquisitions, Romanian legislation defines and regulates mergers through absorption and mergers through consolidation.

Mergers through absorption, characterized by the fact that one of the merging companies continues to function as a legal entity (the absorbing company), while another (absorbed) company or several companies will transfer their patrimonies (assets and liabilities) to the absorbing one, ceasing their existence as legal entities. The second variant corresponds to mergers through consolidation, which implies the legal extinction of the merging companies and the appearance of a new one, which takes over the patrimonies of the extinct [13].

From an economic point of view, a traditional classification can be made between [23]: mergers-annexations – characterized by the supremacy of one company over another and consisting in power and control transfer through patrimony mutations. From a legal perspective, this type corresponds to the merger through absorption; mergers-combinations – characterized by an alliance between two or several distinct entities with the purpose of creating a new entity. This type of merger corresponds from a legal viewpoint to the merger through consolidation; internal restructuring – its objective is to legally remodel power within a group without changing the dominant control and modifying the internal organization in order to meet the imperatives of economic development.

In the period of manifestation of the financial crisis, the number of mergers and acquisitions in Romania has considerably increased in comparison with the 10 years before the crisis, while in other European countries (Great Britain, France, Germany, Italy, Croatia, Bulgaria, the Czech Republic, Hungary, Poland, Greece) the number of mergers and acquisitions has not raised. Based on this information and in combination with the difficult situation of most companies, the Romanian market has become attractive both for foreign investors and for local ones. In comparison with the other analyzed countries, the number of closed mergers and acquisitions is still very low, the

only countries that are on a lower position being Croatia and Bulgaria [6].

4. Conclusions

In our country, the merger and acquisition process is still in an incipient stage both in the field of academic research and at an empirical level.

In the economy of the new millennium, an intensification can be seen in the rhythm of the merger and acquisition processes. In this new context, it is necessary to stress the modeling processes based on typological structures of the relations established between the companies existing on the market. Strategic planning develops long term approaches in the market mechanisms and is an instrument that allows the company to "better navigate in a continuously changing market environment" [18].

The national economic environment could affiliate to the world level tendencies: small and medium enterprises will be able to survive by combining their material and financial resources, through collaboration projects and mergers.

Tendencies in Tour-operator's Distribution Channels Portfolio

Ciuchete Stela Georgiana
Academy of Economic Studies, Bucharest
georgiana_ciuchete@yahoo.com

Gheorghe Camelia Monica
Romanian-American University, Bucharest
gheorghe.camelia.monica@profesor.rau.ro

Abstract

Tour-operators had to change their business model in order to adapt to the new e-mediaries in the travel industry. Besides distributing their products through the traditional travel agencies that can provide much more customized information by gathering and organizing information in a unique manner for their customer's travel needs, they can also distribute online as the Internet has created a new competitive business environment in the last decade.

Key words: distribution channels, tour-operators, travel e-mediaries

J.E.L. classification: L 83

1. Introduction

There are two ways in which a company can promote and supply its services to customers: the direct travel distribution channel when services are delivered directly to consumers and the indirect one that implies at least one mediate in between responsible with one or more channel functions. Most of the companies that activate in the tourism industry use more than one travel distribution channel, each one operates in parallel to or in competition with other channels, in order to reach as many clients as possible (Fig.1).

The distribution mix in tourism is seen as "the combination of the direct and indirect distribution channels that a hospitality and travel organization uses to make customers aware of, to reserve and deliver its services. If wholesaler travel agencies know the effectiveness of their marketing distribution mix, then they can implement strategies to

enhance market share and profits for the most effective distribution channels [1].

2. Traditional travel distribution channels

Tour operators are businesses that combine two or more travel services (e.g. transport, accommodation, catering, entertainment and sightseeing) and sell them through travel agencies or directly to final consumers as a single product. A tour operator is thus a crucial link in the distribution chain, representing the central connection between customers and providers of tourism services, and thus has the power to influence both the demand and the supply side.

Tour-operators connect suppliers in the tourism value chain by assembling various elements of a holiday trip into one package that is sold to the consumer. On the one hand, the tour operator serves as the sales office of individual tourism service suppliers. It has the knowledge of market trends, provides front-end and promotion budgets, and accepts a part of the risk of primary suppliers.

Because operators buy tourism products in bulk, they benefit from scale economies and can offer whole packages at prices that are usually lower than consumers could negotiate individually.

Tour-operators can be classified into two main categories:

- Wholesale operators – the creators and organizers of travel packages sold exclusively through retail travel agencies.
- Direct operators – they do not sale only through retail travel agents, but also directly to the customers.

The two terms: wholesaler and tour-operator are used interchangeably both in tourism literature and industry practice as

tour-operators take the wholesalers place and vice-versa.

Retail travel agents are responsible for the sale of a range of travel products. The travel agents have moved away from over-dependence on airline commissions in recent years, concentrating instead on more lucrative market segments like cruises, tours and vacation packages.

While travel agents are still the airlines' main channel of distribution, it is the most expensive method of ticket distribution.

Airlines can sell directly through their sales offices, call centers, own website and to corporates. The indirect channels which are open to them are traditional travel agents; on-line travel agents; on-line travel portals; tour operators and consolidators. The indirect channels are backed up by Global Distribution Systems (GDSs) [2].

3. Travel e-mediaries

Consumers can undertake their entire tourism product search and booking online and therefore, the role of intermediaries has been changing dramatically. The Internet is widely used to deliver up-to-date content. As a result, Buhalis and Licata (2002) refer to the new distribution channels driven by the Internet as the new tourism "eMediaries"[3]. Travel providers took advantage of the new online business opportunities and allowed consumers direct access to their reservation systems.

- Airlines and hotel chains websites (ryanair.com)

- Online travel agencies(Expedia.com, Travelocity.com, Ebookers.com, Orbitz.com) - collect information from the customer (e.g., departure and arrival destinations, preferred flight times, and number of travelers). This information is submitted to a computerized reservation system (CRS), which searches for relevant flights from the compilation of offerings from participating airlines. The agency then processes the information provided by the CRS and presents it to the customers in the form of an itinerary schedule. Once the customer chooses the most suitable travel itinerary, the online agency processes the booking through the

CRS and receives a commission from the airline in return.

- Internet portals (Altavista) and vertical portals (vortals – portals conceived for a certain industry or research area) also have developed online travel distribution, often by sourcing their travel content from external online agents and suppliers (ski.com, golfonline.com, tennis.com)

- Online last minute agencies (lastminute.com) managed an efficient distribution of all offers that reached the deadline of sale. Priceline agency was the first to introduce a search engine that enabled clients to select travel providers by the budget allocated for their holiday.

- Media trusts, publications and TV channel networks (cnn.com/travel)

- A number of sites (ebay.com) specialized in the sale of distressed stock through auction.

- Social networks (facebook.com, mySpace.com). According to Facebakers (<http://www.facebakers.com/>) there are (as per the month of December, 2010) 2,5 million Romanian Facebook users, 33% of the online population. More and more Romanian travel providers made their own facebook webpages thus changing their online travel approach to consumers.

- Review sites (Tripadvisor.com, Travelpod.com, Travelblog.org) – enable consumers to exchange information, opinions and recommendations about destinations, tourism products and services, with sometimes diaries of travel experiences and ratings of a particular product or hotel.

- Podcasting and vlogs (online videos: YouTube, LonelyPlanet, Travelistic - video sharing)

- Microblogging has taken the concept of blogging and compacts it. Conventional blogs can be of any length but microblogging is carried out usually by mobile phone text messages and is therefore currently restricted to just 140 characters. Twitter is possibly the best known microblogging site and was launched in 2006 although other sites include Jaiku and Pownce. Users post messages to the site via the web or by text message and these "tweets" are forwarded onto their network of friends and contacts.

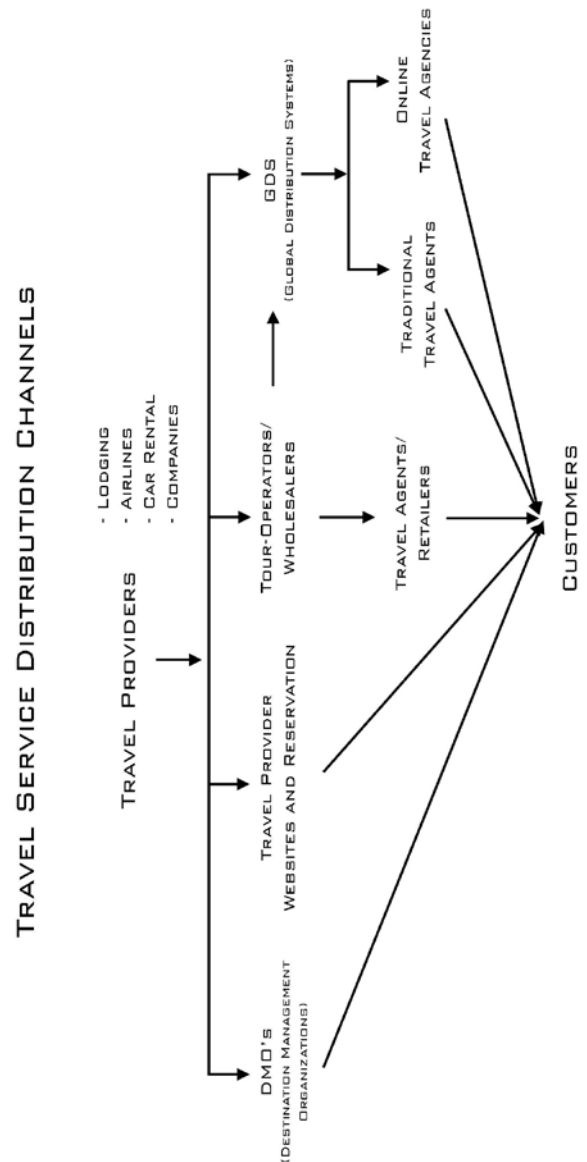

Web 2.0 and online social networking websites heavily affect today most of the online activities and their effect on tourism is obviously rather important. Tourism organizations were some of the first to utilize the resources of the internet, but in the last few years a further "revolution" has impacted the way we communicate, work and conduct business. The buzzword for this is Web 2.0 and appears to have enormous potential for tourism organizations.

4. Conclusions

To remain competitive, tour-operators have to permanently examine all the marketing distribution channels and insure of their use at a maximum level.

Tourists and travelers have at their command online resources which enable research of possible destinations, transportation, accommodation and leisure activities, and enable the online purchase of these products and services. This is nothing short of a consumer revolution which has effectively transferred much power from suppliers to consumers, as the internet further expands and modifies into the Web 2.0.

The Public Pensions System, Where To?

Ciuraru-Andrica Cristina
„Vasile Alecsandri” University of Bacau
cristinaciuraru@yahoo.com

Abstract

We are well aware that, sooner or later, we will have to wear the “coat” of old age. Whether old age will be burdensome or not, or whether we will have bigger or smaller “pockets”, it is certain that we will have to wear this “coat”, even with dignity and pride.

This imposes a favourable and motivating context offered, first of all, by that entity which must ensure the wellbeing of its citizens, namely the state. However, nowadays, this idea becomes more and more out-of-date, considering that the state itself questions “the security of old age”.

If it is, currently, almost unable to offer a decent pension to those who have contributed for years to the public pensions system, what level of credibility could it ensure for the future pensioners?

Key words: pension, the Public Pensions System

J.E.L. classification: H55 - Social Security and Public Pensions

1. Introduction

The problem of the public pensions systems, faced by many states, including Romania, arouses the thoughts and imagination of those directly involved, leading to more or less gloomy scenarios.

The current pensioners probably ask themselves when the government officials will come to realise that the pension is a right for which they have contributed their entire life, while now they only get back what they have given (maybe more, or maybe less), and that they will still have to fear that the “pensions tap” could dry up or get empty in any moment.

The insured persons (as well as other categories of persons insured at their own

initiative), who are, inevitably, loyal contributors to the public pensions system, also wonder, and they are right to do so, how, after years of work and financial support of the current insured persons, they will be, in their turn, “rewarded” at least to the same extent. It would only be normal for this to happen. However, the daily reality reveals a totally different perspective.

These aspects, and many others, still remain unsolved.

Consequently, we can only find valid solutions that could build up a “Salvation Arc” for the Public Pensions System.

2. Indisputable causes

The budgetary deficit for social state insurances, the increase in the relation number of pensioners - number of employees from year to year etc. are only a few of the hotly debated subjects, which cause discontent and disappointment among the population.

This current situation of the public pensions system in Romania, as well as in other countries, is not only the consequence of the economic-financial crisis which is so much debated by the media, but it is also the result of abuses along time, or of inherent situations which are impossible to control and amend.

Hence, the deficiencies of the public pension system in Romania are based on a series of causes, which have been intensely interrogated and analysed, and which could be classified as subjective and objective causes.

Subjective causes have led to divergent opinions.

The people who oppose the private pensions system consider that the blame for the crisis in the public system must be put on the transfer of a part of contributions for private administration, causing deficit in the pensions budget, which needs covering

(generally, by transfer from other budgets), leading to an increase of the deficit in the general consolidated budget.

Most accusations are, nevertheless, directed at the abuses in the system, which are attributed to the government officials, starting right after the Revolution in 1989. Some of them are:

- covering other deficits with money allotted to pensions in cases when the corresponding budget was in excess;
- avoiding unemployment by anticipated retirement, which led to the rapid increase of the number of pensioners as compared to the number of employees;
- increasing the pension amount, especially in pre-electoral periods, while the pensioners were manipulated by means of promises that lacked economic foundations, as a result of politicians' strong personal interests in acquiring power and profit;
- granting special types of pensions or benefits attached to pensions, which were exaggerated as compared to the ordinary ones, and which were entitled to some categories of persons who had previously worked in various domains or areas that were considered "more special" than the others;
- unclear and incomplete regulations in the field, permitting divagations and omissions, highlighting the vulnerability of the system etc.

The amendment of the situation was based on an increase in social contributions, which led to subsequent encumbering for the active ones. The result of this measure was not the one expected. The budget revenues did not rise, on the contrary, they diminished. Why? Because this encouraged illegal work and, more than that, a significant part of the young active people immigrated. We can also observe the increase of the unemployment rate, the outcome of the employers' impossibility to "survive" in times of crisis, and of the heavy fiscal burden, resulting in a continuously diminishing number of contributors.

Among the objective causes we can identify:

- "the demographic boom", namely the continuous rise in life expectancy rates as opposed to an alarming decrease of birth rates;
- increase in population aging rates (a problem in entire Europe, not only in

Romania), which leads to an ever-smaller contributors – pensioners rate (statistics for our country, in connection to the evolution of the number of inhabitants, are not satisfactory, since this number decreases from year to year).

- decrease in birth rate and, because of this, the percentage of the young population within the total number of the population is very small, while this will negatively affect the future, if this pension system, a 100% redistributable one, will be maintained.

All these causes, if corroborated, lead to distrust in the public pensions system, and to uncertainty as related to its capacity to guarantee a decent pension in the future.

As a result, this system on which the state depends (named, in specialized literature, the "pay as you go" system, according to which the collected money is immediately distributed, and it still is insufficient) can no longer operate on sustainable grounds for too much time.

3. Possible solutions?

Therefore, in order to avoid the collapse of the public pensions system, which seems more and more inevitable, pertinent and credible measures must be taken, which will amend its sustainability and durability by way of efficient management of its available resources, as well as of future ones.

There are multiple possible solutions to the problem described, but it is a matter of proving which of them is most likely to be implemented, or which has more chances of success, so that the current crisis of the public pensions system could be a mere story of the past.

1. Encouraging the private pensions system which, according to statistics, even in times of economic crisis, has obtained very good results.

Disappointed with the state system, many contributors show greater trust in private pensions associations, and this is enhanced due to the fact that they offer a series of pertinent security measures which are meant to support the guarantee for invested funds. Therefore, we should accelerate the process of increasing the percentage of contributions to the private sector.

2. Increasing the retirement age and the due period.

Certainly, this measure could be seen as anti-populist, and thus undesirable, but it is in agreement with enhancing life expectancy at old age, so this could be a viable solution, even if it may find some contesters.

3. Increasing employment rates among old people.

This measure is accepted by some, unaccepted by others, but it is closely related to the same reality of enhancing life expectancy at old age.

4. Using a part of the budget for the public pensions system for productive investments.

This way, the public pensions budget could be justifiably named pensions fund, of a non-redistributable type (which means that what is accumulated is also distributed), a new one which could accumulate a lot more as a result of efficient and, hopefully, profitable investments.

5. Issuing viable and thorough regulations regarding pensions, which are intended to restore realism and sustainability in the domain of state pensions.

This is an imperative measure not only for pensions system, but also for concurrent sectors. Only by doing this could we build a pertinent, correct, transparent and unimpeachable system. Nevertheless, this depends on the competence and willpower of "the important" ones, but its feasibility is unquestionable.

6. Solving the problems concerning workforce competitiveness (increasing productivity).

This solution should be applied to all levels, from the smallest firms located in street corners to great corporations, but for this to become viable, the motivation of each employee is extremely important. How are employees motivated when the contributory burden is heavy, even unbearable and, more than that, expectations for at least a decent pension are almost futile?

7. Unifying the pensions system so that everybody pays the same contribution, while the pensions are calculated in a unitary manner for all pensioners.

This way, the great discrepancies that have led, along the years, to controversies and disputes – or even to suspicions and accusations concerning the functionality of the public pensions system – would disappear. This inequity was supported for a long time by the existence of the category of

special pensioners (even if these pensions were not covered completely by the budget for social state insurances), among whom, paradoxically, the deciding agents could also be found, while they clearly favoured these types of pensions. On the other hand, it was also supported by the numerous group of "insignificant" people. By virtue of the equality principle, which lies at the basis of the organization and structure of the public pensions system, this inequity must be abolished, by all means, from the present governing policy which claims to operate in the service of the citizen. The new pensions law (263/2010) took a first step by eliminating special pensions and by including certain categories of people (with a previous special status) in the unitary public pensions system (public clerks, clerks with a special status, military men, policemen etc.).

Certainly, other solutions could also be added to the ones above, but we consider that all these could be unified in a single solution, namely that of creating an efficient collaboration /alliance between the private and public system in order to create a pertinent and credible pensions system.

4. Conclusions

Our optimism urges us to observe that the elaboration or at least the improvement of the existing public pensions system is possible, even necessary without delay. A functional and efficient public pensions system could renew the contributor's and pensioner's vision, conveying new quality to their quotidian work and lives. The "dissolution" of the public pensions system is neither conceivable nor desirable because the state, by virtue of its role, must assume the responsibility of ensuring minimum social solidarity between generations and among the diverse categories of the population.

The Ways to Combat Tax Evasion in Romania in Conditions of the World Economic Crisis

Ciurlău Loredana

„Constantin Brâncuși” University of Târgu-Jiu

lciurlau@yahoo.com

Abstract

Underground economy in Romania is particularly undeclared activities and less illegal activities. I circumvented the statements, those activities and would have to pay income taxes, but do not do it willingly.

Underground economy consists of all economic activities in an organized manner, with the overcoming of social norms, of economic laws, aiming to obtain income that can not be controlled by the state.

Key words: world economic crisis, tax evasion, underground economy, fiscal surveillance, tax law.

J.E.L. classification: G01

1. Introduction

Across the world, tax evasion is difficult to quantify. But there are economic methods that can be assessed. First of all, there is a distinction between tax evasion and tax avoidance through legal means. While the former is illegal, the second is perfectly legal. Tax evasion can be defined as the amount of payments made, but officially undeclared. All activities are included in the tax evasion tax evasion partial and total, both constituting the underground economy.

A first method for quantifying the economy is based on estimates of revenues and expenses related to the population. Obvious difficulty of this method is the fact that people have integrated into the economy's interest to conceal their activities. The information collected for purposes other than tax avoidance measure may be used.

The second method is to deduct the tax evasion of other economic variables. This can be done by measuring the overall economic activity, less the taxed activity, thereby achieving the economy. Tax evasion

in Romania is a significant part of the economy. This substantial part of the existing economy in our country is great because the conditions are conducive to defraud the tax authorities for this phenomenon have large growth over the official economy.

2. Characteristics of tax evasion in Romania

The causes and circumstances in which the phenomenon of tax evasion, have led to the definition of its general functions, determined - as a last resort - one variable: fiscal policy. In Romania, the emergence and manifestation of the phenomenon of tax evasion is even more dramatic as the Romanian society is not only a turning point in its existence, but also a sensitive economic times.

The phenomenon of tax evasion is subject to two factors:

➤ **endogenous** expression by the tax authorities and

➤ **exogenous** variables expressed through economic, social, cultural and psychological.

Cases that have facilitated tax evasion are:

■ conducting activities without legal authorization;

■ deliberate intent to circumvent or breach of the provisions of tax law, the intention of avoiding payment of taxes and contributions;

■ postponement or refusal of payment of tax obligations accurately determined;

■ incomplete or incorrect records management underlying the determination of costs, revenue and tax obligations;

■ full exploitation of inconsistencies or inconsistencies in tax laws or arbitrary interpretation of its provisions in respect of tax incentives;

■ ignorance of tax laws.

In Romania, tax evasion is manifested in the following forms:

- charging prices below cost for raw products delivered and duty calculation based on these prices;
- revenues are not accounted;
- the use of forged foreign bills;
- unreported sales;
- false deductions;
- registration errors intentional;
- requests for refunds undue.

Among the measures that can help fight tax evasion in Romania, noted:

■ unification of tax legislation and its better correlation with the overall legislative framework of the economy;

■ elimination of provisions in legislative acts that may encourage tax evasion and better correlation of tax incentives;

■ reorganizing the territorial structures of MPF device so as to eliminate duplication and overlap of activity of financial and fiscal control, in terms of fiscal surveillance, control and combating tax evasion;

■ setting an optimal ratio between wages and incentives for incentives fiscal system;

■ implementing a system that would provide the data necessary to identify, analyze and combat tax evasion phenomenon;

■ establishing a national system of permanent training of staff in the Ministry of Finance responsible for identifying and combating tax evasion.

Implementation of new legislation on countering tax evasion stage aims to redress the situation. These rules complete the legal framework of the current tax system and implement any specific action tools market economy, that tax penalties.

Tax evasion is as old and ubiquitous in society, how old is the presence and state tax laws. There is a psychology of taxpayers, boosted by the lack of tax education, plus the size of the tax burden, legislative and administrative deficiencies of tax administration, which causes and manifestations of tax evasion.

Tax evasion is a social phenomenon with financial implications, which is to circumvent the right of taxpayers to pay their respective tax liabilities, partially or wholly using legal loopholes or by means of ingenious

maneuvers in order to conceal taxable material. Field of manifestation of this phenomenon is as extensive as it is wide and varied scope of tax. Frequency of tax evasion is influenced by assessing their income.

Tax evasion is a social phenomenon with financial implications, which is to circumvent the right of taxpayers to pay their respective tax liabilities, partially or wholly using legal loopholes or by means of ingenious maneuvers in order to conceal taxable material. Field of manifestation of this phenomenon is as extensive as it is wide and varied scope of tax. Frequency of tax evasion is influenced by assessing their income.

The main types of tax evasion occurred in Romania, grouped according to activities by which it generates, are:

a. in the area of import, production and marketing of petroleum and petroleum products

b. the import, manufacture and marketing of beverage alcohol and alcohol, the main method used by businesses to avoid taxes on the transfer market has been trading companies by foreign nationals;

c. in the service industry and construction when fraud is the Romanian companies registered abroad or services rendered in the country, which then can not be quantified or identified.

In order to prevent, detect and timely handling of the underground economy, generating tax evasion factors, in addition to legislative measures financial and tax to be imposed, I think it should take into consideration the following:

Ⓢ realization and development of partnerships with entrepreneurs, through meetings and mutual briefings on the progress of the phenomenon of tax evasion in the area of responsibility;

Ⓢ development cooperation with state institutions with responsibilities in the prevention, detection and investigation of facts and factors generating tax evasion through the conclusion of protocols to be specified in the modalities of action, exchanging data and information;

Ⓢ approach on a modern basis, actions and special missions, that the effects to be expected, the investigation of complex cases;

Ⓢ improvement and harmonization of legislation specific fiscal and financial control bodies with E.U. regulations, so as to

achieve an increase in the responsiveness of the institution with operational situations in the various fields of activity;

② creation of a modern moral and professional conduct among staff with control, in conjunction with an appropriate salary, that, on this basis, to ensure confidence and respect of individuals and legal entities and state institutions to obtain a wider support as in an effort to prevent and punish fraud and tax evasion, including general factors;

③ development collaborative relationships with similar institutions abroad, in order to harmonize their standards with those imposed by the E.U.

European countries have begun drafting measures to support their economies and to strengthen public finances. These measures are different in form, purpose or budget impact, some countries chose to introduce substantial while others, for various reasons, have relied solely on economic stabilizers.

Most have used tax cuts while some have opted for measures to increase revenues due to lack of ability to have generous budgets, the amounts necessary to provide specific measures

3. Conclusion:

In Romania, the reasons for tax laws is a case of tax evasion, are represented by the various amendments to the legislation, issued regulations for certain correlation taxes, uncertainties and interpretations of the law leading to inconsistencies between the normative acts. To encourage the private sector, attracting foreign capital and the development and modernization of specific sectors of activity, many governments have provided tax incentives to investors.

Developing the underground economy can have very destructive effects, because the activities of the underground economy escapes taxation and reduces state revenues.

First in terms of tax evasion is the development of taxation legislation, to eliminate ambiguities leave room for interpretation that can be exploited by evaders. Secondly, the fight against corruption must be stepped up from among the factors Avenue law enforcement, both by their harsh punishment, and by improving methods of tracking the behavior and

fortunes accumulated by those officials. Finally, consideration should be given to reducing gradually as the budgetary possibilities, the level of certain categories of taxes which amount is very high in order to reduce the temptation taxpayers not to pay such taxes. One of the most commonly used anti-crisis measures is the direct support of the power consumption of households by income tax cuts; temporary reduction of value added;

States should consider the impact of the crisis and that measures will have on economies and end the crisis. Analysis but must be differentiated, especially as measures aimed at certain industries will have to prove their effectiveness, even if they were not and may not be consistent across Europe.

However, measures to stimulate consumption shows orientation rather than labor and capital investment. The effect of the crisis is felt best but the effect of international consensus on the taxation of foreign investment, honesty is the first priority issue for the entire business community. in this respect, the European Union directive on mutual assistance on information about the investment seems to enjoy priority.

Romania does not excel in fiscal measures compared to other European countries strong, especially due to inability to meet such financial measures. We are unfortunately in a time when, I believe, we only treat a chronic disease without hope of healing. But things have still kept under control and the EU membership hopeful, if not guarantee that we can overcome this crisis.

Abstract

The analysis of the evolution of scientific research on accountancy is extremely important as one can only judge the present phenomena that characterize a certain field on the basis of a solid historical background.

The aim of this paper is to offer an overview of the evolution of accountancy from the fifteenth century to the twentieth century, that is from the emergence of the various forms of writing and paper discovery to the use of logismography and, further on, the elaboration of balance sheet theories.

It also seeks to emphasize the way various schools of accounting thinking regarded accountancy at different moments in history.

The paper is divided into six different parts (except introduction and conclusions), each part corresponding to a certain period in accounting history.

Key words: accountancy, double-entry accounting, accounting theories, logismography, balance sheet.

J.E.L. classification: M40, M41.

1. Introduction

Accountancy is a scientific discipline within the system of economic sciences, which has its own object and research method. Analyzing the evolution of scientific research on accountancy is extremely important because: “If someone manifests the desire to become a master in a specific art, he or she must study its history. Without having a historical background, our knowledge is incomplete and the judgment of current phenomena is precarious and lacks maturity”

[1]. The arise and development of accountancy were determined by the practical needs of economic life [2].

At the beginning, “rudimentary bookkeeping” or “statistical accounting” manifested as a record of various goods, out of practical needs (cuts on animal bones, using pebbles, etc.), its development being closely linked to the development of human society and especially to the great discoveries of mankind.

A special moment in history was the emergence of the trade with goods and, subsequently, the emergence of the currency as a general equivalent, the emergence and development of the various forms of writing and that of figures. We must also emphasize paper discovery, which was firstly used by the Chinese [3].

The first accounting entries were made in ancient times by the means of the king of Babylon, Hammourabi, the initiator of the first commercial and social law code. The study of Hammourabi’s code led to the conclusion that Babylonian people knew the concept of active and passive and used documentary evidence to record commercial transactions.

Research has shown, without doubt, that the Egyptians, Greeks and Romans had accounting occupations, mostly for practical reasons.

The work of Leonardo Fibonacci is remarkable for the Middle Ages; for the first time, he proves how Arabic figures can be used, by drawing up an account using these figures.

2. The fifteenth century

The year 1494 marks a special moment in the history of accountancy. Luca Paciolo's work "Summa de arithmetica, geometria, proportioni et proportionalita" which, in Part I, Section II, Chapter XI presents the "Treaty of accounts", appears in Venice. The diagraph accounting system described by Paciolo led to the development of new theoretical constructions and accounting techniques [4].

3. The sixteenth century

During the sixteenth century, Italy, which had branches in many European countries (Germany, France, Netherlands, etc.) contributes greatly to the spread of the Venetian system of accounting.

On the other hand, the officials of the branches of different foreign commercial or banking houses located in Italian cities preach the new system to their countries. Some of them even become the authors of accounting works of art.

Thus, Matthaus Schwarz, who was bookkeeping for the Venice branch of the trade and banking company "Jacob Fugger", learns the new Italian accounting technique. In 1518, after becoming chief accountant of the Fuggers' company, he draws up an accounting manual - *Musterbuchhaltung*, in which he articulates the German factorial accounting system with elements that are specific for the Italian double entry.

After its establishment as a system, double entry accountancy becomes a subject in schools and copies of some textbooks circulate in manuscript and turn into occult sources of inspiration for various authors. Domenico Manzoni in Italy and Alvisé Casanova in Italy, Valentin Mennher de Kempton in Belgium, Claes Pietersz de Deventer and Leon Mellema in Holland, Passchier Goessens in Germany are not only authors of accounting papers published during the sixteenth century, but also accountancy teachers [5].

During the sixteenth century, the main authors of accounting works with contributions in the field are the following:

In Italy, Giovanni Antonio Tagliente publishes two papers in which he presents the mechanisms of single entry and double entry.

In 1539, appears the work „*Practica Arithmetica*”, in which the author Giralamo Cardano reserves a separate chapter for accounting matters. The paper is written in Latin, which was considered to be the scientific language of the era.

In 1540, Domenico Manzoni publishes an almost faithful copy of the work of Luca Paciolo.

The one who uses the "balance of entry" (opening balance sheet) account is the Benedictine monk Angelo Pietra. His merit also consists in the fact that he adapts commercial accounting techniques to the specific of non-profit institutions.

In Belgium, trade expansion led to the development of accounting techniques. The great authors of double-entry accounting works are localized in the Belgian city of Antwerp. Out of the most important ones we mention Valentin Mennher de Kempton.

In the Netherlands, the list of authors of accounting papers includes: Claes Pietersz de Deventer, Bartholomeus Cloot and Leon Mellema.

In Germany, the most important accounting work is produced during this century. The one who really introduces double-entry in Germany is Wolfgang Schweiker. At the end of the sixteenth century, exactly a century since the first double-entry accounting book was published, the work of Paschier Goessens, in which the accounts "Capital" and "Profit and loss" had identical functions with those of today, sees the light of the print.

Hugh Oldcastle is the one who introduces double entry bookkeeping in England, by translating Luca Paciolo's work into English.

In France, accounting books are printed relatively late. The first author of an accounting book is Pierre Savonne (also called Talon), who publishes in 1567 „*Instruction et maniere de tenir livres de raison et de comptes par parties doubles*”.

In Spain, Jean Ventallol publishes the work „*Practica Mercantivel*” in 1553.

4. The seventeenth century

Starting with the seventeenth century, the modern accounting era begins. In 1608, Simon Stevin's work appears in five volumes: "Wiscontige Gedachtenissen".

The well-known Italian authors for their accounting papers published during the seventeenth century are: Simon Grisogono, Giovanni Antonia Moschetti, Ludovico Flori, Giovanni Domenico Peri and Bastiano Venturi. The name of Giovanni Domenico Peri is linked to the first use of the term "azienda". The forms of the journal and the accounting ledger are different from the Venetian ones, being closer to the Tuscan models [5].

Bastiano Venturi offers the accounting study a new direction. Through accountancy, the Italian author intended to facilitate the achievement of maximum efficiency for each of the parties of the patrimony of azienda, by their administration with minimal expense.

He adopts the personalistic theory of accounts, laying the bases of the administrative doctrine two centuries before H. Fayol.

The particular aspects of his work made him the head of a school of accounting thought, the "Florentine school".

In the seventeenth century, Germany, which was also facing economic downturn, had a much poorer accounting literature quantitatively and qualitatively compared to the previous century.

During the seventeenth century, economic activity is increasingly moving towards North-East. Netherlands becomes the strongest financial power of Europe.

Representative for his writings in the field of accounting is Abraham de Graaf, who publishes, in 1688, in Amsterdam, the work "Instructie van het Italiaens Boeckhouden".

To establish correspondent accounts, Graaf uses two pairs of questions: "who receives" and "who gives" in the case of third-party accounts and "what do I receive" and "what do I give" in the case of value accounts.

The most well-known representatives of the seventeenth century in Great Britain are: Richard Dafforme, Abraham Liset and John Collins (author of "An Introduction to Merchants Accounts" - 1664).

In France, the seventeenth century creates favorable conditions for the development of accounting literature; one of the favoring factors was the "Order of trade" given by the finance minister of Louis the fourteenth, Jean Baptiste Colbert. Through this "order", orderly and "en-detail" bookkeeping is

regulated and the interest in accounting books is highlighted.

Another representative of the French school of accounting, in chronological order, is Claude Irson, who publishes in 1678 a paper which recommends the use of three journals: Cash Journal, Journal of purchases and Journal of sales. To end the period, he envisages the formulation of an article through which to activate the account "closing balance sheet" [5]. He was also the first to use the term "balance sheet" instead of "closing balance".

Mathieu de la Port is the author who gives accountancy the classic form that we know today. His best-known work is „La science des Negociants et des teneurs de livres”, published in Lyon and Paris.

During this century, the oldest accounting book is published in Sweden: „Instruction liber das itallienischen Buchhaltens” (1669), by author Merschidt Cyriacus.

5. The eighteenth century

The accounting literature of the eighteenth century undoubtedly puts France on the first position, both in terms of the volume of writings as well as the consistency of ideas presented, as a continuous combustion engine, which pushed accountancy from one decade to another. The French authors who made themselves conspicuous during the eighteenth century are: Samuel Ricard, Bertrand-Francoise Bareme and Edmond Degranges de Rancy.

The merits of these authors refer to the proposal to use several helping books, the advice on evaluating goods at their cost through inventory (Samuel Ricard) and the proposal to introduce double entry in the work of public finances [6].

The one who crystallized the accounting thinking in France for many decades was Edmond Degranges de Rancy, by publishing in 1795 the work „La tenue des livres rendue facile”.

Despite the decline of the Italian accounting movement in the eighteenth century, a few names and papers may be considered important. These include the work of Tommaso Domenico, Raffaello Secchioni and Pietro Paolo Scali. The name of Giuseppe Forni is linked to the use of mathematical methods for explaining the

relationship between accounts (using algebraic formulas).

Although during the eighteenth century more accounting papers were published in Great Britain than in other countries with more ancient traditions, they were mediocre.

During this century, Samuel Friedrick Helwigs and I.M. Stricker publish accounting papers written in German.

The school of "Austrian Lombardy" begins the scientific study of keeping public finance accounts. G.C. Heyne, T.G. Flügel, G. Brandt and M.I. Ressler produce accounting literature for the Austro-German environment.

In 1762, Puechenberg, chief accountant of the Imperial Accounting Chamber, established by Maria Theresa in 1760, publishes the work „Einleitung zu einem verbesserten Kameral-Rechnungsfusse”.

In the U.S., an accounting literature is developed starting with the eighteenth century; the main authors are W. Jackson and W.J. Alldrige, the later publishing in Philadelphia, in 1797, the work "The universal merchant in theory and practice".

6. The nineteenth century

In the nineteenth century, a lot of accounting books appear and this trend continues during the next century as well.

The representative of the Lombard school, the Italian Francesco Villa, is considered to be the promoter of scientific accounting in Italy.

During the nineteenth century, the representatives of the Tuscan school (Francesco Marchi and Giuseppe Cerboni) manifest themselves. Furthermore, Giuseppe Cerboni develops logismography as a modern expression of the personalistic theory of accounts, which assigns all accounts to people.

According to the concept of logismography, any administrative operation gives rise to debit and credit relations between natural or legal persons, capable of rights and obligations or which exert an action within the enterprise. To reveal these relations, each person must be opened an account. Therefore, accounts must be absolutely and exclusively personal. It is a legal and administrative personalistic theory [6].

By the method of accounting technique that Cerboni creates, the account of the owner and the account of the agency (agents and correspondents) are kept in permanent balance with the help of the logismographic journal.

The founder of the Venetian school is considered to be Fabio Besta, who creates a materialistic theory of accounts, based on the value of the account object [5].

His complete work, consisting of three volumes, appears between 1885 and 1889 under the title of "La Regioneria". Fabio Besta believes accounting is the science of economic control, classified among moral sciences.

Among the representatives of the French school of accounting of the nineteenth century, R.P. Coffy comes to the fore with his famous papers: „Tableau synoptique des principes generaux de la tenue des livres a parties doubles" (1833) and „La tenue des livres a parties doubles" (1834). In his papers, Coffy emphasizes accountancy's character of economic science.

At the end of the nineteenth century, the French school of accounting links this science to mathematics, seeking and establishing permanent relations between the various aspects that may explain the mechanism of accounts.

The French representatives of these theories are: E. Leautey and A. Guilbault, who publish, together or separately, papers that enjoy a wide reputation. Their best-known work with a positive impact in the field of accounting is „La science des comptes", published in 1889. It is followed by an equally well-received paper, „Principes generaux de comptabilité", published in 1895.

As representatives of the mathematical theory of accounting, the two authors believe that the account is a calculation whose purpose is to compare different sizes in order to establish a report that enables their quantitative or qualitative determination.

They are also the protagonists of the "dual personality theory", according to which a mental duality of the merchant's personality is produced. On the one hand, the merchant is regarded as a capitalist who brings funds and, on the other hand, as a guarantor or seller. The capitalist is represented by the account

"Capital" and the seller by all the "accounts of commercial values".

These accounts follow the classic rule: "The account that receives owes to the account that delivers". The receiving account is, therefore, debited and the delivering account is credited [6].

By publishing the work „L'Economologique (science comptable) et son histoire", L. Gomberg, states that accountancy can use mathematical methods; yet, he warns that there are differences between the two sciences.

"Economology" deals with budget principles, the evaluation and estimation of economic assets and operations, and the formulas by which inventory is made.

The author of another accounting theory, the so-called "positive" theory, is J. Dumarchey. He sees the essence of accounting into value and the account is regarded as a class of value units. In his view, accounting is a science that is part of the economic and social sciences and which gains individuality as a science of accounts [6].

7. The twentieth century

During the nineteenth and twentieth century, accounting papers are published also in the German space. The most prominent authors of those times are, among others, Johann Fr. Schar, Fr. Leitner and Manfred Berliner (author of the "enterprise theory").

This period is associated with the creation of the balance sheet theory; the promoter of this theory is W. Osbahr who publishes in 1918 the work „Die Bilanz von Standpunkt der Unternehmung". He is followed by Eugene Schnalenbach, Wald and Heplenstein (with the dynamic theory), H. Nicklisch, Frederich Lietner and Manfred Berliner (with the static balance sheet theory), Walter le Coutre (with the integral balance sheet theory), H. Sommerfeld (with the eudynamic theory), Wilhelm Rienger (with the nominalist balance sheet theory) and Erick Kosiol (with the pagatoric balance sheet theory).

Regarding the issues related to the nature of accountancy, German researchers are divided into two groups of thinking. A group headed by Schar, Berling and Oswald sees accountancy as a scientific independent

system. The second group is less concerned with the field of accounting theory. Having no intention of turning accountancy into a distinct science, they sometimes see accountancy more as a technical method of calculating values with broad applicability to the study of the enterprise.

The second half of the twentieth-century brings along studies and treatises in which leading economists write about national accountancy.

This is a time when national accounting principles and standards are spread by official documents.

The concrete shape of the national accountancy applied in each country at a certain moment is conditioned by the level achieved by global theoretical research and each country's individual experience in the field. The influence of the model that the country chooses to follow is not less important [4].

8. Conclusions

Appealing to the history of accountancy and thus of the accounting profession is necessary for explaining the contemporary structure of accountancy and accounting requirements.

Acquiring knowledge in the field of accountancy in various geographical areas has always been the concern of business partners, mainly for practical needs. Practice is thus the engine that grounded the development of the accounting processes and techniques; still, the merit of accounting theoreticians must not be neglected.

The combination between practical needs and the theoretical work of accounting authors eventually led to the development of the accounting science. Recording all economic operations has always been a goal, especially under the current conditions, when the effects of globalization are more and more obvious.

Accounting professionals are increasingly invited to respond to the challenges of practical life by implementing the accounting techniques and procedures in a regulated framework.

Abstract

The national context in which change and reforming government is synthesized in any government program, based on new principles, which includes the following objectives: Public administration reform, based on increasing local autonomy and the financial and economic; restructure the central and local government, aiming to achieve an effective organizational model of administrative structures, while drastically reducing public expenditure; reducing bureaucracy and streamlining public services.

The Prefecture aims to provide citizens, high-quality public services, in accordance with the needs, requirements and expectations, as well as those established by law. Thus, the institution will sustain a strong culture of quality, to ensure continuous improvement of services and to increase its customer satisfaction;

Key words: Prefecture, Management, ISO – QMS, Self-evaluation, Customer

J.E.L. classification – Publics Economics, Public Management,

1. Introduction

In the context of efficient use of financial resources, human and material in the public sector, service quality has recently become a fundamental goal for all institutions and public authorities. Thus, among the primary objectives of public management should fall and creating the perception that the provision of all administrative and public services must be made to the highest quality standards. In

order to improve the quality of activities and services provided to customers and to obtain ISO 9001:2008 quality certificates, Prefecture has set the objective of designing and implementing an effective quality management system. The process is ongoing: the institution conducting a diagnostic analysis, system design, human resources training and documentation development, implementation of quality system certification – ISO and final analysis.

2. The self-evaluation, way to increase the quality of public services

The self-evaluation is a tool for total quality management excellence model inspired by the European Foundation for Quality Management (EFQM) model and Speyer of the German University of Administrative Sciences. The self-evaluation is based on the premise that excellent results-oriented performance of key individuals, human resources and society are achieved through leadership, defining policy and strategy, leading employees and using partnerships, resources and processes. The self-evaluation to the organization of work from different angles simultaneously, to generate an overall analysis of organizational performance.

3. The analysis of organization and functioning of the Prefecture

According to the program of activities for ISO 9001 certification of the Institution of the Prefect, approved by Order of the Prefect, the working team constituted for this purpose has developed a comprehensive institutional analysis.

Also, a true and complete diagnostic analysis of the organization and operation cannot be developed without taking into account human vision. The self-evaluation was also used to produce diagnostic analysis.

To identify existing problems, there were two types of analysis:

1. **Problems Tree** (determine the causes and effects of the main problem)–view fig.2;
2. **SWOT** analysis (determine the internal weaknesses that can be improved and external negative aspects that could be turned into opportunities).

Problems Tree

The main problem identified is the poor quality of services provided by Prefecture. It is generated by two types of cases: cases dealing with the internal environment of the institution (and falling generally across government) and cases dealing with the external environment.

SWOT Analysis

Weaknesses of the internal environment are:

1. Insufficient motivation of human resources, mainly due to:
 - a. failure to use effective methods of motivation, such as initiatives to stimulate employees and promote good practices;
 - b. lack of full transparency in relation to assessment systems and promotion of staff;
 - c. lack of an objective and realistic set of criteria on which assessment systems, promotion and rewarding work (sometimes) non-recognition of professional merit by senior staff;
 - d. lack of strategic management elements of the institution (such as mission, vision, values, objectives), disseminated and promoted among staff so that the latter to set their own goals;
 - e. lack of training and staff awareness on quality;

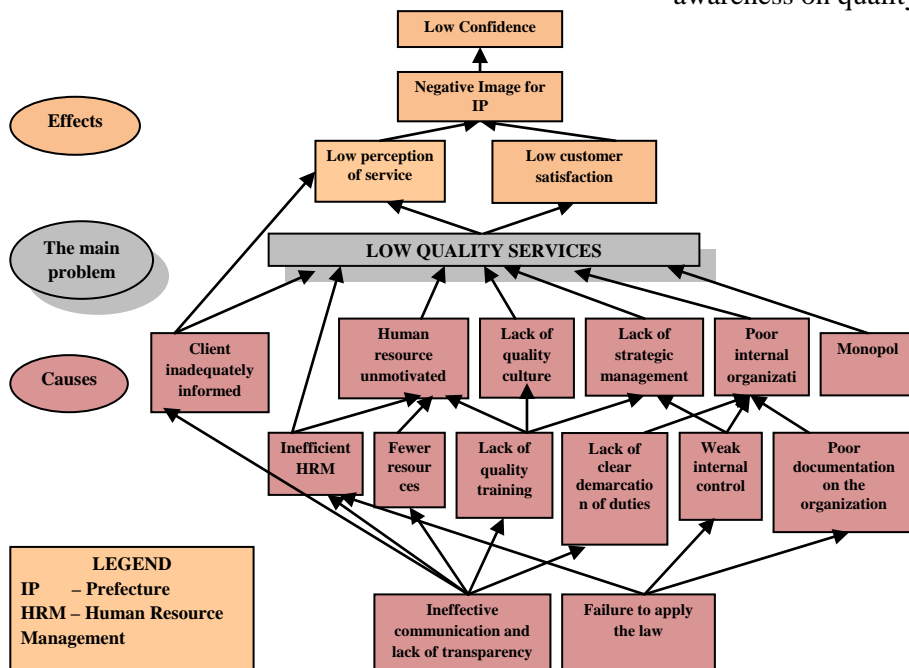

Fig. 1 Problems Tree

2. Material and financial resources are one of the causes of low quality service due to:

- a. Lack of a strong quality culture among employees, which could lead to increased quality of services by shifting attitudes and behavior towards clients and staff quality;
- b. Lack of effective communication within the institution, but also the external environment.

Communication between employees of the same department, interdepartmental and communication between management and the employees. Is essential for the smooth implementation of activities, and hence increase the quality of services provided. Internal mechanism of any organization cannot function optimally without the most important resource - human resource - always know what to do, when, how and especially why.

Regarding the *external environment*, have identified two major *Weaknesses aspects*:

1. Lack of competition in the provision of public services. Specifically, Prefecture has a monopoly on the services they provide, so that the beneficiary has a choice between several suppliers and, therefore, offers. Therefore, public administration in general and Prefecture, in particular, have a strong tendency not to consider his client's needs and requirements as a priority in its activities. Thus, customer expectations remain partially or totally unfulfilled.
2. Ignorance of the customers within the competence of the Institution of the Prefect. Sizing the area of responsibility leads directly to customer expectations in relation to sizing their institution. .

Regarding the *Strengths* identified by analysis, it is worth mentioning the following:

1. At the highest management level (prefect of the county) is directed by the client, open and oriented towards quality, sometimes only a declarative way;
2. Average age of employees is low, which favors the introduction of modern tools and techniques of service, commitment to the

introduction and implementation of strategic management elements, generating a pro-active, results - orientation of education;

3. High level of professionalism among human resources, due to the high proportion of employees with university and post-graduate studies;
4. The existence of internal procedures related to accounting activities, issuing passports and registration;
5. Creating a working group to design and implement quality management system (QMS), and a Working Group on the use and implementation of the self-evaluation as an instrument of modern institutional analysis.

The *Opportunity* to improve the quality of services provided The Prefecture is the possibility to apply for EU structural funds in the development of administrative capacity and opportunity to be included in a project – pilot.

Thus, it could create the framework for purchasing IT&C equipment and other resources necessary to increase training for human resources of the institution, and other activities targeted to the prefecture and its customers.

Also, the availability of ministry staff to support The Prefecture, including by organizing and conducting training seminars, is an opportunity in the real chances of the institution to provide quality public services.

On the other hand, have been identified as *major Threats*:

1. The political instability and
2. Continuous change of government legislation.

It is therefore essential that:

1. Positive aspects falling within the institution to be maintained, promoted and developed (improved);
2. Negative aspects to be reduced or even eliminated;
3. Opportunities to be analyzed and used to achieve the goal of improving the quality of services provided;
4. Threats to be constantly reviewed and monitored so that, where possible, to remove their potential negative effect on the organization and functioning of the institution.

4. The Strategy of Quality in Prefecture

For the strategic project were defined first defining elements of any strategy: purpose, vision, mission, values. Distinguish a set of values that emphasize that simply want to replace the concept of citizen, with the customer and the project will pursue all activities centered on the customer.

Prefecture values County operates the principles on which total quality management.

But who are the beneficiaries of all these goals?

1. *Customer* – by satisfying the requirements and needs for services;
2. *Institution partners* – ensuring confidence in the institution and an improved quality of services provided;
3. *Employees* – by increasing motivation, involvement and their attachment to the institution;
4. *Prefecture itself* – by reducing the costs of non-quality, improve image, streamline activities, increase confidence in the institution and its management, decrease repetitive errors, creating a climate conducive to professional development of employees.

The next step consists of *defining the strategic objectives*:

1. Increase customer satisfaction;
2. To improve the organization and functioning;
3. Improving the image.

And then the operational objectives:

Operational objectives for the no. 1 strategic goal

1. Improving customer relationship;
2. Increasing awareness of the needs, requirements and expectations;
3. Increase customer awareness on areas of responsibility.

Operational objectives for the no. 2 strategic goal

1. Ensuring a stable and effective organizational framework;
2. Human resource development;
3. Raising awareness and motivation of employees on quality management;
4. Improving internal communication within;

5. Increased transparency of the budget for;
6. Attracting financial assistance grants provided by the EU;
7. Improving external communication;
8. Continuous improvement of service provided;
9. Strengthening the conduct surveillance activities in the functional structures.

Operational objectives for the no. 3 strategic goal

1. Increased awareness of efforts to improve the quality of services provided;
2. Improving the quality of the interface;
3. Increased involvement of civil society in action.

Upon completion of defining the objectives to be reached, the manager may proceed with the project implementation progress in time and space which represent it in a table attached. The strategy is mandatory for all staff, from the date of its adoption by order of the prefect.

The next step is a careful monitoring and ongoing assessment of activities to implement the strategy.

Monitoring will be an ongoing process and is based on the evaluation process also provides the necessary adjustment of both the strategy itself and its implementation will be undertaken by a working group established by order of the prefect. It will develop a monitoring report each in its own operational procedures.

The evaluation will be conducted by the same working group on monitoring reports and other tools such as questionnaires, interviews and reports, internal and external audit etc. Following each assessment will produce a report that will be presented to the leadership of the institution to identify and implement necessary corrections and corrective actions. Evaluation will be based on operational indicators set by the procedure above.

For a correct evaluation of great importance is the impact and results. The impact of the main results expected from implementing the strategy is:

- Improve the efficiency of the institution, by applying the elements of strategic management and building and maintaining a quality culture;

- Reduce / reduce non-quality costs, by reducing / eliminating errors and streamlining the work of the institution;
- Increased quality of services provided;
- Full involvement of the management team and executive staff in achieving quality, due to increased awareness and training on quality and quality management;
- Motivated human resources and attached to the institution, due to the awareness of their roles, missions and objectives embedded in the institution of the Prefect;
- Customers with a high degree of knowledge regarding areas of competence of the Institution of the Prefect;
- Meet the needs, requirements and expectations;
- Improved image and increased confidence

Failure is felt deeply in human beings, especially when the failure of an organization reflects more on the manager's organization. All failures "break the head" manager because the manager responsible is the only feature that cannot be delegated. As a manager, if you empower a person to perform a task and it is a failure, then the manager responsible is not known because they choose to or because the employee had not delegated that task. For these reasons, every manager must be endowed with power to take equally, both success and failure. A manager is not only strong when no failures - this is virtually impossible, especially when failure is experienced and taken quickly remedied, corrected and restarted - the end result is success.

Failure if the self-evaluation strategy and implementation of quality management system QMS – ISO in Prefecture, there is a certain failure, as the institution is at the limit of its credibility before the people and even deadlock failure to achieve its objectives.

Therefore, the prefect, failure in this case will produce a great mental pressure, which correlated with all the obstacles and unfavorable factors, may lead to a catastrophe.

After comparing the two situations should be deciding on the optimal deployment option. Are raised, in case of failure and non negative actions - actions and then, for all these solutions are correct. Finally, go to its implementation - called.

5. Conclusions

Organizational assessment questionnaire is the beginning of the institution's most important resource: human resource. Among the 60's questionnaires collected, there are a significant number of questionnaires were left blank on some questions or where undue negative aspects were reported. In this way, it created the foundations for designing an effective management system for ensuring and maintaining a high quality internal activities and services provided to citizens seeking. The ISO – QMS rules requirements for the management system of an organization that seeks to demonstrate the ability to consistently provide a product / service according to customers' requirements and legal requirements, to increase customer satisfaction through effective application of the system, including continuous improvement it.

To assess the internal Prefecture activity, resulting in employee responses were considered:

Structure - Most of the staff considers that the organizational structure of the IP needs to be improved, indicating that there are several shortcomings.

Employee - Although the activities they carry out the job description and corresponding to the ROF, employees have also identified some weaknesses regarding the overload of activities and implementation activities for which some were not specialized.

Rating - Although for some staff assessment is done fairly and transparently, most employees are identified and some negative aspects of the system of evaluation and transparency of the decision in their evaluation.

Training - Although some staff training for human resources is done in a transparent manner and there is discontent in this regard, the present system for most employees about the negative aspects of training programs that are not known to staff;

Motivation - The motivation system, employees have identified the following negative aspects especially relating to improper financial motivation.

Communication - The communication within and between services, employees have identified many negative aspects denouncing

even in some cases blocking communication, which can be corrected by implementing a communication strategy for internal and external to the institution.

Resources - Most employees have difficulties in carrying out his duties, due to insufficient material resources, especially IT equipment. There are claims including personal attitude of rejection, when seeking the resources necessary to fulfill duties.

Objectives and activities - For most of the staff, the goals that the institution should embrace and how to achieve them are related to continuous improvement, their motivation, ineffective communication and lack of stability framework.

By applying TQM in the public sector get many benefits including:

- 1.a flexible management system designed to allow continual improvement of quality services;
- 2.creating a corps of civil servants as motivated in their activity;
- 3.continuous improvement of customer relations;
- 4.process improvement in all categories of resource management in public institutions;
- 5.a system of continuous training of employees;
- 6.simplify management processes and execution of quality system procedures clearly defined and structured;
- 7.timely detection and correction information system deficiencies.

With these objectives, we wanted to win and maintain public confidence and all current and potential partners, and at the same time ensuring that service quality is improving and it will be an ongoing process.

But keeping close to our customers requirements, we provide quality public services in public institutions.

A Hayekian Economic Model of Thinking

Coca Veronica

"Alexandru Ioan Cuza" University of Iași

coca_veronica@yahoo.com

Abstract

The aim of this paper is to demonstrate that the economical model of thinking developed by Hayek can be verified through the game theory and theory of network. The model of Hayek involves the individual freedom as implicit condition for spontaneous order and economic activity.

We have verified the hypothesis: The sum of whole individuals' utility is greater than the individual's utility. The analyze is a theoretical one and like instruments we use the game theory and the network theory. The result show that individual wellbeing leads to the welfare society.

Key words: methodological individualism, utility, spontaneous order, network effect.

J.E.L. classification: B31, B53, D64, D82

1. Introduction

The Austrian economist, Hayek didn't become an advocate of government intervention like the majority post-war economists. He thought that centralized planning isn't compatible with market economy, individual freedom and rule of law. He remains a market supporter. [5] For him, like for Mises also, economic theory is a qualitative one and not quantitative.[13]

Assumption: Individual well-being leads to a welfare society and not the welfare society involve the individual wellbeing.

$\sum_{i=1}^n x_i > \max(x_1) + \max(x_2) + \dots + \max(x_i)$,

Where $\sum_{i=1}^n x_i$ represent the individuals of the society

$\max(x_i)$ represent the utility of the individual "i" which is endogenous, subjective and implicit (we cannot measure the utility in practice like in the neoclassical theory)

The implicit conditions for this equation:

- Individual freedom
- The "rule of law"
- The spontaneous order
- The methodological individualism

If in the Classical Economics, starting with Adam Smith, the economists proved that the gains come from free trade, in our assumption, the gains come from joint commitment and we want to demonstrate that just the individual following his own interest will maximize the group/society utility.

In this paper we use the theory of Hayek, especially the theory of knowledge, the theory of methodological individualism, spontaneous order and then we made the correlation with the game theory and the theory of positive network effects.

2. Methodological individualism

Individual utility cannot be measured cardinally because the position of different individuals are fundamentally non-comparable; even if were possible in principle (e.g. neoclassical theory) to compare them (ranking different individuals utility), there would be no way to do so in the real world.

Austrians' concept of methodological individualism (especially Hayek), considers individual preferences as given (endogenous, subjective preferences)[7].

$X_i \longrightarrow \max(X_i)$, where $\max(x_i) = v$;

"v" is the max utility of the individual "i" (which is endogenous, and cannot be measured; just individual "i" knows what is the best for him and we cannot find the elements to constitute an equation to provide the result of an individual utility). Preferences differ among different individuals; these are internal alternative situations and emerge out from a process of cultural evolution. Because individuals possess only limited information and are

subject to limited information processing capacity, they are "local utility optimizers"

To solve our equation, we have to find the way individual preferences are represented, then the possibility of interpersonal exchange or comparison and finally the aggregation rule.

We live in a world with asymmetric information. In any contract or transaction, there are possibilities of moral hazard or adverse selection, so nobody can have all the information necessary to take the right decision. The same demonstrate Hayek and Mises the impossibility of planning. The information is dispersed and nobody can have all the details to make a plan for whole economy. The good result is achieved just through individual action. The individual has the specific information (tacit information) for a specific action. The economic development results from individual action through trial and error.

Individual is selfish in market behavior and in the same time the parties in the market interaction aim to help themselves by satisfying the desire of others like the father of modern economy exemplifies: "It is not from the benevolence of the butcher, the brewer, or the baker, that we expect our dinner, but from the regard to their own interest. We address ourselves, not to their humanity, but to their self-love, and never talk to them of our necessities but of their advantages..." or "...whoever offers to another a bargain of any kind, proposes to do this: Give me that which I want, and you shall have this which you want...and it is in this manner that we obtain from one another the far greater part of those good offices which we stand in need of." [16].

3. Spontaneous order

In market process, actions are coordinated without a central, designing authority that drives and anticipates the result of coordination. Actions of individuals are being coordinated ex-post by their pursuits of own ends, utilizing the subjective knowledge.

The traditional view on general equilibrium is that there is a perfect market, where any event is known by all the market participants, but Hayek deny this theory saying that to understand the equilibrium (more exactly the tendency to equilibrium)

we have to analyze the way of people get the information relate to the event. Equilibrium, the tendency to equilibrium represents the result of individuals' coordination plans.

The theory of Hayek says that sensorial perceptions become personal instincts, which through individual adaptation and dispersed knowledge (and respecting traditions, common rules) lead to a free contractual collaboration. This contractual collaboration means that spontaneous order which involve evolution and development.

"Most of the knowledge on which we rely in the pursuit of our ends is the unintended by-product of others exploring the world in different direction from those we pursue ourselves because they are impelled by different aims; it would never become available to us if only those ends were persuade which we regarded as desirable"[12]. The explanation is that signals of the price system on competitive markets should influence the decision and not vice versa (the central decision should influence the price). Prices are good signals for market participations. Through the prices, the market participations receive the information about opportunity costs, scarcities resources, about demand, supply, about risks and changes. The price mechanism leads to an efficient allocation.

A market is a cybernetic system and every cybernetic system operates by feedback mechanism. [15]

Each economy is an order and consists of orders. The citizens are members (elements) of society. The individuals work together in order to satisfy individual needs. Own plans are based on expectation concerning the behavior of other. To advocate our affirmation we can use the game theory, especially the Nash-equilibrium in prisoners' dilemma.

Fig.1 Pay-off matrix of the normal form Prisoner's Dilemma game

	cooperate	defect
cooperate	3; 3	0; 5
defect	5; 0	1; 1

Source: A. Rogers, R. K. Dash, S. D. Ramchurn, P. Vytelingum and N. R. Jennings (2007) *Coordinating team players within a noisy iterated Prisoner's Dilemma tournament*, p. 245.

As we can see, the best outcome is a cooperating strategy (3; 3). This theory demonstrates that a good result can be achieved just through a spontaneous order (nobody knows what the other will say). The same is in the market: just through spontaneous action of the individual it tends to the equilibrium. Spontaneous orders exist as adaptations to specific local circumstances under general rules of conduct. These rules of conduct do not have to be explicitly known by all individuals. As Adam Ferguson says, spontaneous orders are the result of human actions, but not a human design. The individual elements of a spontaneous order act in accordance with their own objectives. Spontaneous orders use the locally existing knowledge and can be of high complexity. Any attempt to "improve" a spontaneous order by direct intervention is "pretence of knowledge" [10]. The state is a necessary, but no means a sufficient condition for economic growth. [2]

Important is "the rule of law". This concept is like the invisible hand of Adam Smith or the institutions from the New Institutional Economy.

Individuals are selfish "utility maximizers" that are only concerned with their own benefit, but altruistic behavior results from "arguments in the individuals" utility function. Cooperative behavior in a world with repeated social interaction is generally the best interest of individuals.

The model of rational agent, homo oeconomicus like in the neoclassical theory is just a theoretical model, which cannot be funded in reality. In a society, the individual act, produce, sell, buy, exchange. All of these means transactions and each transaction suppose at least two participants. In a transaction, there is no zero result; each participant has his own interest, but the result is not zero or negative. Each agent supposes to gain something from joint commitment. The best example for this case is the theory of positive network effect.

Viewing the economy as a network is different from what represent the neoclassical model. In the neoclassical model it is assumed that anonymous and autonomous individuals take decisions independently and interact only through the price system which they cannot influence at all. This is possible just in a market with perfect competition. In

reality, agents have only minimal market power and they will anticipate the consequences of their actions and anticipate the actions of others. This is what we want to explain through the game theory. This explanation was not sufficient, because we have to assume that the behavior is fully optimizing considering all possible actions and, in the same time, the actions of others. Another limit of game theory is that it doesn't explain the problem of coordination of activities.

The social network is a set of nodes or actors which are connected by a set of social relationships, ties, or a specified type of ties.

The aggregate behavior of an economy cannot be investigated in terms of the behavior of isolated individuals, as it is usually done in standard economic theory. Firms interact only with a few other firms, out of all firms present in the economy. There are different ways in which firms interact, and they may learn over time to adapt their interactions. We may view the economy as an evolving network.

Network effects arise when the utility of an object depends on how many other individuals or organizations use this object. If I am the only person who have a mobile phone, his utility for me is zero, but as soon as the number of people possessing a mobile phone increase, the utility of my mobile increase also. The more people have a mobile, the network effect increase and in the same time, my utility increase and the whole group's utility increase.

The same is in our relation

$$\sum_{i=1}^n x_i > \max(x_1) + \max(x_2) + \dots +$$

$\max(x_i)$, the utility of the group/society is greater than the individual utility.

The evolution of the network is dependent on the agents' experience from using the links (respectively contacts) available to them. Individuals learn and adapt their behavior and this in turn leads to an evolution of the network structure.

Two Germans economists proved in a study that there is a positive influence on people who are more connected, belong to different networks and their economical behavior. [14]

4. Conclusion and limits

We demonstrated that the economical model of thinking developed by Hayek can be verified through the game theory and theory of network. We used the social network theory because to achieve the equilibrium, the individuals should interact each other. It doesn't exist an atomistic individual, a homo economicus in reality, just in the neoclassical theory. The gains come from joint commitment and just the individual following his own interest will maximize the group/society utility. The tendency to equilibrium represents the result of individuals' coordination plans. These individuals' plans represent the spontaneous order. Market is like a network and this system operates by feedback mechanism, that's the explanation that what is good for an individual cannot be bad for the society and not vice versa. Because individuals are dealing with bounded rationality and asymmetric information we have to take into consideration the other elements that cannot be measured or counted (like risk). These will be the subject for further studies in this field.

Can SMEs Promote Sustainable Development?

Codreanu Carmen Mariana

„Petre Andrei” University of Iasi, Faculty of Economics
codrcarmen@yahoo.com

Abstract

The main aims of this paper were to evaluate, debate and disseminate SMEs initiatives in the area of sustainable development, to identify further dissemination strategies and options for SMEs and to identify information needs of SMEs.

Small and medium-sized enterprises cover 99.8% of all businesses and account for around two-thirds of employment in the EU. It is now generally accepted that these enterprises are key to growth and employment generation.

Well-managed SMEs are a source of employment opportunities and wealth creation. They can contribute to social stability and generate tax revenues.

SMEs can constitute an important source of local supply and service provision to larger corporations. They usually have extensive local knowledge of resources, supply patterns and purchasing trends.

Sustainable Development pursues and tries to find a stable theoretical framework for making decisions in any situation where such a report can be found man-environment, be it environmental, economic or social.

Key words: SME, wealth creation, social stability, Sustainable Development.

J.E.L. classification: F43

1. Introduction

Small and medium-sized enterprises play a key role in implementing the policies on sustainable development.

SMEs represent an important source of innovation. They tend to occupy specialized market “niches” and follow competitive strategies that set them apart from other companies. This might include re-engineering products or services to meet

market demands, exploring innovative distribution or sales techniques, or developing new and untapped markets.

Since the mid-1980s the environment, and subsequently sustainable development, has been a pivotal element of many SMEs.

SMEs research identified mechanisms to facilitate sustainable development in areas such as economic incentives, product design, environmental management, and training and education.

2. Promoting SMEs for Sustainable Development

SMEs often have a vested interest in community development. Being local, they draw upon the community for their workforce and rely on it to do business. For the communities, they provide goods and services tailored to local needs and at costs affordable to local people.

They are an important source of as women and young people, who usually make up the greatest proportion of the unemployed in emerging economies.

The objectives of the SME sectors are[1]:

- the agriculture and forestry: partnering with local farmers to develop new, sustainable timber plantations, forward payments to corn farmers to improve cash-flow and enable purchasing of supplies. SMEs should pursue reforms with a view to eliminating trade distorting subsidies, removing barriers to trade and reducing the overall level of public financial support for agriculture. This should be done in a coherent manner, without compromising the competitive position of the European food industry.

- the industrial sector: enterprise center to build capacity and create employment among local companies, building capacity to meet the company’s engineering and construction needs, investing in small construction stores by providing capital for new storefronts, computers, inventory-tracking software, and

management skills, Integrating local SMEs into its supply chain, training local youths to become masons and secure employment in the building industry, capacity building for SMEs to assist them to become self-reliant viable suppliers.

- the services sector: promoting local entrepreneurs in its paper collection & recycling program, providing equipment to assist local entrepreneurs to become distributors, employing women entrepreneurs to distribute health and hygiene products locally,
- the finance sector: providing microfinance to entrepreneurs. Improved coherence between trade policy/analysis and EU structural funding could contribute to strengthening regions or industrial sectors that need to anticipate or adapt to global competition. EU programmes that foster international technological and business cooperation with trade partners should be made more cost-effective and user friendly particularly for SMEs. EU development assistance should not only focus on export led growth but should also improve internal governance and include developing open and strengthened markets in developing countries.

To contribute on sustainable development, the enterprise has to:

- conducting to the development of economic support and to a good quality of life in the communities who function on the local, national, regional and world's plan.
- looking for a constant reform of the benchmark, the innovative capacity and the economic viability on the long term
- conducting for the reserves' preservation – naturals, materials and renewables – that plays an important role in the economic increment.
- anticipating and managing the risks.
- participating for the searching, learning and creating of the social process, which is the sustainable development, urging all the actors to take their responsibilities and favouring the participation of the minorities at the economic prosperity.

“While SMEs are critical to a country's long-term development, sustainable access to finance and inclusive business design are fundamental to ensuring long-term and

equitable poverty reduction and business profitability.”[1]

SMEs can play a much bigger role in developing national economies, alleviating poverty, participating in the global economy and partnering with larger corporations. They do, however, need to be promoted. Such support requires commitments by and between governments, business and civil society.

SMEs require a favorable institutional framework. Most are overlooked by policy-makers and legislators, who tend to target larger corporations. SMEs often miss out on tax incentives or business subsidies. They suffer more than big companies from the large burden and cost of bureaucracy, as few SMEs possess the necessary financial or human resources to deal with this [2].

SMEs support for sustainable development can take many forms and operate at many different levels:

- national dissemination/support programmes
- national funding programmes
- local/regional eco-efficiency clubs and networks
- regional support centers
- business eco-parks;
- supply chain initiatives.

While there has been a large increase in the number of initiatives targeting SMEs, support provision has not always been correctly tailored to the needs of SMEs.

Feedback suggests that SMEs that need support are often bewildered by the variety of initiatives potentially available. In some EU regions there are too many initiatives with little or no coordination between support organizations. Support schemes are often found to be:

- too abstract/impractical;
- too general (insufficiently tailored for particular sectors/industries);
- too passive (e.g. purely providing self-help materials);
- superficial or lacking in quality;
- too expensive, time-consuming or inflexible;
- poorly targeted or promoted.

There has also perhaps been an overemphasis on environmental management systems and certification (which do not guarantee significant improvements) at the expense of eco-efficiency, eco-design, integrated approaches (e.g. including

environment, health, safety and quality) and fundamentally more sustainable manufacturing (e.g. based on renewable resources).

There has also been too little integration within 'mainstream' education, training and support, for example covering engineering or clerical activities.[4]

Regional partnerships should therefore involve some or all of the following: local authorities and regulators, chambers of commerce/business support bodies, key industry (employer) bodies, trade unions (to inform/motivate employees), real sector/subject experts (e.g. consultants, university/college staff) plus support staff (e.g. graduates). Funding organizations can be particularly influential, offering financial support (e.g. for start up companies) but only subject to certain conditions being met.

Supply chains (through large, powerful companies), can be used to apply pressure to suppliers/customers and provide training and support (mentoring). Finally SMEs should be encouraged to form/join self-help networks, for example environment business, eco-efficiency and joint-EMS implementation clubs.

To encourage SMEs to join the formal sector, governments need to provide tax incentives for SMEs and subsidies similar to those available to large corporations or micro entrepreneurs and to make provisions for start-up funds for SMEs.

The many large corporations that source their supplies from developing countries require reliable suppliers.

Large corporations can help SMEs become more viable business partners by providing training in basic skills such as management, bookkeeping, business planning, marketing, distribution, and quality control. They can assist through technology transfers, direct investment in infrastructure, and the sharing of knowledge. This makes SMEs more competitive and facilitates access to credit.

All of this can benefit the large corporations by creating more effective and inclusive supply chains.

"Business is the most important engine of economic change. It brings employment, goods, revenues, knowledge and skills development. (...) We must also recognize that the most important role is probably not that played by the multinationals, but by the small and medium enterprise sector, the SMEs. We as global companies can provide the catalyst to partner with SMEs to mutual benefit.

We can access their local expertise and markets; they can access our technologies and business skills for local momentum." [5]

Relationship between University and Entrepreneurial Capacity of Students

Codreanu Carmen Mariana
Coștuleanu Carmen Luiza
„Petre Andrei” University of Iasi, Faculty of Economics
codrcarmen@yahoo.com
ccostuleanu@yahoo.com

Abstract

Paper analyzes the role of university in improving entrepreneurial capacity of students. This research aims to assess the university's action, its system of values and way of reporting on the outside and assimilation into work on stimulating and supporting entrepreneurship students. Preparing students concerns, especially, their creativity in thinking and action, skills and capacities to innovate, invent and to use the intellectual resources fully. Their activities and courses will be designed to develop a strategic thinking, independence, creativity, preparation for teamwork and required skills to solve problems. Improving students' training can be done by organizing various cultural events like open amphitheatres, workshops, studio groups, or conferences for special guests or for public, students' scientific circles, and practical guidance in production activity. This study makes an original contribution to knowledge of the entrepreneurial spirit of our students.

Key words: role of university, entrepreneurship, creativity.

J.E.L. classification: I21

1. Introduction

As a result of continuous adaptation of the educational offer, students must be constantly aware of national and international business and the university must identify and support those young people with high potential business ideas and which is strong manifested the entrepreneur spirit. The educational offer must adapt and develop in students the vital skills and attitudes appropriate to a highly competitive

environment, the entrepreneurial spirit, identifying opportunities and taking risks, accepting change as a way of life[1].

A program specifically geared towards this aspect include the promotion and expansion of an entrepreneurial culture and spirit of professional success through their own business, consistent and rapid transfer of university research results into economic activities by establishing a centre of technological transfer within the university, providing advice.

To establish their own business, entrepreneurs need a good planning, organization, accounting, management and marketing - areas of competence of higher economic education. Specialists of faculties of economics can support entrepreneurship training to graduates in other fields [2].

Research tool of survey is a questionnaire consisting of 29 questions, developed in order to focus the positive and negative factors influencing the initiation of an entrepreneurial career.

Sample consists of 74 students from the Faculty of Economics, University "Petre Andrei" from Iasi, aged between 19 and 35. Method of selection of students was random. Interviews were conducted face to face with those students in the university.

2. Improving student preparation

Preparing students concerns, especially, their creativity in thinking and action, skills and capacities to innovate, invent and to use the intellectual resources fully. Their activities and courses will be designed to develop a strategic thinking, independence, creativity, preparation for teamwork and required skills to solve problems. Their activities and courses will be designed to develop a strategic thinking, independence,

creativity, preparation for teamwork and required skills to solve problems. Improving students' training can be done by organizing various cultural events like open amphitheatres, workshops, studio groups, or conferences for special guests or for public, students' scientific circles, and practical guidance in production activity (figure 1).

Figure 1 – Improving student preparation

55.56% of the students towards either employment would like to improve their academic preparation through internships in companies, 14.14% want to attend seminars, 21.21% to be part of study groups, and 9,09% to participate in national and international conferences. Of the students surveyed in employment without interest, a percentage of 1.01% will make a business practice, 2.02% to follow in college seminars, 1.01% want to be part of the study groups.

Romania has a good and developed university education system with outstanding programs in all fields of study. At the

university level (undergraduate level) there are excellent programs for traditional disciplines, and for areas with direct professional reference. At postgraduate level (graduate level), students often have the opportunity to work with some of the brightest minds in the field. Romania's education system has to offer something for everyone. Some colleges and universities emphasize broad educational principles; some emphasize the practice, other professional skills training, while others specialize in technical fields, arts and social sciences [3]. As a result, if you are looking for an institution where you can study a particular area, you will be able to find high-level institutions and programs (figure 2).

Figure 2 – Expectation from University

Following university studies, students wishing to receive appropriate training during the years of study (63.27% of the total 98 points), others want contact with the labour market (26.53%), and with a rate of 9.18% of points some students require more attention on practical activities.

Improving university training can be achieved by developing practical skills by carrying out internships in investment in specialized institutions in the country with a well-organized professionally by acquiring new knowledge in cutting edge equipment

and technologies in order to adapt information to specific conditions in the country and offering new ways for specific training by providing new employment opportunities in line with the interest expressed by various institutions, by developing long-term international partnerships [4] (figure 3).

Figure 3 – Expectation of vocational training

The best activity used for improving the academic preparation of students was seen as a stage in the company (54.90%), followed by study groups (21.57%), seminars (14.71%) and conference (8.82%).

A percentage of 68.92% of surveyed students considered that university stimulates entrepreneurial capacity, while 31.08% of students are not pleased with university's way to stimulate the entrepreneurial capacity (figure 4).

Respondent students felt that university can stimulate entrepreneurial capacity as follows:

- doing internships in companies (44.44%),
- introducing new courses on entrepreneurship (29.63%),
- paying more attention to the needs of students (11.11%),
- by changing old ideas with new ones, through conferences, new types of businesses, creating study groups (3.70%) (figure 5).

Figure 4 – The University stimulate the entrepreneurial

Figure 5 – What has to do the University for stimulating the entrepreneurial?

University helps students acquire self-confidence (33.54%), education (21.28%), innovative ideas (18.09%), and updated information (15.60%), to know the experience of specialists (13.83%) and relations with the outside (12.06%). Among those responding were also some who voted negative, meaning that the university does not help students to have relations with the outside (24.84%), share the experience of specialists (21.74%), to have access to updated information (18, 63%), to implement new ideas (14.29%), have confidence (12.42%), to acquire education (8.07%) (figure 6).

Figure 6 - Aid for university students to acquire certain factors

Among students who have experienced the lifestyle of an entrepreneur and liked it, a percentage of 26.03% believe that entrepreneur is a person who has prospects of gain, 19.18% a person at risk and the same percentage (19, 18%) believe that the opportunist is being enterprising.

Students who do not know the lifestyle of the entrepreneur, but they are curious to know about it, believes that entrepreneur can be a person who has prospects of winning (17.81%), at risk (6.85%) and a person who takes advantage occasionally (1.37%).

Students who know the lifestyle of an entrepreneur, but do not like it, thought that the rate of 4.11% can be the entrepreneur who has prospects of success and the same percentage of 1.37% may be a business person assume risks and is opportunistic.

Respondents who did not know the lifestyle of the entrepreneur and do not want to learn about it, believes that entrepreneur can be a person who takes risks and prospects of gain (1.37%) (figure 7).

Figure 7 - The relationship between entrepreneur's characteristics and student's attraction to this

In conclusion it is clear that students consider university as a "job training" which should be based on practical activities. Students ask the university to create a bridge to employment for the purposes of pre-professional insertion. The application is clear and consistent and is in favour of internships in companies [5].

It is therefore the university able to encourage students to become entrepreneurs?

Abstract

Basically, the smooth running of any organization is provided by decisions that are taken in time, decisions that are correct as long as based on data and information on which to base those decisions.

Data warehouses are the product of advanced technology and economic environment. On the one hand, the economic environment is increasingly competitive, global and complex and requires information developed for supporting The strategic decisions and on the other hand, developments in information technology provides solutions for efficient management of large volumes of data integrated.

Most industry specialists believe that the data warehouse (data marts) and OLAP tools provide the necessary support to transform large volumes of data that companies working in information useful to decision makers.

Key words: Decision Support, data warehousing, OLAP, decision support systems, data analysis

J.E.L. classification: D89

1. Introduction

Increased competitiveness, frequent changes of business environment organizations have to adapt to all economic sectors subject to economic organizations to perform complex analysis on the data they hold in order to support decision making. These analytics solutions are possible by using information available to them analysts, analysis performed on data that are stored in operational systems, including databases, the organization that represents a real gold mine

of information that should undergo the process operation.

Mankind is engaged in a historical process of transition to a new society and a new economic system. Train historical progress and the future will bring radical changes in the substance of economics, reflected with great speed on training specialists in economy and in people's thinking [3].

The ability of organizations to adapt to the future economy depends on developing a new type of management focused on creation of scientific knowledge and values. Thus, knowledge-based organizations are collective actors intelligent information society and have a role in its assertion that the knowledge society, belonging to contemporary reality.

Currently, due to progress recorded information technology and telecommunications, access to data and information is more easily achieved, and so the question is to know more and more, and know how to use the maximum information that you have to a time.

Existing organization to learn and accept to survive in a global environment and this information must meet the following requirements: flexibility, openness, openness to integration and globalization.

To provide good leadership to make the best timely decisions about the good of his organization, every manager should have access to necessary information in a timely manner, information to be correct at the time of application and this aspect of management may be provided by new information technologies.

2. Data warehouses

Leadership involves taking an organization from the management team of a set of decisions on current activity, forecasting, investment, etc.. In order to

make better and timely decisions, decision makers need information on which to base their decisions.

Although recently developed computer technologies, the question still centralizing data, because the makers of an organization is facing a huge data volume (volume of business, but also increases the amount of data) and classical methods become ineffective.

Due to the use computing solution available to them, managers have understood that the data stored in operational systems, including databases, are a gold mine of information to be exploited. Data warehouses have been developed to meet the increased demand for comprehensive analysis, which could not be adequately achieved with operational databases [8].

The emergence of modern IT & C lead to a much faster analysis and better data analysis to be performed in real time.

Traditional databases, called operational or transactional daily operations and help to achieve their main feature is to provide multiple users simultaneously access the data. Operational databases contain detailed data usually do not contain historical data, because they have a high degree of normalization, are performing poorly when trying to execute complex queries such as those involving multiple nested tables or aggregation of large volumes of data. Also, when users want to analyze the behavior of the entire organization, data from different operational systems must be integrated.

Economic organizations must anticipate change and evolution of competitors. For this prediction to be effective, must have accurate and timely information. All organizations have data. They come either from their own operating systems or from external sources. The problem is these organizations to achieve their specific sector, taking decisions based on data they have and how they read.

Data warehouses have been proposed to better meet the demands of a growing number of users coming from the decision-making.

Data warehouses are designed to facilitate reporting and analysis. A data warehouse contains a standard data form, consistent, pure and integrated from various operational systems used in the organization, structured

to specifically address the requirements for reporting and analysis [2].

According to some studies, data warehouses have become, in the late 90's, one of the most important developments in the field of information systems [9].

Data warehouse technology includes a set of concepts and methods that give users useful information for decision making. The building of a data warehouse is apparent from the need to improve the quality of information within the organization [8].

3. OLAP Technology

The concept of OLAP was introduced in 1993 by E. F. Codd when after his research showed that the processing difference between relational and multidimensional model and developed 12 rules that multidimensional analysis systems should follow. E. F. Codd of Computerworld magazine published an article where he said that "however powerful relational systems would be for users, they were not designed to provide powerful features of synthesis, analysis and consolidation of data, functions, known collectively as the Sunbeam multidimensional data analysis.

OLAP technology is characterized by a dynamic multidimensional analysis to assist the end user through a set of activities [4]:

- in-depth analysis (the drill-down);
- achievements can forecast different times;
- use formulas and models on the dimensions and hierarchies;
- extracting a subset of data for viewing;
- Runs in size.

The objective of OLAP technology in an organization is to provide an interactive access, quick and easy access to analytical resources necessary to support decision making and leadership. OLAP tools use simple analytical techniques, namely multidimensional analysis of data for analysis of large data sets.

Specialists in the field believe that a system can be considered an OLAP server with which information is allowed easy access to data (atomic data and derived data) and facilities calculations.

OLAP technology uses data structures called blocks and are organized in multidimensional databases. Defining the structure of cubes is known as dimensional modeling, as well as for designing the data warehouse structure. Because any OLAP cube is used to extract information from a data warehouse cube components are similar to components of a data warehouse.

OLAP technology, multi-dimensional modeling of the backbone. "Multidimensional modeling the results of an economic activity or one or more correlation factors that have participated in their training.

Any application based on OLAP technology has the following characteristics:

- data are presented in the form of cubes, that gives us a multidimensional view of data. For example, where almost all models of economic analysis available to users are multidimensional (eg, models involving libra decomposition of a whole into parts, matter that is based on various criteria: the establishment of the organization, factors of production partners business);

- provides the basis for carrying out complex calculations (with help of specific methods can determine the trend of indicators);

- the ability to make dynamic analysis - regardless of subject analysis results to provide information on times or intervals at which the data relates the analysis;

- concurrent access of a large number of users;

- the application can be used effectively by different categories of users.

4. Data warehouses and OLAP technology

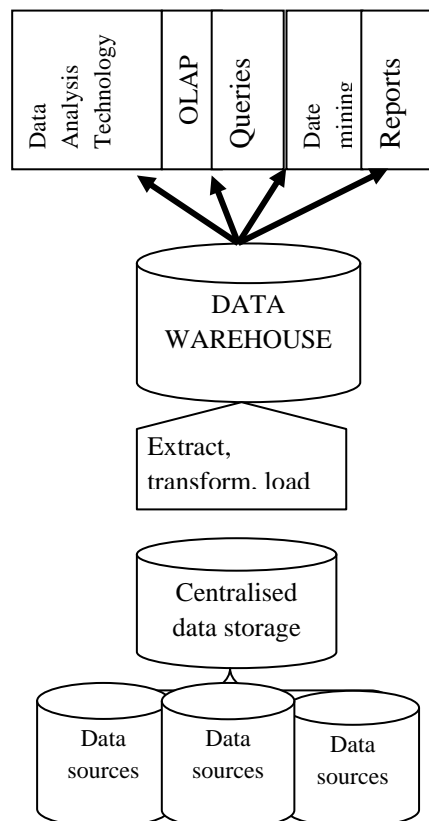

OLAP systems have been integrated within the data-driven decision support although they are hybrid decision support systems, because they use simple analytical techniques (multidimensional data analysis) to analyze large volumes of data. Most industry specialists believe that the data warehouse (data marts) and OLAP tools provide the necessary support to transform large volumes of data that companies working in information useful to decision makers.

The data warehouse focuses more on processes which are insured by the consistency, accuracy and validity of the data, while OLAP systems focusing on requirements and analytical modeling processes and the necessary calculations. Bill Inmon, who has been called the father of the concept of data warehouses has highlighted the idea that the main purpose of a data warehouse is to ensure consistency and accuracy of data used.

Currently, due to fierce competition in the market makers need information to be provided consistently, quickly and easily, which can be secured through the use of analytical tools available to OLAP, data warehouses and the Web facilities.

To better illustrate the relationship between OLAP and data warehouse technology in the following figure is shown a data warehouse architecture.

Fig. 1: An architecture of a data warehouse

Source: Ion Lungu, Adela Bâra, *Sisteme informatice executive*, Editura Ase, București, 2007;

To analyze data stored in the data warehouse using several technologies, most of them used (in terms of actual use but also in terms of existing software support) can include OLAP technology.

The data stored in OLAP technology for data storage is used effectively in on-line data analysis, ensuring a rapid response to complex queries. Multidimensional OLAP model with specific aggregation techniques provide for the organization of large data sets to enable a quick and easy interpretation. OLAP data analysts provide flexibility and speed of work necessary to substantiate decisions in real time.

The relationship between OLAP and data warehouse technology can be defined as: "While data warehouses provide data management, OLAP implements technology that provides strategic information processing such data [6].

The use of OLAP technology provides users with data warehouses several advantages, among which we mention [5]

- rapid execution of queries - because it offers the possibility of storing the values calculated in the cube before performing query such as aggregate values;

- queries based on metadata - for example the MDX is the language that provides native generation of criteria for filtering query results;

- formula similar to those used in spreadsheet applications - one of the advantages afforded by a processor tables is that its users have the ability to generate formulas using cell addresses which are stored values necessary for calculations. OLAP environment and the use of such formula is easily achieved, because the formulas are reachable using any cells address the cube.

5. Conclusions

The importance of a data warehouse is not given by the quantity but the quality of information stored data. Data warehouses have been appointed by Aaron Zornes, a prominent analyst, " data jailhouses " .

Analysis of the data stored in data warehouses would be a very cumbersome process that would not call OLAP technology. Without this technology analysis of deposit would be possible using statistical

models and mathematical methods and time-consuming, with analysis functions developed by developers.

OLAP technology provides valuable data stored in the data store through a more efficient use of the data store.

OLAP tools provide data warehouses along with the transformation of the data bank of information useful to organizations in decision-making.

As a conclusion we can put that into a data warehouse is stored information in order to be able to answer questions like "Who ...?" and " What ...?". OLAP technology is based on a view more sizes to be able to answer questions like "Why ...?" and " What if ...?".

Some Useful Information to Improve the Insertion of the Work Market Process to Students in "Statistics and Economic Foreseeing, and Economic Informatics"

Condrea Elena
Stanciu Anca Cristina
Mirea Mărioara

„Ovidius” University of Constanta, Faculty of Economics Sciences
elenacondrea2003@yahoo.com

Abstract

The paper has in view the achievement of a poll in order to allow the obtainance of information to improve the insertion of the work market process to students in "statistics and economic foreseeing, and economic informatics" - by establishing innovative practice stages.

Specific objectives for the research:

- *The increase of the relevance of the learning results obtained at the work place, by interactive and innovative approaches in the development stages in order to cover the necessary competences and to allow the theoretical knowledge application in concrete psycho-socio-cultural contexts.*
- *Facilitate the transition from school to the real life of the students through participation at innovative programs of practice.*
- *Bringing up-to-date the professional skills of those designated to accomplish the coordination and tutorial activities during the stages.*

Key words: students, statistics, educational process.

J.E.L. classification: C1, I23,

1. Introduction

A nation is competitive either through its economy, but also through its educational offer, respectively the motivation to learn and get continuous specialization of its own citizens. The university represents a primordial institution in order to ensure a long lasting development of a society, being

a provider of knowledge and skills of the specialized workforce.

A first level of the educational process is this where the material, financial and human resources (teachers, administrative employers) are aggregated in an educational service package. At the second level, to the services offer is linked the "student", component important part of the educational process, with specific features. The output of the second educational level is a medium-term output (the specialist in the respective domain), but it is in view a long-term output as well, when more and more specialized personnel is trained.

The paper has in view the achievement of a poll in order to allow the obtainance of information to improve the insertion of the work market process to students in "statistics and economic foreseeing, and economic informatics" - by establishing innovative practice stages.

Specific objectives for the research:

- *The increase of the relevance of the learning results obtained at the work place, by interactive and innovative approaches in the development stages – in the specialization of statistics and economic foreseeing, and economic informatics – in order to cover the necessary competences and to allow the theoretical knowledge application in concrete psycho-socio-cultural contexts.*
- *Facilitate the transition from school to the real life of the students through participation at innovative programs of practice.*
- *Bringing up-to-date the professional skills of those designated to accomplish the coordination and tutorial activities during the stages.*

3. Conclusions

We consider that the proposed paper in linked to this major preoccupation and that it is based on a pull among the students of the Faculty of Economics from "Ovidius" University of Constanta, Romania.

The benefits followed for the target group members are:

- ✚ Identification of the students' performances and skills in the relation with the hiring options and the requirements of the employers concerning the competences in the specializations of statistics and economic foreseeing, and economic informatics;
- ✚ Creation and reinforcement of a partnership network between universities and employers – public institutions and companies – in order to ensure the practice stages;
- ✚ Implementation of practice stages, suitable for the workplaces available from the employers
- ✚ Development of an integrated learning system in order to allow the innovation of the training offers among the academic economic institutions, at national and regional level;
- ✚ Assurance of the conditions for the pragmatic and creative implication of all the trainees in practice stages, in order to make the increasement of the added value in the developed activities like specialists possible.

Internal Audit and Risk Management

Constantin Nicolae Vasile
nicolae.constantin@medu.edu.ro
Alexandru Georgiana
"Spiru Haret" University
georgiana19iu@yahoo.com

Abstract

Internal audit and risk management have the same goal: the control of risk. There are various roles for the internal audit in respect of risk management. The main limitations of internal audit in respect of risk management regards assuming risk management tasks.

One of the main issues regarding risk management is to make sure that the key risks are taken into consideration and that the management and the board of the organization take action as needed. Internal audit could give advice to managers on risk management, making easier the assurance audit activities on this issue, due to the fact that the internal audit and management has agreed on what is being looked for regarding risk management within the organization.

Key words: risk management, internal audit, strategies of risk management.

J.E.L. classification: G32, M41, M42

1. Risk management

Internal audit and risk management have the same goal: the control of risk. There are various roles for the internal audit in respect of risk management. The main limitations of internal audit in respect of risk management regards assuming risk management tasks.

Objectives of internal audit functions differ between organizations, but the main objective should be to assess and improve the efficiency and effectiveness of the management to maintain and improve the internal control system. Objectives might be:

- providing assurance on the adequacy of control system;
- providing assurance on the adequacy of activities;
- advising management.

Risks to internal audit achieving these objectives could be:

- not testing enough to provide the assurance needed;
- incorrect advice.

Risk management could be defined as the activities directed towards the management of opportunities and adverse effects.

The board of the organization is directing the risk strategy, the risk appetite and the risk treatment choices. Risk appetite means how much risk the company wants to take in the achievement of its objectives. Risk treatment means choosing the right options to mitigate the risk.

Within the organization the board, the executive management, the risk committee, the experts and the employees are responsible for the risk management. Nevertheless risk is considered to be the responsibility of operational management.

Important benefits of risk management are:

- increased likelihood of achieving corporate objectives;
- reduced cost of risk;
- calculated risk taking.

Therefore risk management should be *embedded* in the operations of the organizations with appropriate monitoring. Business processes should be *supported* by risk management. The board should have an overall assessment of the contribution of risk management to the function of the business.

There are suggestions that the board should take into consideration the following elements:

- The risks facing the organization;
- The likelihood of the risk;
- The costs of implementing controls to mitigate the risks and the benefits obtained.

There is a difference between the board's role and management and staff responsibilities in respect of risk management.

The board's role is to issue policies for risk management and to see those policies put into place. The executive directors are in charge with the day-to-day operations and therefore responsible for the implementation of the risk management policies. The internal audit should provide advice to the managers.

The board should not just rely on monitoring risk management. It should also receive regularly reports on how the major risks are managed. Also, it should assume an annual evaluation of the process.

The non-executive directors should be have a balanced assessment of the key risks and the controls implemented in order to manage those risks. The internal audit work, which is focused on the major risk areas, could help the non-executive directors figure the assessment.

One of the main issues regarding risk management is to make sure that the key risks are taken into consideration and that the management and the board of the organization take action as needed. In order to accomplish these important corporations set up a risk management committee.

The main roles of the risk committee are to:

1. report on the key risks to the board;
2. review how the major risks are managed;
3. promote the best practice in risk management within the organization.

In the public sector, a lot has been done on risk management in latest years. There were created risk committees, codes of conduct and the requirement for statements embracing the risk and control.

The main risk management strategies are to:

- avoid/transfer it – get rid of the activities giving rise to the risk. Avoiding an activity is the answer to a risk that cannot be controlled. Some organizations, for example, taxi companies have identified no-go areas where their cars will not go. Public sector organizations instead do not have sometimes the choice of avoiding a risky activity.

- reduce/exploit it – insure against the risk; Insuring against a risk will reduce the financial impact but is not going to solve the problems created by business discontinuity. Nowadays, insurers require organizations to treat risks using internal controls as well as insuring against it. The insurance might cover above a certain level of excess.

- retain it – implement controls to manage the risk.

The greatest number of risks will be retained. Internal controls will be implemented to mitigate reduce either the probability or the impact. Organizations retain risks where controls have brought them to accepted residual levels.

The strategy an organization takes to mitigate risks should take into account the risk tolerance decided upon. Line management should take into consideration their key risks and chose which of these strategies is adopted. Sometime a mixture of the three strategies is needed to be implemented.

The internal audit function has various roles and responsibilities regarding the risk management process in an organization.

The corporate failures and the growth of enterprise risk management programs determined nowadays the internal auditors to be actively involved in the risk management efforts of the organization.

It is important to clarify how the internal audit can assess the adequacy and effectiveness of an organization's risk management efforts. However, it is important to underline that risk management it is a management responsibility.

In this respect, the role of the internal auditors is to assist management by providing advice regarding risks.

In those organizations that have an internal audit function and risk management process it is vital to be sure that there is no duplication of work. Therefore, it is crucial that the roles of each function is made clear to stay away from unjustified overlap and, more importantly, to avoid conflict of interests.

2. Roles for internal audit within the risk management process

There are many roles that internal audit can fulfill in respect of the risk management process implemented within the organization.

The role assumed depends on the organization and may change over time. There are spreads of activities the internal audit can perform in these respect, such as:

- auditing the risk management process;
- supporting the risk management process;
- participation in risk management committees;
- performing monitoring activities;
- facilitating risk workshops.

Today, internal audit assumes at least two important roles in respect of the risk management. First, internal audit can act as an advisor helping the organization in respect of risk awareness. This can be done by improving the management understanding of the major risks facing the organization. It should be mention that the risk management process can be used by internal auditors in identifying areas for review. In these ways the internal auditors can focus their activity on the key systems and controls within the organization.

Second, internal auditors can act as trainers in risk management workshops. In this way internal auditors aid line managers understand better organizational risks and controls. This is how internal audit can help the managers to identify various risks.

It should be taken into consideration that a specific risk management function is created in many organizations. In this organizations, there is appointed a risk manager, how advises top management on the risks and the ways in which they can be managed. In these cases the internal auditor can provide on the one hand advice and on the other hand assurance on the risk management process.

There are a number of steps that the internal audit function needs to take to be sure that risk-based audit works. The first is for internal audit to work with the risk management function. By working together, the internal audit can get experience from risk managers in those areas that affect its independence. Of course, the management support is vital if risk-based auditing is to work.

3. The role of internal audit in assessing the risk management process

The internal audit can assess the risk management processes of the organization at the strategic and operational level.

Within an organization, the internal audit can assess the effectiveness of the policies and processes implemented.

Internal auditors can participate in committees in order to provide expertise to management regarding risks. Of course, internal auditors should not be directly involved in risk management. This could allow internal auditors to improve their knowledge on management issues and to recommend the implementation of controls tailored to the organization's needs.

Middle-level managers may also benefit from the advice of internal audit in respect of risks. However, internal auditors need to maintain their objectivity. This is way the management should be aware of the impairments to independence and objectivity with regard to non-audit work.

Internal audit could give advice to managers on risk management, making easier the assurance audit activities on this issue, due to the fact that the internal audit and management has agreed on what is being looked for regarding risk management within the organization.

The organization's board might request the internal audit to perform activities away from its usual role of providing assurance to a more consultative role that risk management performs as expected.

4. The involvement of internal audit in the risk management process

The involvement of internal audit in the risk management process is different from one organization to another. There are entities which have risk management functions and there are entities where the internal audit proposes the policies adopted in this field.

There are a number of ways in which internal audit could get involved in the risk management process without impairing its independence and objectivity, as follows:

- organizing workshops meant to provide training to the line staff with regard to the risk management process;
- providing expertise as members of teams appointed to provide solutions on risk management;
- Assessing the risk management process and issuing recommendations on this area.

Nevertheless, it should be mentioned that the internal audit can't assume and be responsible for effectiveness of risk management. That is the responsibility of the top management and operational management. Assurance on the risk management process can, however, be provided by the internal audit. During the assessment activities, internal audit can also give advice on this field.

Internal auditors have to meet the assurance needs of their organization.

The trend of internal auditors providing assurance on risk management process is relatively new. Of course, it's not the same as risk-based auditing. Also, nowadays, it's not limited to corporations that have to obey Sarbanes-Oxley, and it's not something that only internal auditors from the big companies have to do. It should be mentioned that a large corporation has led the way, but over time they brought many other organizations with them.

The various approaches and tools developed by internal audit functions within big organizations are followed by smaller internal audit groups. In practice, this means getting a better understanding of the company's risk profile, spotting changes and addressing new kinds of risks.

There is a change in the way internal auditors take into consideration the risk. Traditionally, internal auditors focused on the probability that the risk would arise. In the years ahead internal auditors will have to be concerned more and more about the vulnerability created by the risk. This is the consequence of the fact that in the past years low-probability risks have brought down important corporations.

Sound risk management can be helpful for internal auditors trying to establish the best balance of assuring and consultancy activities. This might be taken into consideration in designing the audit plan. The audit plan could be more assurance based,

due to the fact that internal auditors consider that the organization has low vulnerability, or could be focus more on a consultative kind of audit.

In the 1980's internal audit was mainly focused on compliance activities, but nowadays the internal audit is more and more focused on consultancy. The future has to balance both approaches in order to provide value to the organization.

The internal audit's key objective of reviewing the internal control system will be achieved by reviewing the effectiveness of the risk management process. The internal audit should give an independent view of the risk management and its effectiveness in mitigating the major risks facing the organization.

Sometimes the chief audit executive is also in charge to propose the internal controls and the risk management system that should be implemented by the organization and might then help the unit to put into practice the policy. Internal audit could get together the results of the risk management process and report to the board on the key risks facing the organization.

Therefore, it is very important for the board of the organization to understand that risk management and internal audit are there to provide assurance on risks facing the business – but they will do so in entirely different ways.

The Status of Women in the History of Economic Thought

Cosma Sorinel

„Ovidius” University of Constanta, Faculty of Economic Sciences
sorinelcosma@yahoo.fr

Abstract

The economic and social status of women has been a topic of considerable interest for many philosophers and economists ever since ancient times. Then as now, the disputes that arose had as much to do with broader political considerations as with simple economic analysis.

Key words: women's status, history of economic thought.

J.E.L. classification: N00

1. The Status of Women in Classical Athens

The status of women in the 5th and 4th century Athens was very low. They were an economic commodity that men could move in and out of marriages.

Plato (c 428-355 BC) wrote some works on the ideal construction of government and laws. In his *Republic*, he described an ideal, but highly utopian, form of government in which the state would be governed by guardians – talented and well trained men and women. For him, the skill of governing was not gender defined. Some men and women have an aptitude for governing, others do not. He saw no reason why women could not hold the highest offices in the polis.

Plato believed that laws should apply equally to men and to women. And so should education. He reasoned that women and men each represented half the population. If only boys were to be educated, it took the same effort and expense, but in the end only half of the population was educated.

In his work, there is a gender distinction – in terms of military service. Though girls would receive the same military training as boys and serve under the same regulations, they would serve from the end of their

childbearing years to age fifty, whereas men would serve from age 20 to 60. And since women performed military service, they would be able to participate in government and be officials.

Plato promoted the equality of women and men and believed that gender had nothing to do with the ability to govern. But **Aristotle**, Plato's student, believed that women were inferior to men and needed to be governed by them. He believed women were not full persons. The system proposed by Aristotle did not allow any public role for women. He thought men were by nature superior and were made to rule, while women were inferior and made to be ruled. Men had reason and intelligence. Women had them also, but less in quantity and different in quality.

Aristotle advocated some education for women, but only to enhance the quality of the household and of the state. Within the household, there were three relationships: master and slave, husband and wife, father and children, and the man was the first in all three of them.

If Plato used Socrates in his dialogue to support sex unity, in another dialogue – *Oeconomicus* - **Xenophon** (c 430-357 BC) used Socrates to do exactly the opposite, to support sex polarity. Because ideas about gender vary according to historical context, the *Oeconomicus* has been given different receptions over the years. In the modern era, the status of Ischomachus' wife has been persistently misunderstood by feminist as well as traditional scholars.

In his work, Xenophon asserts that women and men are complementary in their biological nature, and therefore in their contributions to the domestic economy, but this difference does not imply inequity. They are complementary in estate management as well.

Like Plato in the *Republic*, Xenophon makes it clear that the soul has no sex; men and women are endowed with a potential for moral equality.

His dialogue contains a great deal of information of interest to the concept of woman. For example, the husband is responsible for the quality of the wife's work on the estate. He should instruct her, if he does not he is to blame; and if she is well-instructed but does not do a good job, then she is to blame.

Isomachus draws a rigid distinction between public and private spheres of activity through the bodily potential of the sexes and through divine ordaining. Thus, Xenophon was the first philosopher to offer detailed arguments for the separation of virtues for men and women.

2. Classical Economists and the Status of Women

With few exceptions, such as **John Stuart Mill** (1806-1873), classical economists are generally held to have focused on the activities of men in markets, to the neglect of women's status. In some cases, (**Smith, Bentham**), this is partly due to the fact that these ideas were not published in their most prominent contributions.

In the case of **Adam Smith**, he analyzed the evolution of the status of women across four historic stages of economic development (the ages of hunters, pasture, agriculture and commerce.), but this analysis of his appeared in his work *Lectures on Jurisprudence*. Central to the argument that underpinned this history was the notion that while biological differences between the sexes are a constant, the social significance of these differences is a variable. Smith focused on the respective physical strength of men and women and on women's capacity to give birth, arguing that the relationship between these factors and the mode of subsistence is a key influence on gender status. Most importantly, Smith suggested that the further development of commerce and industry would lessen the importance of physical differences, making possible further improvement in women's social and economic position.

Women did work for pay in Adam Smith's Scotland, as they did elsewhere in Europe, although the *Wealth of Nations* pays them little attention.

But it has been concluded that Smith had relatively little confidence in women's independent judgment and hence in their capacity for reasoned decisions on economic matters.

Jeremy Bentham's thoughts on the relations between the sexes were scattered across assorted publications and manuscripts, which greatly lessened their impact.

Jeremy Bentham's dictum "Let There be no Distinction between the Sexes" sums up his thoughts on relations between the sexes. Bentham's utilitarianism treated women and men as equals, with equally valid preferences and equal capacity to act rationally in their own interests.

3. François Poulain de la Barre

During the second half of the 17th century, European liberals began constructing a theoretical foundation for "the rights of man", meaning by this the rights of men.

Writer, Cartesian and feminist philosopher, **François Poulain de la Barre** (1647-1725) was a pioneer in the history of economic thought by applying the deductive method of analysis to the study of women's social position. A disciple of Descartes, he wrote three rationalist tracts between 1673 and 1675 which cogently argued the case for equality of the sexes.

He was able to highlight the fact that the claim that women are men's social subordinates (because they are naturally less productive) was in many cases merely a product of prejudice. He also challenged the assertion that the biological differences between the sexes fixed forever the relative economic and social status of men and women.

Wishing to illustrate the value of Descartes' methodology, he reasoned that refuting an assumption so widely accepted as was the claim that women were innately inferior to men would encourage scholars to recognize the need to reject beliefs based only on appearances or the world of authorities.

He started with the readings and interpretations of the Bible, more precisely the interpretation of the 'curse' God supposedly pronounced against Eve at the time of the Fall.

After denying that the origins of women's subordination were divine in character, Poulain searched to develop an explanation for how it could be that external conditions were created that enabled men to discriminate against women – what he called 'historical conjecture'.

He started from the axiom that human beings will impose their will upon others given the opportunity and chance to benefit by so doing. He then deduced that men used their greater physical strength to impose their will upon females, in a primitive world when there was no government and there was an abundance of material resources. Women's ability to match men's contributions in the production of economic goods would have been undermined by their role in reproduction.

As population grew, per capita resources became scarce, and conflicts were generated in both the home and between communities. Poulain suggested that once competition for the available economic resources reached the stage where communities were compelled to fight for the right to utilize them, we have the beginning of warfare, slavery and social subordination of women. That is because women became reliant on the warriors for their immediate physical security, their freedom from slavery and their ability to attain their subsistence. Not being involved in conquest and defense, they had little say in the government of society.

From here it was an easy step for men to believe that, apart from the ability to give birth, women's capacities were inferior to those of men, and women did not have the intellectual or spiritual capacity to rule. In time, this prejudice became self-evident truth.

Poulain's contribution is significant in terms of the development of economic theory and methodology. Still many failed to see it when studying his work.

4. John Locke's analysis of gender relations

Apart from his contributions to the development of economics in the area of monetary and property theory, **John Locke** is also credited for pioneering research into the economics of the social position of women.

Locke developed his analysis of gender relations as a consequence of his involvement in the liberal critique of regal absolutism and the divine rights of the monarchy. He observed that in the Bible the word 'them' is used when stating to whom dominion of the earth was initially given. So, God had not given sole regency of the world to Adam. When Adam and Eve were driven from Paradise, both were being punished. The fact that Eve was subjected to greater punishment than Adam did not give him superiority over her. Rather, he obtained some form of material advantage. In short, he gained a capacity, not a right to rule.

Locke explained women's subordination to men by the males' greater innate abilities and strengths. He denied there was any difference between the minds of males and females as regards their capacity to comprehend truth. He believed the mental capacities of the two sexes to be so alike that there was no reason why both should not receive an identical programme of education.

To comprehend Locke's argument regarding the status of husband and wife, it is also necessary to understand his theory of the origin of private property, his justification for the uneven distribution of property within society and his understanding of the relation between property-owning partners.

By property he understood property that men have in their persons (life, liberty, capacity to labor), as well as goods. This leads to the idea that all individuals own some property, even if this is no more than their life, liberty or capacity to work. Locke also recognized the equal right of all individuals to be free of arbitrary domination.

As far as inequity is concerned, Locke admitted that some individuals can labor more productively than others. He also pointed out that when people chose durable metals (with little intrinsic capacity to sustain life) as the primary instrument of exchange, they chose to support the unlimited

accumulation of wealth and the uneven distribution of the world's resources.

As a result, the partners in a relationship are not necessarily equal. The relative standing of partners depends on the quantity of property each puts into the relationship and the respective degree of need each has for the other.

5. The Status of Women during the Victorian Age

Legally, married women during the **Victorian period** had rights similar to the rights of children. The law regarded a married couple as one person, the husband being responsible for his wife and bound by law to protect her, and the wife being supposed to obey him. Women in those times were consequently trying to gain their own voice. Women wanted equality with men; they wanted a right and the opportunity to have equal education. They were interested in education in that they wanted to learn the same things that men were learning and no longer be educated in domestic necessities. Women were supposed to exist only in the domestic sphere. They were supposed to raise the children and make sure that the household ran smoothly; they were also to be the moral conscience of men. Also, men did not believe that women had the capacity or the will to understand politics. So, women were fighting for their legal identity in that period. They were trying to gain rights to their property and their children.

John Stuart Mill was the most prestigious radical writer in England and the most prestigious name to be associated with the cause of women's social and political advancement.

The Subjection of Women by John Stuart Mill was a cornerstone in the fight for equality between the sexes. In this essay Mill was exploring the "Women Question" and the role women had in English society. He attacks the notion that women are inferior to men. Mill argues that there is a full half of the population being constrained by societal gender-roles and that it is unfavorable for society in that it is somewhat preventing societal advancement by not allowing a free-flow of ideas.

The *Subjection of Women* is about much more than woman suffrage – it is an incisive analysis of women's degraded position in society, describing in great detail the manifold ways in which patriarchy operates and how men's dominance of women corrupts both men and women.

The first chapter contains Mill's argument about why the existing and long time social subordination of women should not be taken as any evidence in favor of the proposition that this arrangement is for the best. The second presents an argument against the 19th century subordination of women in marriage. The third presents evidence of the competence of women to do many of the jobs from they were by custom (and law, in some cases) barred. The final chapter addresses the most important question, for a utilitarian, to wit, what is the gain in human happiness that is to be secured by the social emancipation of women?

Mill compares the domination of women to slavery. Women are forced to submit to the will of their husbands and have no say in their lives. Women cannot change their position because they rely on their husbands for everything they are given. They have no right to money or even to govern their own children without the permission of their husbands. Women cannot maneuver in their society without the help of men because they have no rights.

What is very interesting, Mill used in his essay examples of ancient societies that thought women capable of intellect and that did not hold women subordinate by law. Ancient civilizations that he cited to show the capability of women include the Greeks and the Spartans.

6. Conclusions

Plato, Aristotle, Xenophon, Poulain de la Barre, Locke, and Mill are only a couple of examples of great men who were drawn to writing about the status of women in society. Though they lived and wrote during different periods in our history, and though they were driven by different reasons when doing so, their analyses shed light on the topic and can be used as starting point in any feminist argument.

Water as a Global Public Good

Cosma Sorinel

„Ovidius” University of Constanta, Faculty of Economic Sciences
sorinelcosma@yahoo.fr

Abstract

Water, like many natural resources, has been conceptualized — and managed — as either a public good or a commodity. The United Nations Committee on Economic, Cultural and Social Rights issued a statement declaring access to water a human right and stating that water is a social and cultural good, not merely an economic commodity. Ensuring that the public receives an adequate supply of public goods requires some level of government responsibilities and action, since purely private markets often do not find it profitable to provide public goods. Often provided at subsidized prices or for free in many situations, water is available to even the poorest segments of society.

Key words: Global Public Good, water, privatization, crisis.

J.E.L classification: O13

1. The Concept of Global Public Goods (GPGs)

During recent years, the concept of **Global Public Goods (GPGs)** has become an increasingly important part of international policy making. The notion of global public goods appeared sometime in the early 1990s in the context of global environmental issues.

The concept appears in the agendas of UN agencies, the IMF/ World Bank, and Non-governmental organizations. Everyone depends on public goods, neither markets nor the wealthiest person can do without them. Clean environment, health, knowledge, property rights, peace and security are all examples of public goods that could be made global.

Most goods in the world are "private" in the sense that their consumption can be withheld until a payment is made in exchange for them, and once consumed they

cannot be consumed again. In contrast, once "public" goods are provided no one can be excluded from consuming them and one person's consumption of them does not prevent anyone else's. The provision of public goods is central to securing human well-being. But, given their characteristics, public goods are open to free-riding and vulnerable to what is known as the 'failure of collective action'.

A **global public good** is therefore a good that is *non-rivalrous*, *non-excludable*, and it is *available worldwide*. GPGs are unlimited by national boundaries, but cross over into sub-regional, regional and global spheres. They are public goods - commodities for which the cost of extending the service to an additional person is zero - where the effects spill widely around the world and for a long time to come.

The concept of **GPG** is an extension of Samuelson's notion of public goods to the economics of globalization. In 1954, in two and one-half pages writing on public goods, Paul Samuelson reshaped the way economists and political philosophers think about the distinction between private goods and public goods. In some academic literature the concept of global public good has become associated with the concept of a common heritage of mankind.

Knowledge is a canonical example of a global public good.

Many **GPGs** have historically existed outside of human interference, such as the oceans and seas, the atmosphere, and ozone layer, whilst other GPGs have emerged as different aspects of globalization have advanced. GPGs cover global issues that range across the whole spectrum of the sustainable development agenda, from the global environment, international financial stability and market efficiency, to health, knowledge, peace and security and humanitarian rights.

Street signs, global positioning systems are a good examples.

For the case of **global public goods**, there exists today no workable market or governmental mechanism that is appropriate for the problems. There is no mechanism by which global citizens can make binding collective decisions to slow global warming, to cure overfishing, to efficiently combat AIDS, to form a world army to combat dangerous tyrants, or to rein in dangerous nuclear technologies.

The concept of **global public goods** helps us respond to the new global challenges of the twenty-first century. In the light of globalization, a term that now permeates everyday language, people's well-being does not depend only on the provision of public goods by national governments, but increasingly depends on the provision of global public goods that only international cooperation can secure.

The supply of these **GPGs** depends on the willingness and ability of countries to devote national resources to domestic objectives that also contribute to international purposes and goals. In the absence of an international body endowed with the power of levying taxes to finance **global public goods** or endowed with the power of making enforceable laws to provide them, voluntary co-operation and global collective action are currently the only two ways of ensuring supply of **global public goods**.

2. Water World Statistics

Fresh water accounts for only 2.5% of the Earth's water supply, the rest 97.5% being salt water. The 2.5% are made up of glaciers and polar ice caps (68.9%), lakes and rivers (0.3%), and groundwater (30.8%).

12 percent of the world's population uses 85 percent of its water, and these 12 percent do not live in the Third World.

Vast amounts of water are used to produce food, clothes and other consumer goods.

Industrial agriculture damages the environment through massive water consumption. It is recommended that governments put agriculture at the centre of an integrated policy response and invest in more carbon efficient systems, which conserve water and address the concerns of small-holder farmers.

Bad water kills more people than wars or earthquakes. One billion people worldwide do not have access to safe drinking water and 2.5 billion are lacking safe sanitation. Some 3.6 million people are estimated to die each year from water-related diseases.

Water consumption is doubling every 20 years and yet at the same time, water sources are rapidly being polluted, depleted, diverted and exploited by corporate interests ranging from industrial agriculture and manufacturing to electricity production and mining. With water tables falling, rivers drying out and salt pollution of groundwater rising across the world, global fresh water resources become increasingly scarce.

Climate change will only worsen the problem.

According to UN figures, by 2015, 1.8 billion people will not have access to water. Other estimations claim that, by the year 2025, two-thirds of the world's population will face water scarcity.

It is argued that public water provision is key to "tackling the global water crisis" and promoting development.

As consumers of goods produced in poor countries, wealthy nations bear responsibility for contaminating and using up poor country water resources.

3. Water Privatization

Water has historically been considered a "public good," however, in recent years governments and businesses have begun treating it as an "economic good," promoting privatization in both poor and rich countries. Emerging water markets are changing the nature and structure of how our water supply is managed. It is becoming profitable for states to buy the rights to water in a foreign place.

Though privatization is functioning in some rich countries, it creates a slew of problems in poor countries, where fair contracts are harder to negotiate and people are more desperate. Many argue that privatization serves the interests of unaccountable multinational corporations rather than creating an engine of growth. Because once private water giants take over water services, prices skyrocket.

Also, if allowed, private water companies will favor richer customers, shift risks back to the government and invest as little as possible. In too many cases, companies have repeatedly renegotiated their original contract to increase rates or get out of requirements to connect poor neighborhoods. Governments that turn to privatization will need a lot of help from international institutions if they are to play the strong regulatory role required to make a privately run system a success.

Across the globe, the World Bank, the International Monetary Fund (IMF) and multinational corporations are pushing poor countries to privatize their water resources.

Currently there is a rush to privatize water services around the world. Countries faced with large debts are forced by the World Bank and IMF to privatize water. Water deregulation is a common demand of the World Bank and IMF as part of their loan conditions.

The World Bank and International Monetary Fund (IMF) are pushing for the privatization of water services by European and U.S.-based companies. They are pushing privatization through stipulations in trade agreements and loan conditions to developing countries. These privatization programs started in the early 1990's and have since emerged in India, Bolivia, Chile, Argentina, Nigeria, Mexico, Malaysia, Australia, and the Philippines, to name a few.

Since 1990, water privatization - turning over some or all of the assets of a public system to a private company - has been growing rapidly. Globally, more than 90% of water and sanitation systems are publicly owned and operated.

According to the World Bank, in 2007, 84 percent of water systems privatized in the 1990s were still under private control. 24 countries have regained public management of their water systems.

The number of people served by private companies has grown from 51 million people in 1990 to nearly 300 million in 2002. Six water companies alone expanded from 12 countries in 1990 to over 56 countries by 2002.

Privatization turns water into a commodity and abolishes water as a human right. Without public control, poor people will not have access to clean water and sanitation. Since the 1990s, many countries have handed

over water management to private companies. Water became a commodity instead of a public good, leaving millions of poor people without access to safe drinking water and sanitation. And as water resources dwindle, conflicts over water intensify. In Bolivia, South Africa, Ghana, the Philippines and Indonesia violent struggles have broken out against companies seeking to privatize water. About 175 people were injured, two were blinded by the gas, more than 50 people were detained a boy was shot dead and six people were killed in protests in 2000 in Cochabamba, Bolivia, where the newly privatized water company, a subsidiary of Bechtel, substantially immediately modified the rate structure and it increased water rates as much as 200 percent, which the company claimed was necessary to cover the costs of planned extensions and upgrades to existing infrastructure.

Water is the oil of the 21 century. Corporations are rushing to invest in the water business, having made plans to buy water rights, privatize publicly owned water systems, promote bottled water, and sell "bulk" water by transporting it from water rich areas to markets desperate for more water. For example, companies like Coca-Cola are selling purified tap water as a healthy option, and they believe that in the long run selling water will be more profitable than selling Coke.

The commoditization of water is the main reason for the **water crisis**. Promoting water as a commodity has led to increased control of water by multinational corporations whose main responsibility is to increase the shareholder's profits to the expense of many people who are too poor to afford it.

The World Bank and the other international institutions took on neoliberalism, and encouraged privatization of most resources. In other words, they attempted to put a price on everything, even if it was not appropriate, e.g. health, education, and, possibly, water, amongst other services. It was hoped that efficiency would increase and subsidies for such provisions would be removed. In doing so, the poor have found themselves being shut out as prices have risen beyond affordability. When confronted about the water crisis, the World Bank argues that the problem is not

privatization itself, but improperly practiced privatization.

The private sector proves to be unreliable in this area because of two main aspects. Firstly, in the absence of a strong regulatory capacity to protect the public interest through rules on pricing and investment, the water sector develops many of the characteristics of a natural monopoly, with real dangers of monopolistic abuse. Secondly, in countries with high levels of poverty, money is an issue, regardless of whether the provider is public or private.

4. Conclusions

Water is a human right. Article 25 of the United Nations Declaration of Human Rights notes that "Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing and medical care and necessary social services, and the right to security in the event of ... circumstances beyond his control."

While water is not mentioned explicitly, the right to food includes water as well, because water is essential for humans to live, and is therefore in line with the principles of the declaration.

Water management—not water scarcity—is the problem and that calls for new ethics.

In terms of privatization, water should remain a common property resource, common heritage of all. Other solutions such as eco-sanitation and rainwater harvesting should be pursued. However, there may be costs associated with being able to provide the infrastructure and services in a sustainable way.

Water, this 'blue gold', has become an unavoidable issue. The global water crisis is the biggest challenge facing the international community.

Quantification and Reflection of Economic Operations with Goods and Services in National Accounts

Coștuleanu Carmen Luiza
„Petre Andrei” University of Iași, Faculty of Economics
ccostuleanu@yahoo.com

Abstract

The economic operations quantified and reflected in national accounting, consisting in income and expenditure flows, are classified in operation accounts, according to their intrinsic nature.

These are display accounts that allow a decomposition of the relationship existing between two institutional sectors more detailed than that offered by sector accounts.

Although a nation's economy includes an impressive number of economic operations, they can be regrouped into three main categories that are: operations with goods and services, distribution operations and financial operations.

Operations with goods and services represent mainly one of the three categories of economic operations.

Key words: national accounting, income flows, expenditure flows, goods and services, macroeconomics.

J.E.L. classification: A10, E01, E21, E23, M41.

1. Introduction

The economic operations quantified and reflected in national accounting, consisting in income and expenditure flows, are classified according to their intrinsic nature. By this criterion, although a nation's economy includes an impressive number of economic operations, they can be regrouped (structured) into three main categories that are: (i) operations with goods and services; (ii) distribution operations; and (iii) financial operations.

The operations which describe economic flows are grouped by the nature of the economic activity reflected in operation accounts. These are display accounts that

allow a decomposition of the relationship existing between two institutional sectors more detailed than that offered by sector accounts.

2. Operations with goods and services

Operations with goods and services represent one of the three categories of economic operations. Operations are economic flows while operation accounts regroup identical economic operations developed by various institutional units [1].

Operations with goods and services refer, on the one hand, on their origin or provenience, that is production (P) and import (I), and on the other to their final use, respectively consumption (intermediate and final), gross fixed capital formation (GFCF), valuable objects, stock variation and export.

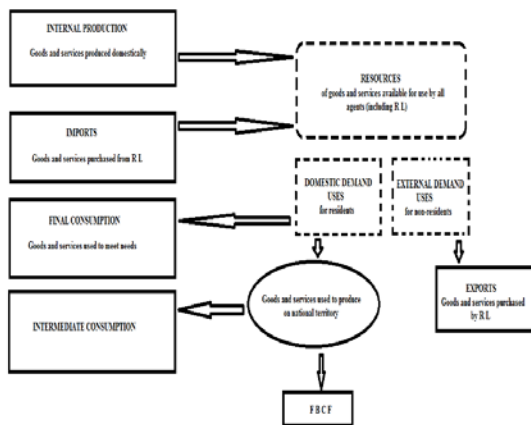

The macroeconomic balance described by national accounts and founded on operations with goods and services presents as follows: $P + I = C + GFCF + E + \Delta S$, where P=production, I=import, C=consumption, GFCF=gross fixed capital formation, E=export and ΔS =stock variation.

The relationship above would be translated by the fact that the total amount of available quantities of goods and services (production + import) is necessarily equal with the total amount of use: consumption (intermediate and final) + gross capital formation (GFCF + valuable objects + stock variation) + exports. Thus, the total of resources is always equal with the total of uses (figure 1).

Production is an activity consisting in manufacturing goods or providing services under the control and the responsibility of an institutional unit. Within this activity, the institutional unit employs a combination of production factors, workforce and capital and "consumes" goods and services. Production is thus the result of this activity [1].

According to the operation nomenclature of the SCN, the production realised by resident institutional units has two components in its structure: production for the market (merchandise) and production not for the market (non-merchandise).

Figure 1. Operations with goods and services

Source: [1].

Production for the market (market production) is the production destined to market exchange or that which is likely to be exchanged on the market at a price that should cover at least the production costs. The price of merchandise production may take various forms: royalties, cession prices, voluntary fees, etc.

Production for the market may include both goods for the market and services for the market, as follows:

1. *production of goods for the market*; it is conventionally considered that all the goods are for sale. Are excepted from this rule only the goods that are used by the producer to cover its own consumption needs, such as, for example:

- for intermediate consumption (thermal energy produced by a power station and consumed by itself);
- for final consumption (the part of agricultural production obtained by farmers and used by themselves);
- for gross fixed capital formation (fixed assets created by economic units through their own efforts);

2. *production of services for the market*; merchandise-services are represented by the services sold in various forms (reparations,

advertising, consultancy, financial brokerage services; etc).

The revenues gained by the units that have services as their object of activity come from:

- commercial margin-generated by the services produced by the commerce branch and determined as residual between the selling price without the VAT and the purchase prices without the VAT;

- rental services-the estimation of a fictitious rent obtained if they rented their own building. Rent-real or fictitious-is payment for a service rendered (rent) and not a revenue on the property owned that would generate a distribution operation;

- services sold at their residual value refer to the services provided by government and sold at the cost of factors, not that of the market (for example, preschool canteens).

Production not for the market, non-merchandise (non-market production) includes two categories of such production:

1. *production for final self-consumption* that is developed by institutional unities for final self-use. It refers to the goods or services that an institutional unit produces and preserves for its own final consumption or for its own gross fixed capital formation. Such a production is mainly provided by the people's houses/households and consists in the production of housing services and domestic services, along with the cultivation of agricultural goods, and by enterprises in the form of equipments for their own use.

2. *other non-market production* that is provided for others but financed by the producer itself, especially by public administrations and IFSLSGP. It is defined as the production provided to other units either for free or at an insignificant economic price, which covers less than half of production costs.

Consumption

Obtaining a product is closely connected with developing *consumption*. By consumption we understand using a good or service with the purpose of obtaining other goods or in order to satisfy certain human needs.

In its turn, consumption takes two forms: intermediate consumption and final consumption.

Intermediate consumption is produced by the consumption of commercial goods and services coming from other institutional units

and employed in the production process; it is the "value of the goods and services transformed or entirely consumed during the production process". Intermediate consumption differs from final consumption by the fact that it is productive, contributing to the production of goods and services with a less than a year life-cycle (circulating assets), while final consumption is unproductive because it does not leave to the production of new products.

Final consumption is produced by the consumption of goods and services employed to meet individual (final consumption of households/houses) or collective (final consumption of public and private government and of IFSLSGP) human needs.

Final consumption may take the form of the final consumption of merchandise or commercial goods and services and of the final consumption of non-merchandise or non-commercial services.

According to SEC'95, we distinguish two concepts in what regards final consumption: final consumption expenditure and actual final consumption.

The concept of final consumption expenditure refers to the expenditure approved by a sector in order to purchase goods and service for consumption while those of actual final consumption refer to the purchase of goods and services for consumption by a sector. The difference between the two notions consists in the treatment applied to a number of goods and services which are financed by public administrations and households and are provided by the latter in the form of social transfers in kind.

Gross fixed capital formation (GFCF)

Is an indicator that reflects the value of the goods and services purchased or produced within the resident unit employed in the production process during a period of over a year.

In national economy there is a wide array of ways in which gross fixed capital forms, from which we may distinguish [2]:

a. purchasing (less those that are out of use) new fixed assets or extending the old ones, grouped as follows:

- living quarters;
- other buildings and structures;
- machines and equipments;

- livestock and fruit plantations.

b. purchasing (less those that are out of use) new intangible fixed assets or from existing ones, grouped in:

- mineral explorations;
- computer programs (software) and development projects;
- licences, patents, copyright, etc., for the production of shows, for literature or for artistic originalities;
- other non-corporate assets.

c. major investment in non-productive tangible assets, including in land;

d. the cost associated with the property transfers of non-productive assets.

In a general manner, the coherence of the new GFCF notions might be doubted, because it excludes research-development expenses but it integrates the purchase of durables such as weapons when they cannot have a civil use (weaponry or ammunition are excluded because, in order to be durable, goods must not be usable only once, such as bombs, grenades, etc... – these expenses are considered to be intermediate consumption), the troops' housing is included into the GFCF.

In 2009, Romania's GFCF included: 26% industrial equipments, 47% buildings and 27% services.

Valuable objects

The new system introduces a new concept named valuable objects. These objects are represented by precious metals and gemstones, jewellery, art objects. These goods cannot be included into the GFCF because they are not usable in a production process and cannot be considered as final consumption either because their value does not depreciate in time as their main purpose is to become value reserves. As goods and services use, these objects are registered as purchases without cession.

Stock variation (ΔS)

Stock variation represents the difference between the value of stock inflows and stock outflows during the financial year:

$$\Delta S = \text{Inflows} - \text{Outflows.}$$

It is the last possible use for a product. The concept would be more appreciated if we mentioned that stock variation does not represent the variation of stock value during the financial year. A product's stock value is

always determined at the market prices available on a given day (so it is a potential value: the amount that would be redeemed if all the stocks were sold). This value may vary in the course of a given period because the market prices of stock items change. In order to delimit this variation we talk about stock appreciation or depreciation [3].

These stock value increases or decreases are taken into account in inventory variation accounts.

Operations with the rest of the world

This category includes all the operations with merchandise goods and services carried out between resident units and the rest of the world (non-resident units). In other words, we are talking about exports and imports of goods and services.

Exports refer to goods and services that leave the national territory for good, being the result of resident institutional units and making the object of a transaction between these and non-resident units.

This category also includes the goods and services consumed by households that do not have their residence on the national economic territory (for example, tourists, diplomats, etc.).

Imports represent the inflows of goods and services created by non-resident units and purchased by units that reside on a nation's economic territory. They include goods and services consumed by households situated on the foreign economic territory.

3. Conclusions

Operations with goods and services refer, on the one hand, on their origin or provenience, that is production and import, and on the other to their final use, respectively consumption, gross fixed capital formation, valuable objects, stock variation and export.

Operations with goods and services represent mainly one of the three categories of economic operations.

The Efficiency of Applied Strategy Management Based on Knowledge

Crăciun Bucur Matei

Academy of Economic Studies, Bucharest

mbc@mmsynergy.ro

Abstract

Global requirements, general economics and world business, are subject to rapid change. In such stormy conditions, strategic management must pro-actively intervene.

The economic areas and the current scientific use increasingly more lately knowledge and knowledge management theme. Knowledge of central significance for gaining competitive success through focused knowledge management. A long survival in the competition can only stand as passing knowledge management as one of the key strategic features of the company.

Key words: *management, implementation, consulting, economy, learning*

J.E.L. classification M 12, O 10

In New-Economy knowledge management plays a leading role in almost all areas of the economy such as development, manufacturing or marketing.

Relationships of knowledge bases (shape, carrier and availability) in a business capacity forms an important basis for action, a competitive advantage which leads indirectly to the success of the company on that market.

Promoting the knowledge society is not taking place only at the global level (eg Lisbon strategy) but also increasingly more micro level business and companies adopt knowledge management considering it as an indispensable element of the formulation of future strategies.

In strategic management, knowledge can be regarded as a specific management tool "Strategic Management" being a procedural perspective in literature.

"The basic concept is understanding the classic strategy developed under the Harvard strategic management tradition. Within this understanding of strategic management a

process that includes at least four distinct tasks or phases was conceived: scope definition phase (development of company policy, vision and strategic objectives), stage of strategic analysis (analysis of enterprise and environment and forecast future developments of information and ignorance), strategy formulation stage (forms, assessment and selection strategies) and the phase of implementing the strategy. The concept of knowledge management can be derived directly from basic procedural model of strategic management. Reference model shown in Figure 8, differentiate the functional knowledge management toward the methodological-instrumental. "

An overview of the possible constellations of knowledge-based strategy was developed by Albrecht (1993). Crystallized two double task of strategic management knowledge, formulating and implementing strategy, covering both the use and knowledge bases change.

This double character of knowledge has a direct influence on the relationship between conceptual knowledge of business strategy and range of its strategy. In the context of "Strategy Follows knowledge" the knowledge becomes a starting point ("enabler") in the formulation of the total enterprise, competition or functional strategies. This influence could be demonstrated for example in formulating an entry or divestment strategy. In the context of "Follows knowledge strategy", on the other hand, demand knowledge gaps that derived from business and competitive strategy is the strategic management and knowledge center.

In other words, strategic management knowledge has a management function of the strategic management of the company.

Strategic Knowledge Management is integrated into strategic management and is derived from it. This action significantly influences dual strategy in the spectrum of knowledge-based company's strategy, which

is characterized by an exchange of liaison "Follows knowledge strategy" and "Follows knowledge strategy. " There is a strategic synergy, where knowledge management and strategic management complement each other.

The purpose of knowledge management as a prerequisite for potential existing knowledge, knowledge tends to a corporate, integrated. This knowledge is an efficient processing of knowledge to achieve the main goals of the company. This organizational intelligence development in May and aims.

"By 'intelligent organization " means the ability of enterprises to cope with new challenges of structural changes within and outside the company. Other views are confined to an optimization of knowledge and a capacity increase of general learning to implement that knowledge in competitive avantejelor and goals of knowledge management. "

By optimizing the flow of knowledge is the ability to stimulate learning, as it can more easily identify and use knowledge. A high learning ability can lead to a corrected adapting to changing business environment, which ultimately lead to the building and expansion of competitive advantage.

Knowledge Management goal-oriented human capital refers to the process of learning and interacting individuals in the company's knowledge is not objective, but are obtained in the context, depending on the person. The purpose of the principle aims of the intellectual development of their employees.

Another area concerns the dynamics of knowledge bases of different media change the contents of knowledge. It can be seen as different processes of knowledge change, depending on when it comes to personal sources of knowledge, materials or collective.

Organizational learning and learning organization are two concepts often confused

If knowledge processes, knowledge contained change occurs through the process of learning and dezvoltare. By learning to understand, in this context, an increase of possibilities of action of various sources of personal knowledge.

On the other hand, signifies a lesser development of conscious and / or intentionally, and forgetting a step backwards

rather unconsciously and / or unintentionally the means of action.

In this context it should be stressed that learning should not always strive consciously acts nor necessarily in the form of observable behavioral changes or positive effects (eg increased effectiveness).

Detail changes differentiate various types of knowledge which can be explained by different theories of learning. Next, we can identify various situations in practice and learning with a multitude of factors that influence learning success. These are discussed below in more detail.

Individual learning produces a change in knowledge gained. Thus, the assimilation of new knowledge and the changing of existing knowledge can be distinguished two poles of knowledge change, which may rank among the various learning processes.

An assimilation of new knowledge exists when the person has as a result of learning-knowledge that until then had not. This may result from both cognitive training in November and a knowledge of possession of new skills or abilities.

On the other hand, there is rather a change in existing knowledge, where knowledge of depth at least in principle already exists. This type of change of knowledge is expressed among others by becoming more clear that cognitive contexts and connections are drawn between every fact in hand, which was not previously known. Further it is also about practice competencies and skills to be mastered at the end with greater certainty.

Deepening of existing knowledge could lead such a party to the internalization of explicit knowledge, if such steps are psychomotor unconscious. Here is the advantage of implicit knowledge requires less cognitive resources for activities related to perception and coordinative. It may result from an "explanation" of knowledge, if such actions carried out or measures taken unconscious to unconscious when they are consciously articulated. This explanation is often necessary to transmit knowledge and knowledge of others or store the media.

In psychology there are many different theories of knowledge which can not be discussed fully in the exposure. Therefore, we still have only a general summary of key research directions for the analysis of learning processes. In practice it usually

starts from a different set of learning processes.

According to Ke and Wei (2007), organizational culture is a social glue that allows individuals to learn together in social networks.

Independent individual learning processes: instincts and maturity

The creatures found possible processes that produce changes in behavior but not a learning process. Includes external influences besides first instincts and maturation processes.

Types of behavior are instincts and reactions to certain stimuli to some extent they become active only in certain situations. When people have a very minor role.

Maturation processes occur both physically and soul and is in many cases a prerequisite for further learning processes. Thus, certain movements involves learning appropriate muscle maturation. And learning a language is linked to the appropriate maturation of certain cognitive structures. Observing the process of maturation is important, among other things, to recognize the right time for certain learning processes.

Behaviorist theories of learning

Many of the learning processes of an individual can be explained if it is independent of the phenomena inside the body (in the sense of shape in a sort of "black box") and instead of considering it primarily contexts of change observable behavior and relevant external conditions. This procedure is called a study-SR (Stimulus-Response Study). Essential knowledge in this field of research is explained by the direction of behaviorism.

An assessment in this context is classical conditioning. In this case, is repeated an unconditioned reflex that causes a specific reaction, coupled with a neutral stimulus. One can see that after a number of rehearsals, a neutral stimulus also causes a reaction similar to that caused by unconditioned reflex. This effect weakens over time, there is a so-called extinction.

Further study of behaviourism is instrumental conditioning and operant conditioning. As the foundation of behavioral change are identified here environmental reactions to various types of behavior of organisms in the form of positive or amplifiers negative. In detail, receiving a

reward or avoiding punishment leads to more frequent these types of behavior, while the deprivation of rewards or imposition of a sentence causes the opposite. A longer absence of amplifiers lead to extinction of behavior, in which case the effect of extinction occurs later, if the amplification took place at rather irregular intervals.

The category of behavioral theories of learning is also integrated with some restrictions and learning by trial and error. In this case a person tries some types of behavior required for the resolution of a problem. Types of behavior which is confirmed in some form (that entails is success) are still followed, while the types of behavior are reused without visible success.

Moreover, behavioral learning theories can explain the benefits of knowledge-based or action (eg, learning of specific series of movements) and knowledge based on knowledge (eg elimination of false meanings by denial). The cognitive level is in principle about knowledge through experience. Cognitive theories of knowledge

Some learning processes can not be explained only on external conditions but requires both a process of interpersonal observation. These cognitive theories of learning and research are called SOR (Stimulus-Organism-Response studies).

Individual learning takes place largely in the brain and the memory is reflected in each person. For this reason while trying to understand the neurobiological foundations for learning. An essential result of this research is to identify three different stages of memory, called ultra-term memory (UZG), short-term memory (KZG) and long-term memory (LZG) which in turn are subdivided into several sections . These steps of memorizing the contents of memory are characterized precisely by the different periods of storage, different forms of memory (among other form of electrical signals in the form of protein) and various transfers. On this three-stage construction of memory is explained that there are two basic types of forgetting: forgetting irrevocable on the one hand and non-memory, where the fundamental contents of conscious access to knowledge stored in long-term (that's only partially accessible through hypnosis) is not possible, on the other side.

Individual learning is often attributed, in cognitive theories of learning, constructing "cognitive maps" (cognitive maps), enabling individual orientation. On this basis, a knowledge of personal support is provided, based on prior knowledge of that environment and image, to imagine a specific situation in mind, and to draw conclusions from it about the consequences of possible actions and thus find alternatives to solve concrete. In this case new knowledge to "existing knowledge, cognitive maps are semi-tailored. Such a learning process need not be manifested in actions immediately noticeable.

The cognitive psychology of learning is discussed and so-called implicit learning, which is characterized by the fact that the benefit without intent to obtain knowledge and learning outcome can not be expressed by the individual words. At this point is obtained in detail the question of how implicit knowledge is an unsolved problem in extensive research.

Social theories of learning

Some learning processes can be explained only by existing and in some cases the cooperation of several individuals.

A key conclusion in this context refers to the fact that individuals can learn from observing the actions of third parties already. This effect is discussed under names such as learning through observation, learning by imitation, learning by identifying, learning by model, learning by example, etc.. For example, competencies and skills can be learned by copying examples. The condition for this is that such knowledge should be made known in a noticeable way. It is often the case series of moves. But how to proceed in solving problems in many cases can be learned through observation.

In principle distinguish four different situations of learning (and teaching), which possesses typical characteristics occur in various forms, linking different knowledge bases and are suitable for various learning materials. As shown in Fig. 3-27 is about learning in detail about courses, learning workshops, individual learning and learning by doing.

Learning Situations:

- learning courses
- learning in working groups
- Individual learning

• Learning by doing

Learning courses

On learning courses, usually a lecturer is in front of a large number of students and communicates material in a structured manner. Here it is usual auxiliary environments (Beamer, Overhead-Projekt, board, etc..). Interaction is possible through intermediaries questions or feedback questions, but often deals with only a small fraction of the total. In essence, learning takes place in this situation from person to person.

Typical shapes of classical learning courses are classes at school, lectures, presentations, conferences and public speeches. Using modern communication technologies of information makes it more possible to include more remote participants at the event.

The course is suitable for pure fact-based knowledge communication and understanding of the basic contexts. But is limited in principle to explicit knowledge communication.

Learning in working groups

The working group learning more students, usually from the same level in a group to solve problems. And this situation prevails learning personal communication of knowledge between knowledge bases.

Group work is suggested in many courses as a form of secondary learning. Furthermore, it is often chosen in the form of joint working groups to assimilate the material. In companies, group work appears in a variety of forms. Therefore it is becoming increasingly implemented as a form of organization in the production. Learning takes place in the group but also in so-called knowledge networks (intra-company), in which specialists in certain fields of knowledge exchange, and in this way develop and communicate knowledge. More recently group work can take place through electronic networks. Group learning is appropriate to obtain problem-solving skills and teamwork ability. This can be obtained as explicit knowledge and implicit knowledge.

Individual learning

In individual learning, individual deals with matters independently of a teacher. For the study of classical literature as a form of individual learning is a large number of aids

such as textbooks, works of reference and tutorials scheduled. Individual learning opportunities have expanded considerably by the use of computers. For areas of learning and growing use of related companies, are the newest offerings provide CBT or computer-assisted scenarios. In addition more use of individual learning networking is required, peripheral and autonomous learning which is considered more efficient.

The individual learning takes place predominantly on knowledge dissemination of knowledge on physical media for personal knowledge bases. This learning situation is important to clarify gaps in knowledge and adapt to various learning skills. Especially favors the formation of explicit knowledge.

Learning by doing

Learning by doing occurs when the student gain new knowledge through practical use, often without the explicit intention of learning. The basis for such learning processes are both imitation and trial-and-error processes. For example, using models and prototypes as well as the possibility of "testing" in laboratory studies or in the simulations may lead to increased special knowledge and practical skills and training as a potential experience. Learning by doing business as often occurs on the job training.

Through learning by doing a trend favored implicit knowledge is being made. It is strongly oriented towards skills and competences. Also, the use of knowledge is gradually diminished the danger of forgetfulness, which is expressed in particular by the loss of skills, "if they are not always trained, optimized, adapted, thorough." This should not be underestimated in its importance. The personal media knowledge is replaced by the use of certain media content knowledge, so when such decisions are routinely taken by expert systems or when works are made by machine precision it plays an important role. In certain situations, personal media miss the opportunity to use those skills in other contexts. Combining learning situations

In practice, various situations occur very rarely as isolated learning, often can be seen alternately. This is significant in the sense that different learning situations can be used various channels of learning, and communicate different content. For this

reason I suggested various learning situations combined especially on complex educational goals beyond - for example in education, study or training.

The problem of combining different learning situations regain important, in contrast to rising use of computers and computer networks in education. Essential opportunities to use computers enough to enrich courses (Enrichment) through a primary or collateral to complete takeover of the handling of knowledge (Total Teaching). Multitude of learning situations is usually ensured by the fact that traditional forms of teaching are complemented by computer-based programs. The programs are basically designed as a computer-assisted, include (or simulated) usually several learning situations (for instance by suggesting support of a tutor, virtual discussion forums, virtual libraries, etc..).

For collective knowledge holders, as for personal media, we can speak of learning processes and unteaching respectively oblivion. This again defines different types of knowledge changes and different learning processes. Overall we can establish that collective learning has had less attention in research than individual learning.

Collective knowledge is characterized by the fact that the media is based not on personal or isolated, but on combined knowledge of media. In contrast to active learning and cooperative group, which stands isolated increasing their individual status within the exchange processes, collective learning takes place when common knowledge is changing and with it also the possibility of action and gender of the whole collective knowledge bases . In detail, the change can differentiate various types of knowledge.

Thus, knowledge of each substrate can be divided in collective media and thus become collective knowledge. Examples are the development of cognitive maps and the exchange of expertise. Collective knowledge can also mean that the interaction of knowledge in media collective knowledge arises entirely new knowledge, which before has not mastered this form of any one participant.

Ultimately, it can change, collective learning processes explaining the degree of common knowledge. On the one hand an

explanation of implicit knowledge before the support is born as a collective awareness of common knowledge can be articulated. On the other hand it can take place in earlier involvement of explicit knowledge. An example is "automate" certain routines. A possible consequence of such involvement is dissension among the various mitigation activities.

Types of knowledge described the change explained by various mechanisms of collective learning. Part of the learning takes place during the conduct of business processes.

Internalisation know-how usually occurs during unplanned constant use of knowledge. On the other hand knowledge outsourcing often involves a specific exchange and specific manifestation of that knowledge. In this context, a support group can develop knowledge and metacognition on ongoing processes and use this knowledge in future actions.

The formation of entirely new knowledge is more know-how, especially when sites supporting each of the knowledge are combined with each other in new ways. Processes relevant in this context are for example training for associations. These profound effects are analyzed in terms of creativity and are made available under various creative techniques.

In analyzing the collective learning processes should be considered that in particular groups, in many cases, have their own dynamics. Thus, it was determined that the groups can identify a clear tendency toward conformity (Groupthink). In the same time, groups have a greater inclination to risk that person singular.

Depending on the prevailing collective learning process, such as the composition of the media's collective, knowledge acquires a different meaning. While the creative process can influence the excellent performance of each shared positive result, the intensity of learning processes often depends on the jointly performance of one of the members of the collective knowledge support.

The changes to the contents of various media available knowledge changes in a company knowledge. In principle personal and collective learning processes can be distinguished as well as changes in media materials knowledge, where individual

learning processes acquires a special significance.

Changes of the contents of existing knowledge on the media make actions easier for a company, and are often more effective than changes in the availability of media to adapt to environmental changes and to make these changes in the possibilities of action.

Conclusions

Creative capacity of the human mind is immense, with a very ambitious importance and value.

An economy, or a modern organization can not sit side to knowledge management context because it is dynamic, competence, creativity and innovation, this thinking is not only aware of the Lisbon Strategy, but all participants the economy are in a continuous learning process.

To create synergies, trough which efficiency should increase and which could have an important role in the vision should be, in my opinion, human capital, which also contributes to the same extent to fulfill the vision.

In this way transparency on one part of the knowledge base and consistent care knowledge are guaranteed.

Employee motivation, sharing their knowledge by creating a dynamic market positioning, makes each area of business to be interested in increasing its market value trough its own employees.

Finally attention is acting both as a consultancy and as a raw material produced in equal measure.

One of the main points about knowledge management strategy, as already mentioned above, places Human Capital at the center of attention as a crucial factor for the company.

That is why the company does not give up any form of Spinne-off strategy in collaboration with universities, to gain potential future employees, young people with appropriate training and consulting skills.

Knowledge Management. Synergy between Theory and Practice

Crăciun Bucur Matei
Academy of Economic Studies, Bucharest
mbc@mmsynergy.ro

Abstract

There are, however, not much time, work to provide the reader synergies between theory and practice. The objective of this paper is to bring them closer to the reader the foundation and direction of knowledge management and aspects of it, because later this knowledge to develop the example of Best Practice and to be enhanced. It consists of two models of strategies in relation to the implementation of knowledge management, with special traits, oriented consultancy. The economic areas and the current scientific use increasingly more lately knowledge and knowledge management theme.

Key words: knowledge management, implementation, consulting, economy

J.E.L. classification: M 12, O 10

1. Introduction

In recent years many works on knowledge management have been written. However, they differ with the more basic character, the critics founding a number of adjectives and attributes by which to categorize them: from too pragmatic, not relevant from a practical perspective, inconsistent and based only on theories, up to unstructured.

Knowledge management is a main part of today's economy (see also "Lisbon Strategy"), upon the request of expressive description reflects the globalization of science, learning and the relentless flow of information. Global requirements, general economic and business world are subject to rapid change. In such stormy conditions, strategic management must pro-actively intervene.

The economic areas and the current scientific use increasingly more knowledge

and knowledge management theme. There's a real boom.

Knowledge gains a central significance for competitive success through focused knowledge management. A long survival in the competition can only stand as passing knowledge management as one of the key strategic features of the company. An optimistic interpretation is similar to Anglo-American in space: "In an economy the only certainty is under Uncertainty, the one source of lasting competitive Advantage is knowledge" (Nonaka 1991, p. 96), and expressed further: "the ability to learn faster than your competitors may be the only sustainable competitive advantage" (DeGeus 1988, p. 71). Birth and transformation of knowledge are at the forefront of business, especially for companies operating in knowledge intensive areas, such as consulting, software, financial services or biotechnology. To accelerate the spread of knowledge, the foundation and development of modern information and communication technologies are seen as key components that lead indirectly to new forms of transparent information.

Knowledge and intelligence are interdependent, one without the other losing its effectiveness.

Available knowledge slips through the various business processes and finally converted into business results.

Knowledge, unlike information, is creating a context, because patterns are dynamic, evolving over time.

2. The concept of knowledge

The term "knowledge" hasn't a common understanding yet, universally recognized, although in many areas it is a basic term.

For this reason, even in science there is a delineation of the term, which starts from the basic meaning.

Knowledge, viewed from a resource perspective, consists of knowledge, information and skills used consciously, or unconsciously by an individual or a group, in the use companies.

Andriessen (2006, 2007), Andriessen and Boom (2007) in the analysis shows that the prevailing Western thinking is the metaphor of knowledge as objects that can be created, stored, located, moved, controlled and manipulated. These attributes were associated with both individual knowledge and the organizational resources to deepen their knowledge functionality.

"Intelligence individual receiving dozens of definitions, knowledge also has a number of interpretations in terms of the definitions.

Building knowledge based on work experience gained over the years, no longer meets all the requirements, since it would take too long.

In Romania, there are many companies that use knowledge gaps in existing knowledge and are aware that it is necessary to introduce new methods and tools for use and usefulness of knowledge. Unfortunately, in practice, this happens rather hesitantly.

Knowledge characteristics:

- Knowledge includes information you provide to solve problems;
- Knowledge includes both knowledge and skills;
- Knowledge includes both custom items and non-customized items;
- Knowledge can be unconscious and conscious;
- Knowledge of learning occurs as a result.

The significance of knowledge has won a more relevant increasing role over the last decades in organization processes. It is therefore of crucial importance to both "human capital" and "knowledge" (related to learning and knowledge flows) to be accepted as the main component of any economic strategy.

Usefulness of collective intelligence in such cases is to create a new relationship, which can sort out the existing ones, resulting in a significant benefit for both individual and group to which it belongs.

3. Types and sources of knowledge

There are a lot of subdivisions of knowledge of which are mentioned four basic types of knowledge:

a. Knowledge of Knowledge. This arises from the perception of reality. It can be so subjective, the individual perception and objective - for example knowledge of mathematics;

b. Knowledge-based action - where abilities and skills count. It is influenced by natural abilities, but also by mastering problems or creative skills;

c. Explicit knowledge - knowledge is conscious, articulate, convertible into words. It can be transmitted between individuals, oral or written. Some examples of this genre would be:

- Database systems;
- Warehouse Data System;
- Expert System (Business Intelligence).

d. Knowledge of implicit (tacit knowledge) - is a state rather intuitive, unconscious knowledge, often obtained through physical experiences. "I see human knowledge in terms of the fact that we know more than we say. " The experience-based learning processes, implicit knowledge is developed through extensive accumulation over a period of time and linked to a particular context (eg task or activity). From this point of view, implicit knowledge deals with these characteristics.

e. Through interacting with the implicit knowledge explicit, the so-called spiral of knowledge creation takes part.

Stages:

1. First phase is socialization where implicit knowledge - implicit knowledge takes place.

Trough behavior or observation, individuals exchange knowledge. But that is not covered and transferred to explicit knowledge, and therefore can be used for the group.

2. This is about outsourcing, implicit-explicit interaction.

This is about the transfer (transformation) knowledge implicit knowledge explicit so it can be used for the group and transformed into an exploitable knowledge. The claim arises from dialogue and communication outsourcing.

3. Resulting combination of explicit-implicit interaction.

Here arises explicit knowledge, by concentrating, or combining existing knowledge processing.

4. The internalization (explicit-implicit) can be assimilated and passed on explicit knowledge group. Here, creativity is the main role.

"In a review of Nonaka / Takeuchi (1995) is notable that there are few data points for the explanation of practicable size. So to use the maximum size transparency, explaining that knowledge can not necessarily be motivating. For every explanation requires resources, efficiency is crucial issue in the decision. (Wiegand 1996, p. 169). Advantage explanation is, moreover, accompanied by a minimum of specialization of each member organization. (Weber / Schaefer 1999). The additional cost of existing latent knowledge explaining thus apply only to those parts of the knowledge base from which a contribution is expected from the company's strategic positioning."

To apply the knowledge spiral (Nonaka / Takeuchi), the following criteria must be taken into account:

- Trough vision and mission strategy, employees are required to generate knowledge. I take into account factors such as cost, efficiency and learning;

- Independence work serves as the strongest motivator, leading to the creation of new knowledge. Each individual is integrated almost throughout. Here it is a flexible type of communication of knowledge, from individuals to team up to design level, is the opposite of classic information flow. The project team actually plays the central role, in this place so-called platform collaboration, communication, exchange of information and knowledge;

- A third criterion refers to the fluctuations that can act as a vector for the generation of knowledge. Fluctuations can be generated artificially, but often arise naturally. Sometimes trough fluctuations the companies are forced to adapt to different demands or market conditions and this automatically leads to the generation of knowledge.

Knowledge creation results from the combination of tasks or duties intersection (implicit knowledge exchange). Under this

system, the diversity and variety of companies are born knowing. In this case, everyone in the organization has access to the necessary information and such combinations are formed, leading indirectly to refresh the stock of knowledge. Changes in organizational structure and conversion of staff (internal) allow employees to have access to new knowledge. An integrator is a field of forces Powerful Two or More Capable of combining elements into a new entity, based on Interdependence and Synergy.

A second more extensive system, particularly in Anglo-American literature, was developed by Sackmann (1992). It develops a typology of four distinct types of empirical knowledge in companies:

- "Dictionary knowledge, factual knowledge that answers the question "Why?" in a company. It represents the language acquired over time, cultural-specific, and defines a company.

- "Knowledge Directory" active knowledge that answers the question "how?" in a company. Is generally accepted as explanation for the cause-effect relationships and explains, for example, such problems that occur in organizations.

- "Recipe knowledge" and knowledge-prescription incorporate answers to the question "what must be done" to solve a particular problem. Contains regulatory measures and evaluation strategies for improvement.

- "Knowledge axiomatic" that knowledge principled answering the question "why?", being the basic acceptance of the current activities such as basic issues of strategic direction or future customer needs. "

Sackmann's basic idea - in 1992 - has been processed and înbunătătită by Krueger / Homp - 1997 - and of Bach / Homp - 1997. Sit authors three central categories of knowledge:

- "Know-how"
- "Know-what" and
- "Know-why"
- And recently, "Know-who"

in relation to each other and thus may appear different learning processes and synergies.

Know-how (operational knowledge) is used for both operational tasks to perform effectively and to ensure the ability to

compete. Original strategy to "Know-what-your piercing (strategic knowledge). It is characterized by a subjective perception and interpretation of reality. "Know-how" and "Know-what" Controlling knowledge are normative "know-why."

This kind of categorization shows centralized pluristratificate faces of cognitive object "knowledge" and explains that the concept of knowledge can be described in various ways in research and organizational practice observed. You still have to agree with Romhardt (1998) that this kind of collection of categories of knowledge is "at best, a first step towards a comprehensive understanding of knowledge in organizational contexts. Still open discussion about which categories may be subject to knowledge management and how the various categories of knowledge on each other.

Organizational intelligence, non-linear system, like individual intelligence, is not yet a unified approach.

Defining the boundaries of knowledge media

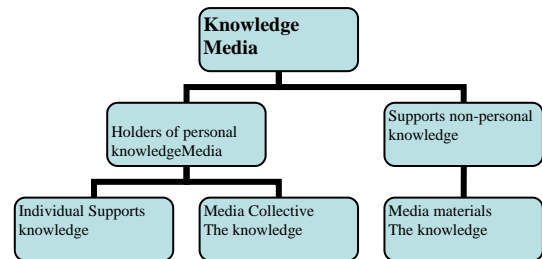

Within the support of knowledge are subsumed those physical environments in which knowledge can occur.

Knowledge is related to humans, however the information is stored in documents, databases or visual media. Rehaeuser / Kremar (1996, p. 16) go ahead with the delimitation of describing all the "objects, people or systems that are capable of storing knowledge" as knowledge support.

Due to multi-media knowledge, they should be divided into homogeneous groups. However, those works that have been processed, were reasonable and the contextual link can be described as knowledge stored documented (explicit).

The term "knowledge support" faced by individuals with a heterogeneous design knowledge about potential sources of organizational entities, business organization, network and all stakeholder.

Structuring the knowledge media

Source: Dr. Dr. Al-Laham, Andreas (2003). p. 35-36

Substrate materials have in common knowledge that largely meet the storage functions that at the same time are not capable of generating new knowledge.

Consequently, the quality of stored knowledge ultimately depends less support than on sources of knowledge.

Here is an excellent artificial intelligence in information and communication technologies in the sense that the combinations can be generated by new knowledge.

By separating the knowledge of personal media and data storage environments, different goals are pursued. Thus, knowledge is used for storage:

- Documentation of knowledge (ie, protocols)
- Preserving knowledge for subsequent steps of the process (eg data storage)
- Multiplicity of knowledge (eg publications),
- Opportunity to develop personal knowledge through other sources of knowledge (eg teaching materials, user guides)
- Knowledge protection of the rights (eg patents), and
- Guaranteed completion functions (eg knowledge of products).

4. Conclusions

One of the basic principles of a strategy refers to the introduction among the employees of the concept and behavior, according to which the exchange and application of knowledge is an effective approach, at both organizational and individual. This has implied a close link with the well-known slogans of strategy (strategic

concepts) by M. Porter: "doing the right things (efficiency) and"doing the right things (effectiveness).

The goal of stakeholders is to practice such a thought and at the same time to have common process knowledge. This requires an open and transparent atmosphere, while the exchange of ideas and knowledge are absolutely normal and not covered aroused any suspicion of physical or moral.

The importance and value of knowledge is enhanced on the basis of mutual exchange of ideas, which aims to create synergies. At the same time it is wanted to bring out tacit knowledge, which is much harder to identify than the classical one. Creative capacity of the human mind is immense, with a very ambitious importance and value.

From Economic Growth to Sustainable Development in a Globalized World

Crăciun Liliana

Academy of Economic Studies, Bucharest, Faculty of Economics

craciun_lili@yahoo.com

Abstract

Nowadays it is important that developing countries tap themselves fully to a new philosophy of development that is specific to the European Union and widely shared worldwide – namely the philosophy of transition from economic growth to sustainable development. Thus, concrete targets are now pursued, designed to enable transition within a reasonable and realistic time to the development model generating high added value, driven by interest for knowledge and innovation, oriented on continuous improvement of human life quality and of human relationships, in harmony with the natural environment.

Key words: Enhanced economic; economic growth; sustainable development; globalization of the world economy.

J.E.L. classification: F01; F43; F49; K00

1. Introduction

The issues of “economic growth” and “economic development” have been tackled by many macroeconomic studies and research in the past decades.

Potential economic growth materializes into a maximum growth rate of domestic production based on economic resources available at any given time and on the harnessing of available human and material resources.

Enhanced economic growth is a contemporary concept, which is specific to those developed economies planning to switch to ensuring in the dynamic the compatibility between direct economic efficiency criteria imposed by the market and the social – human and environmental efficiency criteria imposed by the constant need to create equal opportunities for existent

generations and for generations to come into being on the planet Earth.

The first concerns of the classics were clearly pointing to the economic growth issue. Thus, Lipsey and Crystal (2003) consider four important factors of economic growth: increase in labour force, as it occurs in times of population growth or of increase in participation rate; investment in human capital such as in formal education and on-the-job training; investment in physical capital such as factories, machinery, transport and communication facilities; technological changes caused by innovations introducing new products, new ways of manufacturing existing products and new forms of business organization and appropriate institutional environment.

Consequently, while economic growth may exist without sustainable development, sustainable development is impossible in the absence of economic growth.

The key element of sustainable development is the reconciliation between the development process and environment quality, the promotion of the integrated process of formulation and making decisions, both at global as well as at regional, national and local level. Sustainable development also depends on the fair distribution of the costs and the benefits of development amongst generations and nations. Sustainable development is based on the following key principles: concern for equity and fairness amongst countries and generations, long-term development vision, and systemic thinking – i.e. the intertwining between environment, economy and society.

Viewed at macro level, economic activities appear as an uninterrupted succession of growths, developments, stagnations and declines in processes and in their outcomes. The dynamics of macroeconomic flows has been approached and is currently analyzed using specific

concepts such as economic growth (positive, zero, negative) expansion and recession (depression); economic development and socio-economic underdevelopment; economic up and downturn; social reproduction (simple, enlarged, limited) etc.

The concept of sustainable development is based on the assertion that human civilization is a subsystem of the ecosphere, which depends on matter and energy flows within it, as well as on its stability and its self-adjustment ability. Public policies developed on this basis, such as the National Strategy for Sustainable Development, are aiming at restoring and maintaining a reasonable balance in the long run between economic development and the integrity of the natural environment, in ways that are understood and agreed by society.

The major objectives of sustainable development of any community focus on protecting the environment, eradicating poverty, improving life quality and developing and maintaining an effective and viable local economy.

Globalization overturns the old precepts of an economic, political and social nature, which have been governing the world for decades on end. Economic crises of the last decade of the XX-th century are the best proof that development systems should be redesigned and reoriented towards new trends.

The process of globalization of the world economy begun in mid 80s and has acquired new meanings and followers in the '90s and continues to manifest itself to our days, in spite of many regionalist and nationalist mentalities defying it.

The mystery of globalization can be unraveled through deeper knowledge of the phenomenon, its manifestation and its underlying causes.

Globalization has become the expression of a system that integrates itself to the utmost possible degree while remaining constantly open to integration, revealing its intentions in a more and more obvious way.

Exclusion from the system is exceptional and the entry into it is liberalized in as much as the system as a whole is designed to absorb extreme variations, including failures, even where the option belongs to one of its component parts.

In terms of human development, globalization covers not only trade, financial and capital markets, but also all that is fundamental to people and their life: technology, environment, culture etc.

As a strategy, globalization is the direct, verifiable and substantiated expression of rationality and judgment. Globalization is, in fact, an ideal world where truth meets freedom and justice amid a global generation of wealth and prosperity that is individually assumed, a world which is not necessarily the best world ever, but only one possible world that has been long masterminded by the human race.

Global ideas, global markets, global technology and global solidarity can enrich the lives of people from everywhere in the world, but they may just as well impoverish them at the same time. The key features of globalization are: contraction of space and time, disappearance of borders, and emergence of new markets, new rules, new players and new facilities. To promote globalization from a human perspective means to ensure that its benefits are distributed on a fair basis and that the growing interdependence amongst economies worldwide is working for the people and not for profit only.

Globalization has made communication easier for more and more regions of the world, connecting them to the economic and social reality of the Western countries.

The benefits of globalization are countless and are felt all around the globe and in all areas of activity, with major influences not only on the less developed or the developing countries, but also on the developed economies.

But, like any phenomenon, in addition to positive effects, globalization has brought a series of negative effects, too. Today, as a result of increased interdependence ties, it becomes more and more obvious that the world is gradually turning into one single societal system, affecting every one of us.

The foreseeable global system is not just an environment where private companies exist and evolve as distinct systems. It is a system that turns, through its social, economic and political ties, through its common institutionalized forms and through its communications systems that cross the borders between countries, into a totally new

system, which tends to substantially limit the action of subsequent systems, thereby determining in a decisive way the fate of the inhabitants of each such subsystem.

Moreover, we may anticipate the birth of a common consciousness with regard to globalization, the planet we inhabit and maybe, why not, to the planetary system as a whole and to the problems of the worlds that are about to find themselves. With the globalization phenomenon, we, humans, have discovered that the planet we live on is the one and only we have. Now all we can say is that we are all one big human family and that we must overcome all national, linguistic, cultural, racial and religious barriers amongst us. Globalization has, by its nature, a human dimension, as the world, seen as whole, as mankind, requires, in addition to involvement of the society, the involvement of each individual destiny and of the human species in its entirety. Globalization decreases the feeling of loneliness, isolation and exclusion.

Judged from this worldwide perspective, globalization transcends appearances; it looks at everything from a global scale perspective, starting from essence, substance, purpose, means and finality and seeking answers to the challenges we are faced with by the projection of our common future together.

Transition from bi- and trilateral treaties to regional and global treaties, laws and legal institutions, regional / global case law and doctrine, and from what is today a regional Fundamental Law to the "tomorrow's" global Constitution - is also a major challenge that is likely to change attitudes, mindsets and structures. Thus, we will gradually reach to new common global governance, which, within a given framework, will determine the internal (national) governance as result of increased application of the principle of subsidiarity in as many different fields as possible.

Globalization as a process implies a continuous movement as a source of progress and growth, coupled with dual identity of states and individuals (nationality). It requires an education that goes beyond the requirements of the specific national background, an education that takes into account the corresponding values socially validated regionally and globally, such as: cultural pluralism and interculturality,

freedom, equality, solidarity, democracy and the rule of law, alterality, free market etc.

Globalization is a process that expands the determinant framework of social change at the level of the world as a whole. It is an integrative process, touching many sides of knowledge; at the same time, globalization is syncretic, having a unitary character (unity in diversity). Thus, while social change has initially been approached within a local and national context, concern for globalization has increased the interest in explaining the relationships between territorial units and the world as a whole, with debates dealing with issues related to local – global rapport and to multilevel analyses.

Potentially, we are approaching the point where the world as a whole will find itself in each and every subsystem, while, at the same time, each subsystem, locality, region or nation-state will find itself reflected anywhere in the world as a whole. Each component deindividualizes itself, becoming more and more alike the whole, while the whole manifests itself more and more at the level of its components, with local conflicts turning into global social problems.

2. Conclusions

Globalization has opened the so called "book of the world", in which mankind can now write perhaps the most interesting episode of its entire life. Globalization appears to be, therefore, amongst the most important social changes the today's world is facing. Many of the today's fundamental issues, such protecting natural environment, avoiding military world conflagration or fighting terrorism are of global importance.

The study of globalization has a fundamental research nature because it implies a comprehensive and multidisciplinary investigation into human nature and society, in the attempt to resolve at global scale vital problems dealing with the conservation and sustainable development of our planet.

Even if the benefits of globalization have in many instances been small, the price paid was much higher, with social costs being, in some cases, huge, with natural environment heavily polluted and the pace of change much too quick to allow economies to adapt themselves to the new system of values.

But, fortunately, there are successes in the process, too, which entitle us to remain optimistic about the proper functioning of the globalization.

Abstract

Given the fact that during the last decade of the 20th century, thanks to Peter Drucker's works, a new concept (firstly in the USA and then on the entire world) has risen, the concept of knowledge-based economy or knowledge economy, a concept that is acknowledged as a new step in the information era, or the informational society, we considered analyzing its influence on the management accounting practices to be useful.

In the first part we will try to answer as much as possible to questions that have risen in time: what is knowledge-based economy? Is it the new economy's invention or was knowledge a key element right from the beginning of the industrial age? Which are its main characteristics? In the second part we will review the impact the new age of knowledge has on the management accounting.

Key words: knowledge, management accounting, convergence

J.E.L. classification: M41, M20

1. Introduction

The economic globalization, thanks to the speedy development of information and communication technologies, has managed to change existing socio-economic patterns.

The development of the knowledge-based economy and the worldwide spreading of the internet are two of the signs of the step made from the speculative economy to a new form, based on cooperation and democratic economy. Free software, open-source programs, electronic encyclopedias, blogs and other new media are just the first steps in revolutionizing the scientific, technological

and communication fields.

The economic theory and science acknowledge a particular kind of knowledge, through which characteristics of unprocessed reality are transferred into abstract models, based on rational constructivism, mostly theoretical and on the mathematical demonstration of the correlations that describe the models.

Accounting, as a fundamental and applicative science based on numerical management techniques, acknowledges a particular model of objective knowing of reality, able to be demonstrated by means of mathematical calculus, verifiable by maintaining the measuring and appreciation unit of the abstract models and by certificating facts comparing them to the scriptic dimension of the researched complexity.

In a time when knowledge-based economy and information economy put an end to all theories that relied on *homo oeconomicus*, we consider that the international accounting regulatory institutions (IASB and FASB) should revise their concepts and take into consideration that society needs real, pertinent reporting, which is mostly supplied by management accounting and not brought to the interested stakeholders.

As new products creators are becoming more careful to consumer needs, so do accountants need to follow the providing of information to comply to demand coming from different users. If contrary, reliance in methods used and even in accountants' professional skills may suffer.

2. About knowledge, knowing and the new economy

When it comes to information technology and communication, capital networks, knowledge-based society, different realities

are being referred to, often misused and wrongly mixed between each other. When it comes to knowing, training, competencies or knowledge, concepts that can be synonymous or different may be referred to.

The starting point is the fact that after a quarter - of - a - century - crisis of the taylorist - fordist - keynesian paradigm and a series of studies and analysis on the new forms of production and social organization, it is possible that, in the northern capitalist countries, a new paradigm of capitalist production, that we shall name "cognitive capitalism", has emerged.

Wealth production is no longer based exclusively on physical production, but on non-physical evidence, non-tangible "commodities", which are hard to measure and count, that come right from the use of power and emotional relations and of the human mind. It no longer relies on a standardized and uniform model of work organization, no matter the product type. Production takes place in different organizational models, marked by a network structure and the development of linguistic communication and transportation technologies. Therefore, one of the classic forms of unilateral hierarchical production organization is replaced by hierarchical structures stretched upon the subcontracting, production chains.

Work performance will change both in terms of quality as of quantity. In what concerns the work conditions (the quantity aspect), there will be a raise in working time, combinations of tasks will be possible, and working time and lifetime will go separate, making it possible for work relations to be individualized. As a consequence, work will attract more non tangible elements.

Today knowledge is a key production factor, especially in areas where technological, financial and organization functions of the production are available. We live in a world where remote control through technology and language allow for rich countries to survey the production process thousands of kilometers away, allowing the same control level, inherent in a capitalist organization.

In the knowledge era a new international labor division is being developed by means of spatial knowledge and communication division. This will be the new international

division of the accumulation processes that stand for the dynamics of space at a global level.

The question that rises is: can knowledge (on the one side, the process of knowledge transmission, meaning education, and, on the other side, the process of knowledge - creation, or the starting of scientific research) be considered to be a commodity, like any other production factor?

We currently are aware that, from the neo-liberal capitalists' view, it all becomes a product than can be associated to a positive valor (price). The more common a commodity is, the smaller its price will be. This explains the diversity in prices and income. The trade economy is in fact, for all products, a change in property, and the change in knowledge is in fact a change in emotions and life experiences. But knowledge is not necessarily fully separated from the human being. While work capacity is somehow separable and can be shared (especially at the work place), cognitive and activity knowledge are a part of the human being. Is it possible for the exchange to involve the transfer of property rights? Evidently, no, because each transmission (exchange) of knowledge led to the efficient diffuse of them to a larger area of people. In other words, information and knowledge exchange does not mean the alienation of the assets sold by the seller, like all merchandise and services, for a certain price. Knowledge is not limited, it can never be bounded merchandise, and it generates cumulative knowledge and it become more abundant as time goes by. Strangely, the more we consume more information and knowledge, instead of diminishing themselves, they tend to disperse themselves and become more abundant. From this point of view, according to the classical liberal theory, the price for knowledge should be equal to zero. This doesn't mean that in a purely capitalist view property rights on knowledge should not exist.

Therefore we can agree that the essentials of knowledge are:

- its capitalization is commonly based on dues and not on the selling / buying;
- knowledge does not consume, but on the contrary, the more people access it, the bigger its positive effects (the

- so called "network effect");
- knowledge creation is favored by the strict defense of the rights to access it, and the contrary phenomenon of "piracy" of this access has a negative and non-simulative effect.

As a conclusion, knowledge cannot be a commodity, in the capitalist meaning, and therefore, there is no private market, where property rights can be exerted, except when they are considered on-the-spot interventions (patent, copyright, exclusive rights etc.). As a consequence, knowledge is a common commodity, in the sense that it is the collective result of interaction of the human and social development.

Knowledge based economy may seem to be an "invention" or a late "discovery in the last period, a myth built around information (knowledge coded to be processed by a machine). On the contrary, it's much more, it is a natural, inevitable change. Once the limits for information established, the process of evolution from information to knowledge doesn't seem as simple as first seen. From the moment in which knowledge based economy confronted a more and more complex environment in which there had to be continuously developed new knowledge in order to ensure real predictions, it has been proven that not only the coded, useful only to computers and machines information was sufficient, but also human intervention and typical learning, too.

Defining knowledge based economy is a difficult task, taking into consideration the great variety of implementation made to the concept and the specifics of the countries that have envisaged significant progress. The academic literature offers two defining directions:

- from the euro-american point of view, which emphasizes explicit knowing, by means of words or numbers, scientific formulas, manuals, universal principles;
- from the Asian point of view that emphasizes tacit knowing, based on impressions, intuitions, inspiration, flair, values, faith, ideals, emotions, perceptions and ways of thinking.

Mihai Drăgănescu, chairman of the information technology section, at Romanian Academy, defines a series of vectors assigned to the knowledge based economy,

spreading them into technological and functional vectors. Among the technological vectors: the internet, the e-book, artificial intelligence, nanoelectronics, and among the functional ones: knowledge management, e-business.

3. The effects of knowledge-based economy on management accounting

In this knowledge-based economy, there will be complex mutations. Electronic communications will be used as platforms for political, social and cultural activities. The internet will become a proper environment for one to express its ideas on the world, life and society. E-commerce is supposed to become a pillar of the new economy.

Also, because of a shorter decision-making timeframe, an increasing number of companies will call for intelligent systems to assist management in taking important decisions by more often using a form or another of decision-assisting software.

Under these circumstances, we can wonder: is management accounting an expression of globalization or localism?

Sheridan thinks that management accounting's practices in European countries converge towards a common model, which is the American one. In his book, Bhimani suggests that the "americanization" of the accounting techniques began when some of the european countries started emphasizing on costs for planning and decision making in the 1960s and continued with the "new" administration accounting promoted by Cooper and Kaplan at the beginning of the 80s. Also on the ground of the "americanization" stood the attending of European university teachers and managers to US university courses starting from the 1960s.

As a consequence a demand is to come: do the European management accounting practices become part of the globalization process (Sheridan, 1995)? We are willing to believe that in a context where different societies from different parts of the world are confronting similar threats and opportunities, such as consumer typology, technological incertitude, accounting regulations, competition), differences in what concern organizational design, processes and

practices, including administration accounting will shorten. Globalization will also be encouraged by companies worldwide, which rely on a growing basis on the same consultancy firms and hire university graduates that studied similar management accounting techniques.

At an international level, in the academic environment, there is large consensus on the fact that management accounting systems show a global tendency towards convergence. The factors that lie beneath this convergence process are: transnational regulation, integrated markets, education and information technologies.

Starting from 2005, with the adaptation of the International Financial Reporting Standards (IFRS), due to extended requirements for annual reporting, management accounting has to provide a large amount of information, despite the fact that financial reporting is mainly done by the financial accounting. Therefore, cost evaluation procedures had to be adapted to comply with IFRS requirements, and in order to allow for a time comparison of the results, annual reporting of 2002-2005 had to be done again using the new methodology.

Following the adoption of IFRS, there were voices who said that, although these standards are an important step in the process of sustaining transparency and comparability of the companies from the investors' point of view, they failed in finding a common point between local standards and the local development of management accounting techniques. Furthermore, with the global increase in the demand for audited financial statements, managers and auditors felt the need for an internal accounting and a standardized control to support IFRS.

The influence of integrated markets on the convergence of management accounting can be separated into intrinsic and extrinsic factors. This way, global harmonization of management accounting following common practices of branches from different practices constitutes an intrinsic factor, whereas among extrinsic factors we can find the growing competition which comes with measures being taken to improve efficiency, but also changes in the capital markets. In Europe the accent was on the company's interest but, with the coming of American and British investors on the European markets,

shareholder value management began gaining interest.

Researchers in the academic field are the third convergence factor. Pistoni and Zoni (2000) found that, through alumni exchange, and by large-scale use of American study books, management accounting education tends to converge to a common model. Therefore, at an international level, courses tend to cover similar topics.

The larger distribution of similar information technologies can be another convergence factor. IT is today a critical resource for every company competing in the global economy of a digital era. Depending on the industry, market and objectives IT can allow access for a large scale of competitive strategies. Furthermore, it has become an essential infrastructure for every company, the backbone for the flow of corporate information and a business driver (Huang C.D., Hu Q. 2007).

On the background of the progresses in information processing technologies, we are currently undergoing a functional integration between financial and management accounting in the sense that a single entry goes into a global data base, which will provide the base for elaborating both financial statements for the financial accounting, but also for the cost analysis common to the management accounting.

Increasing competition in all areas of activity, as a direct effect of globalization, has resulted in an international competition for the best model for the application of corporate governance principles. Each country developed its own management system depending on the economic, political and cultural heritage, and this hampers the work of the big corporation.

Structural differences between American and European systems are essentially related to the influence exerted by the way of which external financing of corporations is done. Therefore, the U.S. has a strong shareholder oriented legislation so that everyone can have an influence on the company as long as you buy its shares. Even more, because speculative funds invest a great deal of money in the stock and bond markets, even those who do not own private shares have a direct interest in the health status of the corporation. In this model of governance, capital market oriented, implemented in

countries like Great Britain and the U.S., individuals invest their savings by purchasing shares. The corporate financing is predominantly in the capital market.

Instead, the situation in Europe is slightly different. European companies increase their capital through retained earnings or banking systems. The legislation protects investors rise and fall of stock markets and bonds, but also eliminates, most aspects of the corporate world. In European model, the external financing of corporations is through banking institutions. Banks play an important role in financial markets and sell a product line significantly more varied than traditional credit institutions.

Unlike financial institutions operating in the U.S. and UK, those working in Europe have access to information enabling them to monitor and, if necessary, to discipline companies management. In addition to the fact that credit institutions have direct influence on the companies they finance, these management systems are characterized by the following:

- making frequent checks and audits within corporations that fund them (Insider System);
- banks supervise the companies through shares they hold, their aim being the recovery of borrowed funds and not profit maximization, which gives to tension between the majority and minority shareholders;
- employees are actively involved in the audit.

In these conditions management accounting may lose because of the influence of interest groups (eg shareholders) that are privileged and may obtain informal and private informations.

4. Conclusions

Although prof. Nicolae Feleaga mentioned in his book that *management accounting cannot, in any way, be a one-scenario model and furthermore, it cannot be normative*, we consider that the new economic environment in which management accountants work will influence their practice. Even though there will be different decision support models and techniques depending on each country's economic characteristics, the global tendency is to level the accounting practices, hereby

including management accounting, too.

The changes in the business environment and the technologies used by the companies in their daily activity could produce essential changes at the level of management accountancy. Thus, these changes lead to new decisions and to new problems related to management accounting practices.

Marketing Strategies in Tourism

Cristea Doina

"Tomis" University of Constanta

cristea_doina2004@yahoo.com

Abstract

The determining element in developing the Romanian tourism is represented by the definition of a realistic conception concerning the capitalization of the touristic potential and the objectives of its development, taking into account the international tendencies, mostly the European ones, regarding the travelling options and the ways of spending holidays requested by the foreign tourists as well as the local ones. In Romania, tourism is also considered an export industry, generating exchanges and creating jobs. The tourism industry is quite different from other export industries through the fact that the potential of a client comes to Romania for the product, and the product is not sent back into the client's country, like it happens in other industries. The evaluation of the touristic industry in Romania indicates the fact that tourism is one of our export industries, effectively competing to other countries. There are, anyway, some problems regarding the standards of the product and of the services, the marketing and the publicity, the culture, the environment, the organization and the legislation, that should be overcome in order to realize the potential.

Key words: agency, tourism, marketing

J.E.L. classification: M31

The notion of touristic product is generically defined as being a mixture of goods and services necessary to stimulate the specific consuming touristic activities.

S.C ITALICA S.R.L CONSTANTZA is a touristic agency with Tourism License, category A and Tourism certificate in 2003. The strong point of the agency is constituted by the relations that the manager and the owner of the business at the same time has with different touristic agencies from the country and from West Europe. The business

itself was conceived as a plan resulting from the analysis of several possible variants.

The activity scheme:

- an operating turn in the internal and external tourism
- commercializing programs and adequate touristic activities towards the tourists
- booking and commercializing accommodation services, transport, touristic assistance (guides, interpreters)

The starting point in elaborating this plan was represented by the establishing of the activity objectives:

- products/new touristic services, superior in comparison with the ones offered by the competition
- ensuring the necessary funds to initiate and develop the business
- an intense activity to prospect the internal and external market
- promoting the brand widely on the market
- the permanence of the customers
- ensuring an adequate balance between quality of the services/the right price
- close relations between the internal and external touristic agents
- the improvement of the distributional and informational channels
- associating to an occidental partner from tourism, someone with market potential particularly with the products designed for the balneary tourism, association that contributes to the development of the economic competition of the products and the services offered by the agency, as well as to the distribution of the products/touristic services

One can state that the touristic product is absolutely perishable, determining the impossibility of storing it, it is hard to present it to the customer, being immaterial, hard to mark it and impossible to take it to

the customer, harsh to any quantifying and qualifying modifications of the demand, on a unstable market, quite difficult to model.

The touristic specific terminology uses two English terms, incoming (the organization and offer of touristic services to foreign citizens who choose Romania as their touristic destination) and outgoing (the reorganization and the offer of touristic services to the Romanian citizens travelling abroad).

The touristic products offered to the customers can be initiated either by the touristic agency or they can represent products of the great touristic agents that they have put in sale, with a commission, for the collaborating touristic agencies. These touristic products are meant to the organized touristic groups as well as to the individual tourists.

Achieving these objectives is closely related to the capitalization of the opportunities identified on the market. The first analyzed aspect refers to the age groups that the offer addresses to and to their financial possibilities.

➤ For the offers destined to the balneary tourism launched on the intern market, but mostly on the external one, the age group aimed to is that with medium and high wages, over 50, but also those who suffered some serious injuries and need balneary treatment.

➤ The agro-touristic offers, mostly during Christmas and Easter time addressed to the families living in the urban areas, but also for the Romanians from abroad

➤ The relaxing tourism for the great companies staff: promotes this kind of tourism within the organizations ruled by managers who know that resting leads to the rising of the efficiency of their staff

➤ Holidays are destined to all age groups, but fit into the average wages category

➤ Cruises are destined to that population group that has more spare time (over 50 years old) and whose income is quite high

➤ Ticketing is for the physical or legal persons that go travelling quite often and prefer a certain airline, but also for the Romanian and foreign staff of the great companies

➤ On-line booking

➤ Express services are auxiliary activities for the ticketing operations

➤ Touristic transport (charters, coaches)

All the products and the touristic services proposed by the agency have as basis an analysis of the market, the analysis also

representing the helping element to accomplish the proposed objectives. The analysis of the market realized researches regarding the customers, the competition and the opening market.

As far as those requiring touristic arrangements, the segmentation of the touristic market within the Dobrodja area determined that some possible clients might be physical or legal persons. Through analysing the market, it has been approved that the group regarding the ticketing operations is not sufficiently exploited by the competition, and the touristic agencies that concluded contracts with similar agencies out of the country go just for the classical touristic offers.

The research of the market proved that most of the touristic agencies from the seashore area rely on the classical balneary touristic offers (respectively Mangalia, Techirghiol, Baile Herculane, Baile Felix) without exploring other areas from Romania, offering good or even superior accommodation conditions (Bazna, Corund). According to the analysis, the touristic market registered a slower evolution, but certain for the balneary treatment offers and an ascending evolution towards the external touristic destinations (Egypt, Greece).

Another important group is represented by the requests for the rural tourism, the agency taking into consideration the internal market (the urban population) as well as the external market (the Romanians from abroad). The manager of the company also relies on the contracts with some Dobrodjean agencies that will offer to their employees, in certain conditions, an alternative to the everyday monotony, respectively a way of getting some rest. The agency will introduce among its offers some classical destinations, having as major objective attracting more and more customers, proving that it can represent a danger for the big touristic agencies.

The marketing policy stipulates, in the beginning, the adoption of a strategy focused upon a market group for every product, group that will be at its service and will know very well its needs.

Moreover, the manager of the agency will release as marketing policy and promotion the participation at the Touristic

Fairs organized by the Tourism Ministry, C.C.I.N.A. Constantza, A.N.A.T., A.N.T.R.E.C, the fairs having as goal knowing the tourism services operators and concluding advantageous contracts for both parts, as well as promoting touristic offers for the potential customers.

The business plan included a products and services developing plan, referring to the high prices practiced by the company in comparison with other touristic agencies' similar offers but, to their own research and development actions, for the next period of time. But for launching a product on the market, there should be taken into account several elements: the moment of the launching on the market, the target market, the place and the way its commercialization will be started. For touristic products, commercialization represents a complex problem due to the characteristics of the offered services, but its complexity is emphasized by the staff that facilitates selling the product and will have a deep mark on it.

The marketing plan starts from reducing the difference between production and consumerism, being an answer to the necessity of orienting the touristic products according to the actual needs and to the perspective of the market.

The marketing research will offer the necessary information for fundamenting the decisions of the managerial staff in formulating the programs, the plans and the market strategies, as well as the strategy of the entire agency and will include:

- the product policy
- the price policy
- the distribution policy
- the commercializing and promoting program of the products/touristic services

The correlation of the four variables (product, price, distribution, promotion) emphasizes the way for a practical realization of the market strategy. The feature of the mix marketing is given by the touristic market on which the agency is about to enlist.

The product policy: is the most important element of the marketing mix, the touristic products/services representing the main communication ways between agency and market. The agency searched particularly the market groups to which the services and the touristic products address to, as something new, but they did not neglect the touristic products from the offer list belonging to the

competition, here interfering the agency price policy that must lead to getting a high peak on the market and the loyalty of the customers. In order to thank the customers and to participate to the reaching of the established objectives, the agency must permanently develop new touristic products/services, to improve the existent ones and to eliminate the ones that would not satisfy the customers' needs or would not bring acceptable profits.

As far as the price policy is concerned, it will be followed the correlation between demand and offer on the local touristic market. The establishing of the price belonging to a product /touristic service is the result of the actions of a multitude of factors. The most important factor influencing the price is represented by the complex and heterogeneous nature of the offered touristic product, but also the quality of the touristic services depending upon the staff professionalism.

Taking into account the fact that every tourist learnt to compare the price with the touristic price and if this seems unfavourable as long as the quantity or the quality is concerned from a certain country or a certain resort, he will avoid requesting the destination offered for spending holidays. As far as the buying decision belonging to the tourist, the variable price can have a moderate, inexistent and loose influence. This means that, several times, the touristic consumerism is also determined by emotional, psychological factors.

The analysis determined that the seasonal touristic consumerism allows a strong rise of the prices according to the moment of consumerism (sometimes the difference can reach 20-25%). The establishing of the prices of the touristic products/services imposes taking into account not only the elements of costs, but other factors like demand, competition, but mostly the consumer economic potential. The raising of the tourist income represents his economic potential. Under this respect, we can distinguish a market of the luxury tourist, rather loose, made up from customers getting high income, hard to satisfy, asking for sophisticated touristic products at fluctuating levels; a market of the average tourist which gathers tourists

with average income, being customers quite easy to satisfy and the market of the mass tourist constituted from clients with average or even modest income products less elaborate and at low prices.

Creating a general image upon this business relying on the global diagnosis show that the strong points are concentrated upon the new services that can be offered, by unusual touristic services, sustained by the respective group that has never been exploited by the competition and the weak point refers to the low peak market for some products, but the possibilities of co-partnership and recruiting young people even from their freshman years represent opportunities that can lead to a rise of the peak market belonging to the agency activity. The weak financial motivation of the employees, the price risk (the existence of superior or inferior limit of the price in the opinion of every tourist), the flexibility of the competitors to adapt to the conditions of the market, but also their organizational process all representing possible risks for the agency.

The study of the market

The identification of the accessible market supposed the answer to some basic questions: What is the target market? What are the market dimensions? What is the activity of the competition? For instance, the ticketing operation relies on the cashings coming mainly from plan tickets booking for the foreign staff of the Nuclear Power plant from Cernavoda (fig. no.1). This operation supposes the collaboration with the airlines flying mainly towards Canada, Italy and India, taking into account the customers' preference, oriented towards certain airlines that flew with, but also the loyalty towards a certain airline (this loyalty supposes to have certain advantages). This market group hasn't been exploited by any other touristic agency; in conclusion, the competition does not exist upon the target market in question, beneficiary of this service.

Fig.no 1 The statistics of the staff department CNE Invest Cernavoda

For the balneary touristic services, the target market will be oriented towards the foreign tourists (the age group over 50), but will have an oriented limited group towards the intended tourists, too (the collaboration with the Tourism Ministry for selling social services for pensioners and students). The touristic offers for the external market existed permanently, but according to the statistics there have been fluctuations as far as the foreign tourists arrivals are concerned (no matter the used means of transport). This fact is due mainly to the treatment devices growing old, but also to the weak collaboration of the touristic agencies with the investors creating new treatment clinics, with extremely modern devices. In this respect, the touristic offer on the external market (Germany, Holland, Sweden) of the agency will include traditional destinations (Mangalia, Techirghiol) but also new destinations (Bazna, Corud). The internal market will also benefit of a series of attractive offers, offering certain facilities to the loyal clients (an extra day of treatment, feasts) but also some treatment tickets given through social insurance. The competition is sufficiently high for the traditional destinations, but it is inexistent for the new destinations. That's why the agency will be oriented towards the promotion abroad of these new offers. Another studied market group is the rural tourism, its offers being addressed to several categories of clients, mainly to the families from the urban area. We have noted that it is a form of tourism that can be taken into account on the internal market as well as on the external one (the Romanians

living abroad). The internal market is firstly oriented upon the customers from the great cities of the country, in our case Constantza. The citizens of Constantza want holidays in the mountains, in the rural areas as the seashore tourism is at their ease. In order to promote this kind of tourism, it is necessary a close collaboration with ANTREC (the National Association of the Cultural, Ecological and Rural Tourism). The association will offer the necessary commercial materials in order to attract customers, and the agency will conclude the offers. The areas preferred by the tourists are Alba, Brasov, Maramures, Sibiu, Suceava and Tulcea (fig. no.2).

The surveys realized by different institutes ordered by ANTREC proved that Christmas and Easter feasts represent peaks in the rural tourism, this being due to the inherited traditions across times and which were kept intact in some areas, the traditions being extremely convincing on the external market. The competition exists and it is strong enough for this kind of tourism, but the development of the rural tourism will create new locations, the most important being the way of promoting them in order to attract new customers. Moreover, an extreme importance must be given to eth accommodation conditions from these rural areas.

Fig. no. 2 The rural tourism
Source: The Statistics of ANTREC

Another touristic offer that the agency proposed to take into account concerns the relaxation tourism for the great companies' employees. This form of tourism can be applied only in the companies where the unions have an influence in taking decisions by the company management and of course, in companies where the manager thinks about his employees' future performances, offering them some adequate sources of relaxation that will have as a result more careful implications in the objectives of the company.

There were several groups taken into account, represented by the staff of the agency Oil Terminal Constantza, the staff from Carniprod Tulcea and the staff Lafarge Romcim Medgidia (a total of 8000 employees), agencies that established contacts, this type of tourism being offered even to other agencies belonging to other districts from the country. Initiating this type of tourism relied on the fact that there are certain discounts concerning the tourism assistants (hotels, restaurants, pensions) and the personnel will benefit from the conditions established in accordance with the touristic agency. In the Dobrodjean area, there is not competition for this type of tourism. In 2004, the manager of the agency negotiated with the respective agencies as 10% of the personnel to benefit from this program, the estimations for the next four years being step by step to be attracted up to 85% of the staff.

The thematic trips represent another type of tourism that the manger of the agency proposed to exploit, taking into account the fact that the touristic potential of the Danube delta is sufficiently attractive for any touristic market, internal or external. As far as the internal market is concerned, it had been aimed towards the general schools, high-schools but also faculties with a certain specialization, educational institutions that can require the organization of some special programs in order to exemplify courses (fig. no.3).

Fig. no 3 The Internal Market

The competition on this group is relatively reduced. In the case of amplifying it, there will be taken some measures to differentiate the offer. The agency is concerned with other products services where the competition won the trust of those customers interested in quality touristic services. In this respect, the manager of the agency must watch the predicted peak market. The balneary, summer, mountain offers as well as the external ones are on the list of touristic products of all the tourism agencies, the competition being defeated by a strategic price policy, this being also determined by the seasonal nature of the touristic expenditure. The analysis of the market took into account the demands on the external tourism, referring to the destinations chosen by the tourists from the area. The main destination for this tourism is considered to be Turkey and it will have to suffer in the next period due to the political instability as well as to the introduction of the visas in 2004, relying on the agreement between the governments of the two countries. In exchange, Greece and Egypt will remain Key-destinations for the Romanian tourists, Egypt being preferred during the Christmas feasts being known that during this time of the year, tourists prefer countries with an opposed climate than they have in their native countries. Nevertheless, Spain recorded noticeable reduction of the tourists' arrivals after the tragic events from 2004, March 11, and today, the measures to enter this country are more and more restrictive.

Fig. no. 4 the Peak Market of the Local Agencies

Taking into account the reduced number of tourists in the external area, it results a very high developing potential, and offering some touristic services for several income and preference categories can determine on short term attracting a great number of tourists in the external tourism.

Stages of Organizational Change

Cristea Doina

"Tomis" University of Constanta

cristea_doina2004@yahoo.com

Abstract

Knowing the change process in order domination, if possible, it represents a characteristic of an efficient management organization that can ensure competitiveness. An organization is even more efficient, more competitive, as has the ability to continuously develop on multiple levels. This explains the fact that literature is increasingly approaching the concept of organizational development.

Organizational Change is a process that, regardless of the applied field, will require scrolling, in general, the same steps to move the situation in which the organization finds a desired future situation.

Key words: management, change, organisation

J.E.L. classification: M10

The general implementation model of change, all works for the conception, design and implementation of changes can be grouped into the following stages:

- Triggering change;
- Motivating change;
- Creating a vision;
- Finding a supportive policy;
- Change management;
- Support the change.

1. Triggering Change

Triggering the process of change occurs when there are signs that the owners or managers of organizations to improve the overall activity, or occurrence of problems that could affect the development organization. These problems may be less obvious, such as those relating to product quality or less obvious, such as those relating to the reduction of innovative spirit.

Step triggering conditions change trains carrying other stages of change and development, highlighting the main concerns of future specialists in change.

If you choose to change the use of specialists inside and outside the organization, the work included in this stage are more complex, because the need to collect preliminary information to assist in defining problems.

Identify the parties involved in the process of change.

In the process of change, are generally involved two parts, one that supports change and one that conceives, designs and implements change. A party may change throughout the organization supports a collective work or a department within the organization, part to be identified with very high accuracy, because it must be involved in the process and one that will not be affected by the change. The other side is represented by those who conceive, design and implement change and may be represented, as mentioned before, the specialists in the organization, from outside or by a joint team composed of experts from inside and outside.

The parties must determine what conditions is cooperation possible, and if so, are necessary: identify organizational problems, setting the party representative of the organization to solve problems and choosing the most appropriate specialists in change.

Identifying problems referral organization refers to deviations from organizational goals, which would have negative consequences on the effectiveness of exhibition activities and the use of production factors.

This stage is of great importance because the accuracy depends on the development stages to identify problems ahead. This process of identifying problems is very difficult because some problems are harder to spot due to insufficient performance

management methods practiced in the organization.

Once identified the problems facing the organization, change and organizational development specialists will come to collect preliminary information on its achievements. This preliminary information will be made in a very short time, through interviews with representative compounds of the organization. The data collected are necessary to correctly determine the two parties in the process of change.

Establishing representative part of the organization to solve problems they encounter. The representative part consists of those members who are directly involved in the process of change and who will be consequential effects of change. Identifying those people most representative organization involved in the process of change is different in terms of complexity, depending on the nature and scope of the problems identified.

The choice of suitable specialists for the change process is another activity to be performed for the change. Selection specialists in change must be made by certain criteria and assessments such as the consultant's ability to establish interpersonal relationships, the power of concentration and consolidation of issues, ability to inform the client of the problems involved, membership in a professional specialist . In selecting specialists and change are important information obtained from other clients who have benefited from their respective specialists.

In conclusion specialist in change management and organizational development must not only be a person with specific knowledge, methods and techniques that have the appropriate change, but to also take a certain personality and ability to create and use interpersonal relationships. In terms of specialization, it must address a neutral position, to use scientific knowledge in several fields, to handle the various scientific theories.

The shrinking process of change.

Once problems are identified and established the necessary organizational change parties involved in this process, it is necessary to reach an understanding between them, understanding that most often manifests in a formal contract stipulating the terms and conditions of work. The

contracting process includes the necessary elements of the change process, and includes the following objectives: to expect each Contracting Party to change the time and resources to this process and general rules to be observed between the two sides.

Needs part refers to how each party participating in the process of formulating their expectations change. In other words the organization by those they represent, require services from specialists in change, and they can follow to obtain some gains.

Time and material resources, financial and human resources necessary for carrying out the process of change is dimensioned depending on the complexity of change, the scope, the difficulty of implementing change within the organization and the degree of training and awareness of the experts used in the organizational change and development.

The general rules that must be respected by the parties in the change process, including various specifications to confidentiality works, the relationships of authority between those involved in the process of change, the imposition of measures of improvement.

2. Reasons for change

Any change, no matter what level takes place within a certain organization, requires a shift from a certain known state to another state that involves some unknown resistance both from individuals, as taken from the organization as a amsamblu people. Management task in this case (see fig.3.1) lies in motivating staff to change, which requires preparation for change and overcoming resistance to change especially.

Preparing change must have as its starting point the fact that success depends on a change that people feel the need for change. It is possible that at some point people do not want change because it involves changing behavior and not always easily accepted. Preparation that causes discomfort that "thawing" and move towards a different state that is desired is made with some difficulty because people accept the change more difficult level of organization is organizational development. Generally people have to suffer enough before to change the behavior. This is accomplished by creating an entity-level dissatisfaction where

it wants to change, using several methods such as:

a. The organization's sensitivity to pressure for change is driven by some endogenous or exogenous causes, such as increasing competition and rapid changes in technology. Organisations must be sensitive to such factors to prevent losses and forced to adapt the organization to these pressures. You can avoid this practice if the organization will increase relationships with other companies in the country and abroad, through visits to companies that use performance standards to be achieved.

b. Highlighting the difference between actual and desired state, which shows the need for change. Desired state towards which it wants to strive, may contain the organization's objectives, standards covered, as well as an overview on the characteristics of the state you wish to arrive by the proposed changes and supported the organization's management.

c. Dissemination of positive expectations on change has an effect on staff motivation in its attempt to engage in change, the transformation of service. We know that if staff is confident of success, he will engage with all their energy to promoting change even if it is necessary to change behavior.

Overcoming resistance to change is justified because the staff may be anxious for the transition from something known to something unknown. Individuals are not confident that their work can be appreciated in the future as it was appreciated until the triggering change. In this case staff need to be useful to think of their work in new conditions imposed by the change.

There are several methods of overcoming resistance to change, namely:

a. Understanding and supporting those who resist change, for various reasons which sometimes remain unsolved, can bring a plus in reducing resistance to change. To be convinced that this type of person to look upon things from a different perspective, that would allow him to understand more about the reality of change mechanisms. If people feel that those who propose change are closer to their emotions and feelings, they will begin to cooperate and thus will be less resistant to change and thus creates the conditions triggering the change.

b. Communication is another way that can overcome resistance to change, because when people resist change are uncertain. In the absence of adequate communication, there are all sorts of rumors does nothing more than to increase distrust of the consequences of change. However we will avoid the communication and thus reduce the consequences of mistrust in change.

c. participation and direct involvement of members of the organization not only at the implementation level, but also change the design, aims to substantially reduce their resistance to change. Determination of staff to have confidence in her, in its capacity to generate "new" is one of the basic arguments in reducing resistance to change.

3. Creating a vision

Vision describes the future state towards which wants to go change, and contribute to staff in the firm belief that change is based on some acceptable reasons, to be made, that change is necessary and worth the effort that the organization understands him do. When vision emphasizes that changes can not be implemented within the organization, it can lead to lower morale of organization members.

Specialists believe that a step change in any process of change management is to create a vision, encouraging managers to develop its employees' participation, that obviously will lead to support for change, creating a favorable mood. This process involves creating a description of desired future vision and to strengthen the belief and confidence to go in that direction.

Desired future description may include the following elements that can be given to members of the organization, partially or totally:

a. mission, which can be defined before describing the desired state that tends to express the rationale of the organization, including remarks about customers, technologies, markets, etc..

b. the expected results, performance description is that the organization wants to achieve on change, on product innovation, efficient manufacturing processes, increasing staff satisfaction, job security, etc..

c. Expected features are features that ensure the desired results and help define the desired condition for that organization.

Activation of the obligation to help change the description of the desired future state, and among employees is to create an emotional motivation for change. It is sometimes necessary to create different slogans that represent the essence of organizational change and engage staff in implementing a change as it was designed.

4. Finding a supportive policy

Organizations subject to change, it is generally characterized by a diversity of preferences and interests of individuals and / or groups that compose them. If workers follow good condition and very good work, be well paid, employers pursue diversification of the activities and efficient use of resources available to the organization at a time. Marketing department is interested in designing and developing new products while departments are interested in making effective production of the same products.

Under these conditions, both individuals and groups are concerned about the extent to which power is affected, the projected change in the sense that some people will decrease while others will gain strength. Those who gain power will be drivers of change while others will want the status quo. In this case we deal with a state of conflict of interest, which should be solved by those who lead change in the organization, by adopting a policy of supporting the change process.

Establishing a supportive policy is based on the following activities:

a. assessment of promoter strength change, which may be a manager in the organization or a specialist in change management. This assessment allows the promoter to change and set policy on the use of own power to influence others in the process. They are specialists (Greiner and Schein) indicating three sources of power of staff within the organization: knowledge, personality and support of others.

Level and quality of knowledge include specialty training and experience that a person has in that area. Personality as a power source comes from individual charisma, reputation and credibility. A

charismatic leader can inspire confidence and enthusiasm of subordinates. Support others who contribute to increase strength, promote change, facilitating access to certain information, using their relationship in favor of change.

b. identify individuals and groups with an interest in supporting change, such as trade unions, managers at different levels. Simply answer the question: "Who stands to gain and / or lost after the implementation of change?".

c. influence of interest groups, through which the proper motivation of a community as large as possible to achieve change. This can be used ways of influencing another, capitalizing on the benefits, using the system of relationships and overcome barriers to formal organizational system. Recovery of benefits that brings change is based on identifying specific needs of interest groups and informing them on their possibilities of meeting the change. Interest groups may be influenced by identifying and alliances, the Coalition and its use to impose change. Another method that can be used to influence interest groups to be positive change, is to overcome the barriers imposed by a formal organization, specify organization where it wants to implement change.

5. Change Management

Implementing change involves switching from an existing state organization to a desired future state. The transition is not instantaneous, but requires a certain state of transition in which the organization notifies the necessary conditions to reach the desired state. An extension of the transition will inevitably lead to a failure

The leadership change as a state of transition

5. Sustaining change

This stage refers to the situation after the implementation of change, when people still tend to return to its original state at this moment should be to focus on supporting change. This is done through the following activities:

a. provide the resources necessary for change, which are both financial and human, and have an extra character and are only necessary change process. Additional resources are incidental to the conduct of

training activities, consulting, data collection and for various meetings imposed by the change.

b. support the creation of a change, which is very necessary because it can happen that at some point to specific tensions experienced in the process of change primarily those involved in change. The creation of this support comes to help those who would be prevented to carry out the planning tasks to change. This support of change consists of a network of relationships between change agents and people involved and affected by the change.

c. Development of new skills that are required to change and is just knowledge, skills and behaviors of organization members. In many cases the change can not be achieved if such skills are cultivated among the members of the organization. Decisive role in developing these competencies are those which lead him to change and in many cases it takes very much time and resources on their part.

d. strengthen new behaviors by linking rewards to those behaviors that promote change.

Kurt Levin designed the leadership change in stages following:

- opening is to reduce the forces that try to maintain the current organizational behavior. This can be solved through dissemination of information on the difference between actual state and desired state. A propaganda in favor of the desired situation could increase the chances of success of change. change is the shift from an organization or department to another behavior, specific changes introduced into the organization.

- new balance involves the closure of the organization. Maintaining balance is resorting to new means and mechanisms to strengthen the new situation, such as organizational culture, norms, policies and organizational structure.

The Implications of the Migration Phenomenon in Romania

Cristian Elena Raluca

Romanian American University, Bucharest

cristianraluca@yahoo.com

Pădurețu Elena

Academy of Economic Studies, Bucharest

elenapaduretu@yahoo.com

Abstract

In this paperwork we intend to analyze the connection between the behavior patterns of Romanian immigrants, as well as their impact; at the same time, we will try to analyze the way that these patterns are connected to the implications of the migrations phenomenon. Yet, the most frequent question is: after all, what makes the Romanians leave their country? And why our fellow citizens are treated rather differently abroad? Could it be the image that Romania created after 1990? Or is it just a xenophobic attack aimed at a small minority in our country, from people ?

Key words: migration model, economic crisis, migration behavior, cross-culture

J.E.L. classification: F22, Z1

1. Introduction

Recent research on migration and especially research focused on the psychology of cross-culture have shown that there are several acculturation strategies: (integration, assimilation, separation, marginalization) that immigrants embrace. At the same time, these strategies are understood differently by the host country [1].

2. The integration models impact on migration

Christelle Maisonneuve's and Benoit Testé's studies (2007) [2] combine the assumptions of the immigrants being affected by the acculturation strategy. These studies were conducted in France, a country that hosts many immigrants and that adopted an

assimilation policy; thus, the scientists will assess the adopted strategies.

For France, a very nationalistic country, the way that the immigrants are seen is very important: in some cases, even the host population characterizes them using a series of "warm" features, such as tolerant, sincere, competent, intelligent or trustworthy. Another group, the "rich" people group, characterizes them strictly from the professional point of view.

In France, the way the immigrants are seen or portrayed in the local media depends on their nationality or on the ethnicity they belong to, in the end, the whole perception being an entirely subjective one. This separates immigrants into two groups: Asians, European, Indians – characterized only from a professional point of view, and South Americans, Mexicans, Africans, Irish, characterized based on the warm dimension

The research shows that the arrival of the Italians, Spanish, Portuguese and Polish in France in the 19th century did leave a mark, even then; through time, the French population generated a series of social problems. Today, the former immigrants are completely integrated, being a part of the local population; though the previous problems are still brought up, the racism is no longer an issue today.

Cristina Sâmboan [3] analyzed two immigrant integration models, for France and The Netherlands. The author of the study "The Democratic deficit of the European Union from an identity point of view" says: "the immigrant integration policies adopted by the European states have shown, in time, two alternative approaches: an assimilation approach (that doesn't take into consideration the cultural diversity) and a multicultural approach (that encourages the display of

ethnic features), essential to the integration process”

In the same study, Cristina Sâmboan analyzes the European identity, based on two models that she herself calls the French model and the Dutch model (a failed pragmatism).

The first step that France has to take, is the acknowledgment of its multiracial complexity, perfectly dissimulated by the current political class, hiding behind “republican equality”.

The Netherlands is the complete opposite of France, and together with Sweden are probably the best examples for a multicultural model. The Dutch proved to be very open minded towards many problems of the minorities, being considered pragmatic by several countries. The Dutch approach developed in time, starting in the great colonies, and crossing the ocean in the 19th century; the Netherlands, due to historic circumstances, assimilated ethnic, cultural and religious (Christians, reformed, Catholics, liberals) communities, developing its own values.

Despite all these pragmatic policies of the social and cultural indicators, in the 21st century and mostly because of the economic, political, social and racial changes, the immigrant integration process in the Dutch society proved a big failure.

3.“The Romanian migration behavior”

What makes the Romanians choose such countries? Why France, Italy, Spain? The triggers of internal and external migration include a series of interdependent economic, social and ecologic elements, at micro and macro level.

Other factors that influence the migration behavior are: the cultural model (both family and community), education: foreign languages the immigrant knows, the profession the immigrant trained for in the home country, abilities acquired throughout the life, social and especially financial status, the way that population of various countries understand poverty (in our case, the Romanians), the economic crisis or even the “poor man status” – which for many gives an exclusion feeling, at least in our country in the last 20 years after the communism.

The migration is a well known phenomenon for many countries in Europe and even Africa, Asia and South and Central America, even from the Antiquity and The Middle Ages.

Motivation is the only thing that differentiates the countries: for instance, it is a known fact that the Polish were more motivated to migrate than Romanians, for a long time; as for the Irish, migration has become an aspiration, an almost unreal process, as a consequence of the tensed relations with the British in the latest years [4].

Other studies show that age and gender are also important motivational factors: statistics from the latest years proved that the migrating population is forms mainly of young people and men. The exception: the women from the Eastern Europe migrating to the Western countries (Italy, Spain, France, Germany).

According to Daniela Dănăcică: “another explanation for determining the migration behavior is that, in the New World Order, the societies belong to one of the following two categories: meritocracy and oligarchy. Meritocracy attracts the elites, and oligarchy generates the human capital flow for the meritocratic societies. In a meritocratic society, for a person to belong to the elite, he/she has to meet its requirements. This person must be highly intelligent, educated, with imagination, highly adaptive to the new technologies and developments. The oligarchic societies are always generators of human capital flow for the meritocratic societies” [5].

Thousands of Romanian immigrants, arriving in the Western Europe after 1989 created a series of problems for the local citizens who sometimes wrongfully accused them of violence, drug dealing, prostitution. If we analyze our country, we may say that the image that our fellow citizens have created abroad is not necessarily a “very clean” one, being seen by the locals as “public enemies”, as the main responsible with all the wrong things that happen in those places. The EU countries with the largest Romanian immigrant communities are Italy 29,51%, Spain 22,4%, Germany 13,57%, Hungary 5,80%, France 5,53%, Great Britain 4,61%, Austria 4,48%, Portugal 1,98%, Ireland 1,32% [6].

Many Romanian immigrants working illegally were present in countries like Italy and Spain before Romania's accession in 2007.

The intention of migrating or of staying home is influenced by a series of factors like language, cultural barriers, individual personal opinions (of the possible immigrant) on changing the location, leaving the family and friends, changing the country.

Studies and surveys show that Romanians prefer Italy and Spain, whereas UK, Germany and Austria are the least preferred countries. Sociologic studies on immigrant groups prove that there is a migration culture, in which the communication between the undecided, the ones remaining at home, and the immigrant group is very important. The undecided becoming more and more determined to emigrate proves that the existing contact between the immigrant and the one remaining at home is vital for making certain decisions [7].

It is imperative to define the Romanian emigrant profile, from the perspective of the migration phenomenon seen as an important social phenomenon with a significant impact on our country.

Following the studies on migration theories, the focus was set on the role of ethnic, religious networks, thus defining specific immigrant models or patterns, depending on the host country such as: the German model, the French model, the Italian model [8]. The German model emphasizes the role of the invitations from the Germans originating from Romania, for "installing in mobility" of tens of thousands of persons having no other possibility to travel in Schengen area. The French model is specific to a certain type of immigrant, whose social integration takes place "on the street" and it is based on various methods of income. The only way to survive for certain Romanian immigrants belonging to the roma ethnicity is selling old clothes, thrown away home appliances, begging, reselling subway tickets, washing car windows, singing on the subway or on the main streets of Paris.

The Italian model refers to the current Romanian strategy to go to Italy and find a job without complying to all the legal requirements. Within the Italian model, that group of clandestine immigrants looking for a job and wanting to become legal (they

share the same job throughout the year). In the Italian model, the women represent approx 50% of the total Romanian workers in Italy, the main reason being the unification of the family but also the large number of household jobs available. There are many theories for why Romanians choose Italy or Spain. One of the simplest explanations is the language spoken in these countries, Italian and Spanish being easy to understand, both being Latin languages, same as the Romanian; the Latin temper (very warm) is another reason supporting the choice.

The Romanian emigrant, more than any other, once arrived on the Promised Land changes his biography, is ashamed of his origin, of his homeland, his fellow citizens, his beliefs, and hides in the unknown [9]. This country identity loss makes many Romanian immigrants, even religious ones, become prostitutes, thieves, beggars, criminals, involved in human traffic activities. But the most profound effects, with deep implications are the cultural and social ones. Many of the Romanians going abroad to work and bring along their children, relatives, friends, form colonies, leading to real civilization clashes. After 1989, after communism, migration became a concerning phenomenon for state authorities. The Eurostat statistics showed that approx 96.929 persons left the country after the revolution; after Romania's EU accession, 1.700.000 persons emigrated.

Recent studies in Romania show that migration took various forms: it started as a way to reunite the family, then it was ethnic migration (roma requesting asylum in various countries in Europe) or the Hungarian people in Transylvania migrating to Hungary, or business migration (small border traffic), developed through the increase of student international mobility and accentuating after 2005 through the brain-drain (from various domains: medicine, IT, education, engineering) and ending with labor migration, especially the not skilled one: agriculture, construction, household jobs [10].

4. Scenarios for Romanian migration abroad

Migration became an extremely concerning phenomenon, with deep social, economic, psychological and demographic implications, especially after the massive Romanian departing mainly to the EU countries.

This happens especially with illegal migration (without valid papers), much too discussed prostitution cases (Romanian women forced to become prostitutes in Italy, UK, Spain, Germany, France), but also with the traffic of children, old persons with a visible handicap, deceived into begging by a series of networks, also present in Romania.

Anca Balcanu (2008) analyzed the Romanian immigrants in two of their favorite countries (Italy and Spain). The author used as bibliographic source several articles printed in newspapers in Italy, Spain, but also in Romania, and also relying on her own experience of being an immigrant in Italy, for a couple of years [11]. Since 2005 the Romanian community in Italy is a large and even important one, but the question is: "Why do Romanians choose Italy or Spain".

Since 2004 until 2007, the network migration was defining for Italy or Spain, meaning that, some of our fellow citizens, once arrived in the destination country, were looking for a job, without being concerned with legal issues. After the Romanian immigrant had found a job, then he would become interested in settling the legal aspects.

There are certain arguments for continuing the process of decreasing the definitive migration, in the future, slowing down the rate of temporary work migration and for the return home of some part of the Romanians working abroad. One of the domains that proved to be most attractive for the Romanians working abroad was the construction sector, an area severely affected by the decrease of economic activity, with negative consequences on the job market.

Most of the Romanians left the country to substantially improve the financial situation of the ones left at home and, at the same time, to live a decent life. With the economic crisis, here comes the big question: should the Romanians come back or stay in their

destination countries, severely affected by crisis?

The choice between remaining in the western countries and returning home and becoming unemployed is a true dilemma for the now hopeless Romanian immigrant [12].

Under these circumstances, the Romanian immigrants who chose to remain in the destination country focused on other domains: forestry, sheep raising, or other services (in barbershops, restaurants, hotels, tourism).

The impact of migration on the economic growth also has a series of positive consequences for the origin country (Romania), the ones returning home having, in the end, leadership experience and other skills acquired through the various professions or jobs they had [13].

The economic crisis grew deeper in Spain in constructions, the sector that for a long time was considered to be "the engine of the Spanish economy", the decline of the sector generating the crash of the real estate system, many people losing their jobs, among them, our fellow citizens [14].

This adds to the French campaign against Romanian Roma immigrants, but also to the recent events in Italy against Romanian immigrants, especially the killing of a Romanian woman by a young xenophobic Italian, at the end of 2010, in a subway station in Rome.

Another argument is the labor force deficit in our country, caused, partly, by massive emigration of skilled people in various fields: construction, healthcare, education, textile, shoes, commerce.

Recent Eurostat studies, quoted by the National Statistics Institute show that migration phenomenon will still go on for approx. 10 years; until then, our country is facing low birth rate, high death rate and high aging process, an Europe-wide trend.

For the next years, specialists estimate that the main target countries for Romanians will be the countries in the western and southern part of EU, and studies show that, in the next five years, the migration to Italy and Spain will slow down, and our fellow citizens will focus on Germany, Ireland, Belgium, Sweden even France. The money the emigrants sent in the country after 2002 contributed rather insignificantly to the economic growth.

As an answer to the media debate about Romanian emigrants Silași and Simina (2008) consider that the fear towards the immigrants from Romania, after 2007 is not justified, and maybe too exaggerated by foreign press [15].

While the European media (mainly the British, French, Italian and Spanish) complain of the threat of Romanian and Bulgarian emigrants, scientific reports say that the countries of origin of the immigrants receive an important economic support from the EU countries. At the same time, Romanian media and entrepreneurs talk about the Chinese invasion and the lack of labor force in constructions, industry and agriculture.

Labor market in Romania, between 2007 and 2009 was a destination attractive enough for much poorer non EU countries. If we were to create a scenario, did not take into consideration the economic crisis and introduced a variable: economic growth in Romania based on increased investments and new jobs, and if the ones gone abroad didn't return, Romania would become an immigrant country.

5. Conclusions

From a country – source of immigrants, Romania will become a destination for citizens in the eastern countries – including central Asia, the Asians looking for better wages and working conditions than in their country, but also for benefits coming from working in an EU member state.

The latest statistics on the Romanian employers show that in our country the companies will have several other options: either to employ skilled Romanian workers or to employ foreign workers at much lower wages.

Europe faced in the last years major challenges: accession of 12 new states, the ratification of the European Constitution, the common budget for 2007-2013, several social movements with ethnic motivations, a new agenda for security, justice or labor force mobility for the new member states. Among the most debated topics were the liberalization of the labor force market for the new EU citizens and the accession of new member states to Schengen area.

Divergent Economic Growth and Employment Conditions within the Euro Area

Cristian Ovidiu Ștefan
„Babes-Bolyai” University of Cluj-Napoca
ovidiu.cristian@econ.ubbcluj.ro

Abstract

We present evidence that the process of euro adoption and the creation of the Economic and Monetary Union has enhanced the economic growth of the Euro zone and has determined better conditions on the labour markets.

Still, these developments are not homogenous across countries. There are important differences in the rate of GDP growth, the increase in labour productivity or employment conditions. Moreover these conditions tend to be persistent across time, weakening the belief that once the euro is adopted, countries tend to converge economically.

Key words: UEM, divergent, growth, productivity, employment

J.E.L. classification: E23, E24

1. Introduction

Twelve years after the start of the third stage of EMU, on 2nd of May 1998, and the introduction of the common currency on 1st of January 1999, the euro has become one of the most recognized symbols of Europe. It is associated by the majority of European citizens with the remarkable results that took place in this short period of time, being identified as the main reason for the ensuing economic stability, trade increase and accelerated financial integration that happened within the borders of the Euro area. From the eleven states that initially adopted the single currency, the number increased at seventeen currently, and the final goal is that in the future all the countries that belong in the European Union to participate also in the Economic and Monetary Union. The European Union, through its 27 members, represents the most powerful economic entity

in the world [1], surpassing the United States of America in the share of total world GDP.

At the moment of euro adoption, the desire was to achieve two main goals [2]: first, it was hoped that a more stable macroeconomic environment will develop, through the elimination of the inherent exchange rate risks and the increase of political credibility; second, it was expected that the economic efficiency will increase, through the elimination of the costs associated with currency transactions, the positive effects of price transparency on competition and through the acceleration of economic and financial integration.

After more than a decade, reaching a high level of macroeconomic stability is probably the most important result of the single currency introduction. The coherent monetary policy conducted by the European Central Bank, policy that was specifically targeted at inflation containment, achieved the consolidation of future inflation expectations, with remarkable effects. The average annual inflation in the euro area during the first ten years of euro existence was around the desired target of 2%, compared with 3.3% during the '90, or 9.3% and 7.5% during the '70 and respectively '80 [3]. Unfortunately, during the last years, inflationary pressures have emerged in the Euro area, mostly because of the negative effects induced by the international price increases of food and energy. It is hoped that the European Central Bank will contain these pressures, with minimum spill over effects in the real economy.

If the goal of high level of stability was met, unfortunately the optimism concerning the economic growth fuelled by euro introduction was not founded. In the first ten years, the annual average GDP growth was around 2%, at the same level with the average growth recorded in the previous decade. Moreover, the average GDP per

capita growth remained at the same level recorded in the United States of America [4], thus maintaining the economic disparities between the two economic powers.

The process of financial markets integration was accelerated after the introduction of the single currency. The monetary markets were fully integrated, while the cross-country financial transactions increased after 1999. On the other hand, even if the state bond yields converged a lot after the euro introduction [5], currently, in the midst of the economic crisis, the differences are yet again increasing, reflecting the elevated perceived risks that some countries possess. Reducing the economic disparities between countries was another aspect that was facilitated by joining EMU. The macroeconomic stability, the low interest rates, the implementation of cohesion policies or the possibility of accessing structural funds, all created the perfect conditions for accelerating this convergence process. Thus, it is no surprise that the majority of European countries are striving to meet the objectives needed in order to adopt the euro currency also. In this process, euro became in a short period of time the second most important international currency. Euro represented 25.9% of the total international currency reserves in the first quarter of 2009, compared with only 18.3% in the last quarter of 2000 [6]. This increase hurt mostly the American dollar, which diminished its quota from 71% to 64.9%, during the same period.

2. Divergent economic and productivity growth in the Euro area

The euro introduction spurred many positive effects, which in the end increased the economic development of the euro area. These effects were most visible in the area of GDP growth, which was mostly determined by the increased competition and the economies of scale. Nevertheless, the difference of about 30% between the American living standard and the European one persisted. This fact can be explained by the different growth rates experienced between the big and small economies of the Euro area. If the annual growth rates from the small European countries surpassed most of the time the average annual growth rate recorded in the United States of 3%, the big

European countries – especially Germany, Italy and Spain – lagged behind this figure.

If in the decade preceding the euro introduction the annual GDP growth rate in Germany was around 2.5-3%, after the single currency adoption, that rate decreased to 1.5%, while in the case of Italy, the annual GDP growth rate stood at 1.5% before and after the euro adoption [7]. In the case of Germany, this was determined by the incomplete process of East Germany integration, which in turn determined the existence of a weak internal demand and increased wage pressures coming from the eastern workers. On the other hand, Italy was disadvantaged by the existence of an industrial base that entered frequently in competition with the existing base from other emerging countries. As a result, Italy lost in the last years important market share, with immediate effect on its economic performance.

The case of Spain, the fourth biggest economy of the Euro zone, is a special one. Here, the economic growth was determined mainly by a boom in the construction sector, a phenomenon facilitated by the reduction of the interest rates and the increase in immigration. Because it was not based on trade, this specific sectorial growth determined a worsening of the current account, and this situation started to stabilize only in the last period, when Spain's economy started to cool down. Still, the negative effects are still present, the official unemployment rate in Spain currently exceeding 20%, with advanced talks of external financial assistance taking place.

Regarding the small countries, Greece and Finland had an accelerated growth after the euro adoption, while the economy of Ireland grew at a fast pace before and after the introduction of the single currency [8]. Until 2008, the year when the global crisis had a tight grip on the world economies, the growth rates from these three countries were superior to the ones from the United States of America or Great Britain. It must be noted that other countries did not fare so well, and it is worth remembering Portugal, which after the euro adoption, registered a weaker economic performance. In this case the economic unbalances that accumulated in the decade before it entered the EMU – increased current account deficits, high individual debt

and increased fiscal deficits – played an important role.

As a comparison, the growth of GDP from the central and Eastern Europe was even higher than the average recorded in the EMU [9], in the first years of euro introduction. Moreover, the GDP fluctuations from Poland, Slovenia and especially Hungary is more correlated with the GDP fluctuations from the Euro zone as a whole, than the GDP fluctuations of Greece and Portugal. This is a highly positive fact for the countries desiring to switch (or have already switched) to euro currency in the near term, because in their case the stabilisation costs associated with the adoption process are thus smaller.

If the economic development of the Euro zone, analysed through the GDP growth, was a satisfactory one, the increase in labour productivity was far from optimal. In the period 1989-1998, the average yearly increase of labour productivity was 1.5% and during the period 1999-2008, this decreased at 0.75% - compared with the United States of America, where the average yearly increase of productivity stood in both periods at 1.75% [7]. The countries that determined this situation were Italy, which after 1999 did not increase its labour productivity, and Spain, which after 1999 experienced even a decrease in its labour productivity, even if in the '70 and '80 this country was engaged in an accelerated process of catching up with the other big European economies. The situation in Spain is just a stark reminder that even in the case in which the real convergence takes the form of a gradual process, the dynamic response of the macroeconomic variables can be disruptive to the economy [10]. Moreover, the unrealistic expectations of the economic participants regarding the future increase of productivity solely as a result of the euro adoption can generate major crisis situations, as it was seen.

The sub optimal results registered in the field of labour productivity, when compared with the United States, were determined by the differences existing in just a few economic sectors, mainly the information technology and communications (IT&C), real estate and financial services [11]. In the case of IT&C sector, this benefits from the bigger size of the companies existing in the US, which thus can afford bigger investments in

R&D; for the real estate and financial services, deregulation played an important role in their faster development when compared with Europe. Nevertheless, the risks associated with these deregulations were much higher, and the consequences can be clearly seen today.

The notable exceptions from this trend were the Nordic Countries belonging to the European Union. Denmark, and especially Sweden and Finland registered high labour productivity rates, superior to those from the first four economies of EMU – Germany, France, Italy and Spain – and equal to those registered in the USA. If in the case of Sweden and Finland the growth of the productivity rate was based on the production part of IT&C, as well as the services that use IT&C, in Denmark the high rate of productivity growth was based just on the services that used IT&C. Regarding the production sector of IT&C, Denmark was behind Germany and France. The IT&C sector is characterized by a very fast technological progress, increased competition, frequent downward price movements and a high increase of productivity rate [12], and not many countries can excel in this particular economic sector. The increased competition from the financial and product markets, high investments in research and development, a highly skilled workforce and the availability of venture capital were all prerequisite conditions for the success that these countries experienced.

At the firm level, it was discovered that the main contributors to the increase in productivity rates were the large (250-999 employees) and very large (more than 1000 employees) firms, especially in the periods with high productivity growth [13]. Also, in the old firms, with a lifespan of more than 20 years, the productivity levels tend to increase faster. Regarding the technological level, firms that activate in sectors less technologically intensive have a smaller contribution to the increase in productivity, a fact that can explain the widening gaps between the industrialised countries and the countries that have not still succeeded to introduce the advanced technologies on a wider scale.

3. Divergent employment conditions in the Euro area

After the euro adoption the European labour markets were also – at least theoretically – opened. Still, at over a decade away from this event, the labour mobility on this market can be considered at best moderate. There are a lot of factors [14] that can account for this fact, among which it is worth mentioning:

- Legal and administrative barriers;
- Cultural and linguistic differences;
- The costs associated with moving in another country;
- Problems from the real estate markets, especially high prices and high rents;
- Limited possibilities to transfer pension benefits from another country;
- Lack of clarity regarding the international recognition of professional qualifications;
- Lack of transparency regarding the vacant positions.

The evolution of the European labour market can be characterized as a positive one, especially after the euro introduction. During the period 1996-2007, the increase in the number of employed persons accelerated, over 21 million new jobs being created [15]. This fact contributed to a 3.9% reduction in the unemployment rate, so in the spring of 2007 the unemployment rate stood at 7.5%. Also, there was an increased participation on the labour market of certain working categories during this period: women, with an increase of 9%; migrant workers from the new EU states, or states situated at the periphery of EU, with an increase of 7.4%; and old age workers, with an increase of 10.5% [15]. The yearly rate of new job creation after the common currency adoption was impressive, from an estimated 0.5% yearly before the euro, to 1.25% after this event. This increase took place in all countries, the only notable exception being the Netherlands, which saw its rate of new job creation reduced in half after entering UEM. On the other side the speed of job creation in Spain was impressive, from a 1.5% annual average before euro to over 4% annual average in the first ten years after the adoption. Still, after the emergence of the global crisis, this explosive development

transformed itself into a vulnerability, at present, as already mentioned, the unemployment rate in Spain exceeding 20%, with all the negative consequences that it involves.

Another perceivable event that happened in the Euro zone was the increase in labour quality, determined by the increase in the participation of workers with tertiary education. Even if this increase was higher in the '90 compared with the '80, still, after the euro introduction, the speed of labour quality increase slowed, probably reflecting the impact of an increase in job creation, which attracted on the job market workers less qualified [16]. This increase in labour quality accounted for 30% in the rate of labour productivity growth in the euro area.

However there are some negative aspects regarding the process of labour market integration, and probably the most important is the increased income inequality. The economic integration determines this increase in inequality, because workers are subject to international competition, and the unions that activate at the national level are weakened. Moreover, there is a tendency for reducing social assistance, because the supranational mechanisms impose on the member states austerity measures needed to reach fiscal stability [17]. Again, the most affected by these measures are the less developed states, with a poor population that is dependent on this social help. The economic crisis demonstrated that in these states the measures implemented in order to reduce the fiscal imbalances - salaries and pensions reductions, increased taxation - had a direct impact on the less wealthy categories of population.

At the state level, these differences between wages persisted over long periods of time, weakening thus the belief that entering the Euro zone will automatically lead in time to wage convergence. Moreover, when analysed even on sectors of economic activity – agriculture, industry, trade, transportation, financial services – the differences from country to country remain [18], even if in the same country the sectorial wage increases experienced different speeds during the period 1993-2006.

At the Euro zone level, the theory which states that wage levels tend to be the same for workers with equivalent qualifications and working in the same industry is not valid. In this case the connection between wage and productivity is not so tight, being influenced by specific factors as the unions` bargaining power or the market share of the employing firm [19]. If this market share is consistent and the firm has a dominant position, it also has a higher incentive of giving higher bonuses to its employees. Thus, in this way the employees belonging to companies which operate in big, mature economies have an advantage, because in these countries exist the big majority of companies that dominate the European marketplace. At a sectorial level, it was determined [20] that the highest wages belong to the extractive industry, the oil industry, nuclear and chemical, public utilities and insurance and financial industry. The lowest wages are in the textile, leather and footwear industries.

The reforms from the Euro zone labour markets were extensive, especially in the period before the introduction of the single

currency, and resulted in the creation of additional jobs. Unfortunately, after the euro adoption, the initiatives were directed just at certain economic sectors or at small groups of participants. Moreover, it cannot be affirmed with certainty that the budgetary costs of these measures justified the benefits. The most important initiatives [7] were in the field of taxation, unemployment benefits, reforming the national labour institutions and trying to increase the mobility and flexibility of the labour market.

- Wage related taxes decreased in the majority of European countries. Tax reductions were aimed at individuals with low incomes, long term unemployed, young and old workers;
- Almost all countries adopted measures targeting the unemployment. These included stricter rules for reporting vacant jobs, sanctions for non-complying with these rules, and more efficient control mechanisms;
- The legislation concerning part-time and flexible time employment was upgraded. Temporary working contracts were also better regulated and the process of converting temporary contracts into permanent ones became easier.

The increase in employment in the Euro zone was impressive, suggesting the fact that the reforms from the labour market were well implemented. The number of the employed persons grew on average with 1% annually in the period 1998-2008, the average employment rate growing in this period from 62% to 68%. All the Euro zone countries experienced a growth of the employment rate in the period 1998-2008. In the same period the US economy experienced a small decline in the employment rate. It is worth mentioning that there still are major differences between countries – if in Greece the employment rate in 2008 was 57%, in countries like the Netherlands or Denmark this figure was close to 80%.

Conflicts of Interests between Actors Involved in the Corporate Restructuring

Croitoru Daniela

„Alexandru Ioan Cuza” University of Iasi

daniela.croitoru@gmail.com

Abstract

The article aims to highlight conflicts of interest that can occur between different actors that are involved in operations of corporate restructuring. They highlighted two main theories explaining the relationship between shareholders and managers, namely the mandate theory and agent theory. To resolve conflicts that may occur between participants in the mergers and acquisitions have developed codes of corporate governance to harmonize the interests of those participants. The paper stresses the impact of restructuring operations both financially and socially from the opportunity to keep the place held company that was acquired. Experience of various corporations require greater caution in starting operations said that in view of the results that will be achieved on medium and long term.

Key words: M&A, mandate theory, free rider, defensive strategy.

J.E.L. classification: D92, F23, G34, O16

1. Introduction

It is considered that the force that gives impetus to economic processes in line with the trend of globalization is the multinational corporations. Modern Corporation is no longer in the foreground to achieve a certain level of profit but also increase its accountability to managers, shareholders, directors, employees and even managers. How the corporation relating to these categories of actors can have a major impact on performance and organizational culture of that corporation.

Classification of mergers and acquisitions is covered in the literature in a complex differ significantly from one author to another. In addition, classification of mergers and

acquisitions in the shape of fusion or absorption, in legally term, there other grouping, in terms of: participating companies, attitude of management team towards restructuring, activity, motivations that justify this operations, etc.

In general for studies on mergers and acquisitions (M & A), analysts exclude transactions where the state is participating in these operations are considered "privatization." This approach is sometimes challenged because privatization transaction always involves the participation of a private entrepreneur, who actually made the purchase. It is recalled that the first approach eliminated from analysis greenfield investments, focusing on existing businesses.

Among the main reasons that were based on mergers and acquisitions of the 1990s, we can mention a few: debt financing, "one-stop shopping" financial engineering, distribution, diversification and economies of scale.

One-stop shopping "is an incentive to restructure operations in the idea to build a supermarket of financial services to customers. Directors of the merging companies have regard primarily economic issues other transaction, paying attention to possible synergistic effects. Although many such effects are not expected to materialize for gaining in all the companies, participants in such transactions do not leave discouraged.

Another justification given is that with the acquisition of other companies, products outlets can be extended so that a part of a company's suppliers and customers become customers or suppliers and other company.

The majority of companies who participated in the restructuring operations in the '90s were warranted by the emergence of economies of scale, data in most of the reduction in the number of employees with the formation of a new corporation. Many companies participating in the reorganization

transaction as "white knights" have regard to a financial incentive, namely the tax benefits they may bring further large gains.

2. Mandate theory

Mandate theory explains the relationship between owners and managers, stressing the need for separation power of initiation and implementation of decisions made on the degree of control of decision making. The relationship between shareholders and managers is defined as a contract whereby the principal employ a person, named agent to perform certain tasks, leaving the right to take decisions. It is possible that the agent does not fully comply with established rules and therefore need a check made by the principal.

The principal will always follow specific clauses in the contract to consider pay agent so as to be boosted to effectively coordinate and on the other hand clearly establishes control procedures on the latter. In the case of the agent, it is concerned to take those decisions to settle the principal and which is in line with expectations.

A first method of showing the relationship between principal and agent is dominated leadership in the planning, the overall activity of the corporate vision is influenced by shareholders, knowing her best work, even if based agents and plans developed.

An effective relationship between the two parties in the planning is dominated by organizational culture in which all members of all operational units communicate and are dominated by the same principles of organization and management and working to benefit the corporation as a whole.

Predominantly operational planning states that the main role is for agents who needs to know very well the entity where they operates so that decision take by them bring positive results to the corporation. They must be informed of every detail of the corporation and be able to clarify any aspect of the decisions taken to help shareholders understand that they have been taken in the interest of the latter.

Practice generated new mechanisms that compel managers to act in the interest of shareholders.

A first way to resolve the conflict between shareholders and managers is the managers

incentives based on performances, which motivates them to act so as to maximize the company's share price on the market. Incentive schemes for managers take the following forms:

- Management Incentive Plan as "performance shares," consists in offering shares to managers based on performance evaluation obtained by the company: earnings per share, the rate of return on assets, rate of return on equity;
- Options for managers to acquire shares of the company in a future time, but at a price fixed today. This incentive management was practiced in the years 1950-1960 but fell into disgrace in 1970 after options proved to be unprofitable;
- Provide bonuses to managers base on profit made by the company.

Another way to resolve the conflict between managers and shareholders is the power of the Board decision that has important powers in the control of managers. In some countries, the Board has veto power and retain power to revoke its chairman.

Another way of solving disagreements shareholders-managers is to vote by proxy. In practice this operation is difficult because one shareholder fails to gather sufficient votes from other shareholders to change management team. Usually found in the transaction involved a shareholder who owns a small percentage of the capital.

The presence of the reference shareholders is a more effective control of managers. They are fully motivated as the company invested significant amounts to be profitable and therefore putting pressure on managers materialized in important decisions and effect.

Takeovers of companies by buying shares - another way of solving conflict - especially when held capital of the company is undervalued due to a succession of wrong decisions of the management team. Usually, following the acquisitions, some managers are fired and those who remains, lose their independence that they had in corporations before the takeover.

On the operations of state enterprises privatization, they have emerged as a response to the need for change within the system, aiming to find owners animated by the desire to ensure a rational use of

resources and improve the profitability of their businesses. Change of the ownership schedule will not modify the attitude of managers if the new owners will not have power, motivations and resources to control their activity and to supervise them to act in the interest of corporation.

Therefore, subject to privatization it is not only legal transfer of ownership of business assets but also a transfer of decision power, control and sanction for new owners, and creating an institutional infrastructure and appropriate mechanisms capable ensure an effective corporate control.

As seen from the experience of countries with developed market economy, development and improvement of corporate governance mechanisms was determined mainly by the difficulties that arise in relations between shareholders and managers due to different interests and objectives pursued by the shells, and different time horizons had to each of the two categories of "actors". Relevant issues, adds that are usually when there are many small shareholders holding equity shares in the company is too expensive for each of them to do the analysis necessary to ensure that managers act in their interest each shareholder prefers to be "free rider" (free rider), or to receive certain benefits without paying.

For Romanian privatized enterprises, the issue of corporation control and of suitable mechanisms for its performance is more important, taking into account: ownership structure and behavior resulting from mass privatization process, lack of adequate mechanisms to protect minority shareholders, maintaining in some of the privatized companies of significant holdings of state, reduced performance of many enterprises, the presence in the Romanian economy has a stock market system and over with an unattractive development, capital market but with the emerging character.

3. Impact of the privatization on power structures within the corporation

Privatization program in most countries in transition aimed at creating a new class of entrepreneurs and thereby ensuring effective control of shareholders on corporate managers resulting from the reorganization.

Managers are those who know best the corporation and they have knowledge and experience, being invested with necessary decision authority. They, usually must be those who supporting change at all levels and must take all necessary measures to support those measures that follow restructuring through privatization.

Many times, managers are opposing to privatization, giving two reasons: ore disagree with the propose of the Government, or they are pursuing own interests and a possible reorganization could affect the position within the organization.

The opposition of managers are based often on the following factors: political, professional incompetence and luck of initiative for some managers.

Political factor. Some managers were satisfied, especially in communist countries with the old regime and they not accept new reforms within corporation owned by state.

In some countries, managers don't have all the information they need to take right decisions asked by an economy being in transition, especially for those countries who faced a centralized economy. Besides, the possibility to lose their jobs at the same time with the privatization, the managers take attitudes to stop all measures that takes into account restructuring of the ownership.

Other reasons that are discussed when talking about privatization is the legislative framework which could provide the conditions necessary for the carrying of changes regarding ownership of the new corporation. Managers that come with this reasoning, actually trying to hide the benefits they have in the state enterprise through control rather low and the legal framework with many flaws and shortcomings.

Regarding the attitudes of employees and unions they usually show passive until the start of operation by public offering. Their greatest fear is of losing jobs and benefits they were inside before the corporate reorganization procedure. Experience from other corporations that have directly led to improved wages and working conditions for them to look with suspicion on the future possibility of obtaining a higher income than that received in the period before privatization.

Risks that might arise from misunderstandings and different goals of stakeholders can be:

- Onset of labor disputes aggressive, often escaped the control of unions;
- The manifestation of aggressive behavior towards privatization originators;
- Creating confusion and uncertainty among employees.

4. Cultural barriers between corporations involved in restructuring operations

In line with much of the recent studies, acquisitions fail due to cultural differences between companies participating in the transaction.

The main motivation for mergers is costs reduction but this is not the main effect of those operations. Restructuring operations can be influenced by cultural types in three ways. (Terrence D., 2000).

First, it's about an effect called "look over your shoulder". Employees will follow every time which will be departments that will disappear after the merger and that will affect their jobs. After the merger is announced, teams of the both companies will start to ask which part of ax will fall first. Look over your shoulder and gossip about who shall leave company and who shall stay, are parts of experiences of such operations.

Secondly, is the effect "winners and defeated". A party participating in the transaction will win while the other, usually the target company almost always lose their jobs in the new company. Winners are those who adapt together. How did it always, take decisions without consulting and impose their own desires. As a result, the losers are withdrawn one by one, using their skills and knowledge elsewhere where their opinion matters to the company.

Thirdly, we are dealing with an effect of cultural isolation that occurs when those who work in the new company realizes that it differs significantly from that for which they previously worked. The cultural differences are more pronounced, with the more difficult for newly established corporation to start up with high expectations. In this case, how management companies involved will know their responsibilities and communicate așeptările will limit the negative effects that

may likes because different perception on the functioning of corporate.

If the executives realize that cultural issues can be an obstacle in obtaining the expected results, they could build a new culture within the new company combining the best features of the merged, creating a stronger company and with remarkable results.

Studies on the success or failure of acquisitions warns that friendly acquisitions are generally more open in terms of successful integration of the two corporations. Managers of participating companies are open to negotiation are more flexible to better effect change and realize mutual understanding and make greater efforts to adapt their goals and visions.

In contrast, hostile mergers provide an overall framework for adaptation unfavorable, given the misunderstanding between the two firms top managers who are dissatisfied with the operation and success will follow their own interests and not those relating to obtaining positive results for corporate. Grievances that may arise as implications and departure of employees base due to clashes between different corporate teams engaged in corporate.

In practice of mergers and acquisitions involving entities from different countries were observed following methods to deal with cultural barriers (F. Trompenaars, 2004), namely: "a dominant strategy (in which the controlling impose its vision), leading to a defensive strategy to resist domination by the other strategy tolerance (both parts interact as true partners) and ignoring the differences between the views of participants.

Dominant strategy, defensive and of removal share an essential feature, representing lack of respect, which may have as result the impossibility of reconciliation between two types of cultures that meet within the new corporation. Dominant strategy can only attract an defensive attitude from those who feel neglected and can lead to failure of the merger or acquisition. Before the synergies effects appear.

Many corporations have adopted early merging activity tolerance approach so that each mode pursue their responsibilities. But this lasts until the enterprise is faced with the need to make strategic decisions that may affect the future of those involved, since the

pronounced differences will occur. Stakeholders should examine their own shortcomings and issues so important that they have other partners that may be used in the corporation to create new value.

5. Conclusions

Should be considered not so much the impact of these operations on the main players involved in their running and their effect on employees, who very often are those that give impetus to corporate activity and will increase its value. Taking into account the overall economic situation, characterized by a crisis of liquidity and investors, the impact of mergers and acquisitions can be a disaster on hundreds or even thousands of employees.

Perhaps too much emphasis on economic and financial implications eliminates a primary objective of these operations, namely that of increasing social welfare and establish favorable working conditions for employees at the lowest hierarchical level.

With the outcome of such strategies should be given special attention and measures are taken to stop them even if these intentions are sometimes justified and substantiated. Imperfections and shortcomings in the law of mergers and acquisitions can provide the favorable application of such measures may lead to job losses of employees with an effective work to reduce the value of the firm, becoming unattractive not only for raider, and for other providers would be desirable to invest in the corporation in question.

Foreign Direct Investments on the Economic Crisis Background

Croitoru Daniela

„Alexandru Ioan Cuza” University of Iasi

daniela.croitoru@gmail.com

Abstract

The article aims to highlight the EU directives issued to protect the interests of different categories of actors that are involved in restructuring operations and the operations against the background of the current economic crisis event. A further issue highlighted in this paper is on the state of mergers and acquisitions in Romania and their medium-term trends. Even if the current economic situation reduced resources for funding, however, many corporations realize that restructuring operations are a method necessary to implement for exiting the crisis. Thus, shareholders prefer to invest alongside other partners to strengthen their financial position in the market where it operates.

Key words: restructuring, FDI, M&A, III Directive, transnational corporations

J.E.L. classification: D92, F23, G34, O16.

1. Introduction

Restructuring operations primarily considering mergers and acquisitions taking place to achieve economies of scale and to save or development of certain businesses. The procedure for such operations is quite complex and must take into account both the financial aspects and those linked to corporate social responsibility towards employees taking part in the restructuring.

Watson Wyatt has implemented a model applicable in carrying out mergers and acquisitions, emphasizing the most important phases of an operation of financial reorganization, emphasizing in each of these, the objectives that represents basic issues that must pursued in each phase.

According to Galpin & Hemdon (2000, p. 8), any merger or acquisition should follow the following process: strategy formulation,

market and location of a target company, the financial aspects of its analysis, negotiation of conditions of corporate reorganization and integration involved in that operation.

2. EU Directives on mergers and acquisitions in order to protect the interests of stakeholders

Under Articles 13 and 14 of the Third Directive, it lists some guidelines concerning the protection of creditors but are made vague. They explain that the laws of the Member States of the European Union must adopt a system of adequate protection for the interests of creditors will participate in merger companies before publishing the conditions necessary to carry out the operation in question.

Regarding the restructuring of these operations recorded in the European Union following table provides a summary of their evolution from 1987 to present.

Table no.1 Cross-border M&A's (valued at over \$ 1 billion, 1987-2009)

Year	Number of deals	%	Value	%
1987	19	1.6	39	40.1
1988	24	1.3	53	38.7
1989	31	1.1	68	40.8
1990	48	1.4	84	41.7
1991	13	0.3	32	27.0
1992	12	0.3	24	21.0
1993	18	0.5	38	30.5
1994	36	0.8	73	42.5
1995	44	0.8	97	41.9
1996	48	0.8	100	37.9
1997	73	1.1	146	39.4
1998	111	1.4	409	59.0
1999	137	1.5	578	64.0
2000	207	2.1	999	74.0
2001	137	1.7	451	61.7
2002	105	1.6	266	55.0
2003	78	1.2	184	44.8

2004	111	1.5	291	51.5
2005	182	2.1	569	61.3
2006	215	2.4	711	63.6
2007	319	3.0	1197	70.4
2008	251	2.6	823	68.3
2009	40	1.2	171	67.2

Source: UNCTAD, cross-border M&A database (www.unctad.org/fdistatistics).

In the series of data presented it appears that the period considered, 2000 has seen a substantial increase in the number of mergers and acquisitions transactions that took place after their declining until 2006. 2009 was marked by an overwhelming change of foreign direct investment due to global financial problems have worsened, the number of transactions reaching the years 1990-1995.

Graphic no. 1 Transnational mergers and acquisitions over 1 billion USD (1987-2009).

Source: www.unctad.org

As observed from the chart, the years 1991-1993 showed a decrease in high value transactions made possible by the collapse of communism, many local companies being privatized in favor of more foreign companies but with a very low cost.

3. Theories on conflict of interest between shareholders and managers

Traditional theories dealing with the issue of relations between managers and shareholders watched first as persons who manage corporation taking into account only their own interests, acting and taking decisions which are detrimental to shareholders and all other categories of corporate stakeholders. Managers were seen as those categories of people which not creates value to the corporation but hinders

the achievement of high performance and creating a positive image corporation.

This vision has not taken into account the beneficial impact it can have on corporate and business managers can create value precisely because of decisions taken by them.

In contrast, modern theories take account managers need freedom of action while reducing the role of authoritarian control mechanisms even though this may come at the expense of shareholders by making decisions on investing to reduce the risk of replacement managers. In light of these theories, managers do not seek protection of their interests but concentrate on achieving high performance at a corporate level to earn a reputation on the job market so that potential employers have a positive image with regard to their powers.

In recent years increased the role of small shareholders, which resulted in changing relations between them and managers, for shareholders. If in the case of corporate restructuring and development, small-shareholders were not opposed but had as one option, the sale of shares today have formed groups to represent them and protect their interests, supported by financial specialists.

At corporate level, an effective governance system must consider each entity involved in the group without diminishing the role of categories of stakeholders and without granting privileges to others.

Approach to relations between actors involved in the specific activities of corporations varies depending on the differential patterns adopted countries or groups of countries. Thus, issues of discipline managers in Europe and Japan implies a pluralistic model in Dan Vasile's conception (2004, p.82) in which the interests of employees play an important role, while for U.S. companies require a one-tier model, the essential link is the ownership.

Also, managers can make decisions to invest depend on which performance information they have, so eventual removal from office to bring major corporate losses, stranded. If shareholders wish to remove the management team they can manipulate the information so that potential competitors do not learn about that job availability.

Often the separation of ownership and control resulting effects are diminished by

the fact that managers often have the actions of their corporations and are interested in obtaining a higher level of profit, so that dividends are an appropriate size. Knowledge of quality relationships between managers and shareholders in the privatized corporations are important, mainly for some aspects, such as providing an overview of how the change of ownership has led to a high degree of incentives of managers and employees about efficiency of the entity in which they work.

Attitude towards shareholders is primarily aimed at managers distrust that they have because managers are often interested to reinvest a portion of profit while shareholders are considering a dividend increase.

4. The level of Foreign Direct Investment

According to estimates, global FDI flows in 2008 declined by 21%, reaching 1.4 trillion USD. This trend is due to start global economic downturn, tightening credit conditions, falling corporate profits and uncertain prospects for global growth in the short term. The effects of global crisis varies between regions and countries, thus printing a different impact on the geography of FDI flows.

Graphic no.2 Evolution of FDI worldwide

Source: Data processing after UNCTAD, WIR 2004-2008;

Preliminary data for 2008 reveals that in many developed countries attracted FDI flow has significantly decreased by 33% compared with 2007, due to deepening problems facing the crisis of financial institutions and money market liquidity. Reduced revenue of transnational corporations from developed

countries and lower bank loans unions have significantly limited investment funding.

In developing countries and those in transition, preliminary data for 2008 indicate a modest increase of 4% of FDI flows from the previous year, compared with 20% growth registered in 2006 compared with 2007. In 2008, Africa attracted FDI flows to exceed 60 billion recording a growth rate of 16.8%, amid slowing economic growth worldwide and the negative impact on the region.

Table no.2 Transnational M&A in Romania (millions of USD)

	Sales		Acquisitions	
	Year	Value	Year	Value
RO	1990-2000	293	1990-2000

	2006	335.738	2006	265.714
	2007	526.486	2007	538.536
	2008	224.575	2008	302.826

Source: UNCTAD, World Investment Report 2009

In 2006-2007, the Romanian economy faces a number of issues arising from the transition process and amplified by: delaying completion of privatization, slow restructuring of economic sectors of activity, a relatively small number of banks, insufficient training of managers, difficulties in functioning in a competitive market.

Other reasons that gave rise to the acceleration of the process of the economy are: the existence of a small number of entrepreneurs to develop well-founded marketing studies to provide reliable information on the current situation and perspective on various internal and external markets, low level of technical situation of R & D units.

5. Prediction about the level of foreign direct investment in the medium term (2010-2012)

In the medium term, there are three scenarios that forecast developments in foreign direct investment in the next 3 years (2010-2012). The level of mergers and acquisitions depends on many factors, such as the global economic downturn, low efficiency of the financial policies of states in recession, in response to the global economic crisis (in particular those initiated to stimulate transnational investment). One of the problems is ambiguous when referring to the level of mergers and acquisitions will increase again, since they are major components of FDI.

Scenarios that show how they will evolve in the next period are: Scenario V (optimistic) scenario U (base) scenario L (pessimistic).

Scenario V optimistic forecast a rapid increase in the level of mergers and acquisitions in the second half of 2009 due to increasing investor confidence through effective government policies, a new wave of industrial restructuring and investment due to the existence of liquidity in some companies or financial institutions. As seen today, this scenario does not reflect reality, considering that both the EU and global level of investment continues to know a prominent decrease.

U scenario requires that the medium term, FDI will increase only in 2011, bringing the motivations: recession will last at least until the first half of 2010, the value of mergers and acquisitions remains limited because of low prices of the shares undervalued.

Scenario L (pessimistic) concludes that the restructuring operations will decline in 2012 because it believes that corporate leadership is skeptical about the effectiveness of investments in this period of crisis.

6. Conclusions

Some conflicts occur between managers and shareholders are due to ambiguous demarcation of the role they have each of the structures involved in corporate management.

Therefore, harmonize all these interests can't be made by itself but, as practice proves firms from countries with advanced market economy through an appropriate system of corporate governance which involves on the one hand, controlling insiders (employees and business managers) and, secondly, the outsiders (strategic investors, shareholders, unpaid, banks, state financial intermediaries, customers, etc.) undertaking the work and aims to prevent and avoid event conflicts of interest between different various stakeholders that can have harmful effects on company performance will be formed and, in general, the whole business community.

leobadea@yahoo.com

valu_radu@yahoo.com

Abstract

Modern analysis of strategic interactions through game theory has allowed to make some concepts clear. The equilibrium cannot be explained by the process of behaviour study. Each firm should guess the choice of the other firm, just like in a game of type "scissors-leaves-stone". The game theory eliminates this arbitrage showing that people act rationally, making decisions strictly individually. Three elements are taken into account: players, strategies and results. The two firms are the two players, the gains are the profits of the two firms and the strategies are represented by the product amount the two firms can produce. Within the present paper, an algebraic model will be developed which is in condition to offer to the interested ones a new perspective on (1) how the interaction between firms in a Stackelberg model can be studied and, (2) the way this framework can be extended to a talking about getting into an industry.

Key words: globalization, economic integration, competitive advantage, cluster, regional development.

J.E.L. classification: C38, C69

1. Introduction

The plus value of the present paper comes from two different sources: (1) the development of a framework to offer a different way to explain a simple solution to Stackelberg mathematical model. The same framework can allow a discussion with regard to getting into an industry – a subject which usually needs a fair value of sophisticated techniques. (2) The article

achieves this thing in an algebraic framework which is to be accessible to all those interested.

The oligopol is a market structure characterized by a limited number of firms which makes the researchers to approach this structure from the perspective of entry barriers. Due to this thing, the oligopol will gain benefits on long terms because the new firms are prevented from getting onto the market (e.i. automotive, steel, chemical etc. Industry). The causes of entry barriers are natural and legal.

The firms' behaviour is in connection with their position on the market which has to be protected against the potential competitors. The measures taken in this situation are strategic. The threat of a prices war or of a market flood with goods, when the new supplier does not succeed in getting onto the market, is another choice.

The oligopol is characterized by non-cooperant situations among firms, where from the interest for the mathematical modelling of non-cooperant game theory. The firms can promote two strategies:

competition by quality: oligopol of Cournot and Stackelberg type;

competition by price: oligopol of Bertrand and Edgeworth type.

The present paper is not meant to replace the presentations from the contemporary books (Carlton and Perloff (1994), Mansfield (1997), Varian (1996), Schotter (1997), Eaton and Eaton (1995), Salvatore (1997)). However, it proposes to inform and improve the way the Stackelberg model can be explained, the Stackelberg model being a sequel of Cournot model which takes heed of the asymmetric behaviour of two firms. Moreover, the paradigm developed in the paper can be extended to a general talking

about different ways of a firm to get onto market from the perspective of the new more and more difficult economical conditions. The talking with regard to the entry can be motivated by emphasizing the institutional decision factors or governmental regulations with regard to providing information which can decide if the competition between firms is simultaneous or successive. For example, a firm can possess a licence that allows it to get into industry first, whilst another firm can get into industry only after the first firm's license expiry. The Cournot model is characterized by the symmetric model of firms, meaning that both firms accept to have the same proportion on the market, they are interchangeable.

2. The models analyzed

2.1. Cournot Model of Oligopoly

Two firms that produce an homogeneous product are taken into account, in quantities q_1 and q_2 and with identical functions: $C_i(q_i)$.

Total production is:

$$Q = q_1 + q_2$$

The model assumptions are:

- I_1^C
- the request is pure and perfect;
 - the function of global request is monotone-decreasing and known before:
 $Q = Q(P)$;
 - the price distribution is known for each quantity offered by the market:

$$P = P(Q) = P(q_1 + q_2);$$

- I_2^C
- the output quantity produced represents a strategic variable;
 - the markets are up to mature markets where a producer cannot follow a price policy different from that of competitors, the customers being used to the existant various prices. An example in this direction is the automotive industry where each customer appreciates the

price of a automobile function on the category;

- I_3^C
- the product is perfectly homogeneous, meaning perfect interchangeable;

- I_4^C
- each firm's target is its profit maximizing, adjusting itself to market conditions function on the quantity that each of them gets on the market.

The maximizing program of Firm 1 is:

$$\begin{aligned} & \text{Max } \Pi_1(q_1, q_2), \\ \Pi_1(q_1, q_2) &= q_1 \cdot P(Q) - C_1(q_1) = q_1 \cdot P \\ & (q_1 + q_2) - C_1(q_1) \end{aligned}$$

The Firm 1 profit depends on the quantity produced by Firm 2. In order to make a good decision, Firm 1 must forecast the production decision of Firm 2.

According to the same reasoning, the maximizing program of Firm 2 works:

$$\begin{aligned} & \text{Max } \Pi_2(q_1, q_2), \\ \Pi_2(q_1, q_2) &= q_2 \cdot P(Q) - C_2(q_2) = q_2 \cdot P \\ & (q_1 + q_2) - C_2(q_2) \end{aligned}$$

In order to determine the equilibrium, each enterprise will maximize the profit for a production level given to the competitor. The equilibrium will check up on the conditions:

partial derivatives of first order must be null:

$$\frac{\delta \Pi_1(q_1 + q_2)}{\delta q_1} = \frac{\delta P(q_1 + q_2)}{\delta q_1} \cdot q_1 +$$

$$P(q_1 + q_2) - \frac{\delta C_1(q_1)}{\delta q_1} = 0$$

$$\frac{\delta \Pi_2(q_1 + q_2)}{\delta q_2} = \frac{\delta P(q_1 + q_2)}{\delta q_2} \cdot q_2 +$$

$$P(q_1 + q_2) - \frac{\delta C_2(q_2)}{\delta q_2} = 0$$

partial derivatives of the second order must be negative:

$$\frac{\delta^2 \Pi}{\delta q_i^2} \leq 0$$

The conditions of first order express the optimum production of Firm 1 function on the anticipation in choice made by Firm 2. These restrictions form the reaction function

of the firm which defines the firm's reaction deferring to the different conjunctures with regard to the possible choice of the other firm. So, for each firm the reaction function is written as following:

$$\frac{\delta P(q_1 + q_2)}{\delta q_1} \cdot q_1 + P(q_1 + q_2) =$$

$$\frac{\delta C_1(q_1)}{\delta q_1} \Rightarrow q_1 = R_1(q_2)$$

$$\frac{\delta P(q_1 + q_2)}{\delta q_2} \cdot q_2 + P(q_1 + q_2) =$$

$$\frac{\delta C_2(q_2)}{\delta q_2} \Rightarrow q_2 = R_2(q_1)$$

Functions $R_1(q_2)$ and $R_2(q_1)$ represent the functions of the best answer to the quantity offered by the other firm. The equilibrium is a particular case of these reaction functions. Thus, the first firm will determine the quantity that maximize its profit function on its costs, the second one, knowing the requirement, will determine the quantity to offer dependent on the quantity offered by the first firm. This will have an impact on the reaction function of the first firm which will have to adjust the offered quantity.

In order to find the equilibrium, q_2 has to be replaced through reaction function of Firm 2 which depends on q_1 :

$$q_1 = R_1(R_2(q_1)) \rightarrow q_1^*$$

Then, q_1^* is replaced function on reaction function of Firm 2 and q_2^* is found.

The equilibrium (q_1^* , q_2^*) is a Cournot – Nash equilibrium. Most often the couple (Q^*, P^*) is represented by

$$Q^* = q_1^* + q_2^* \text{ and } P^* = p(q_1^* + q_2^*)$$

The Cournot model allows to explain the equilibrium existence, starting from the adjusting process of a firm to another. For the beginning, just one firm is considered on the market to establish the quantity level which maximizes its profit and then, the second firm enters the market. It is assumed that the quantity choose produced by Firm 1 is known and Firm 2 will adjust itself to this situation, and will establish the quantity considered optimum to maximize its profit.

Firm 1 will react to what Firm 2 will do. It results a process of adjusting process in several stages. Each firm will observe and study the behaviour of the other firm.

2.2. The Stackelberg Model

Consider two firms I_1 și I_2 that produce quantities q_1 și q_2 with:

$$Q = q_1 + q_2$$

And identical cost functions: $C_i(q_i)$

The assumptions of the model are:

I_1^S – the competition is pure and perfect (consumers atomicity);

- the global request function is monotone-decreasing and known in advance, $Q = Q(P)$; the prices for each offered quantity are known.

The reversed request function is $P = P(Q)$.

I_2^S – the strategic variable for each firm on the market is the output quantity produced;

I_3^S – the product is perfectly homogeneous, and so, perfectly interchangeable;

I_4^S – each firm has as target the maximizing of its price;

I_5^S – Each "leader" holds a complete information with regard to the reaction curve of the other firm. The "follower" firm will seek to maximize its profit considering the situation created by the "leader" firm.

The working mechanism of the model is the following:

The "leader" firm is active while the "follower" firm is passive on the market. The leader will choose, first, its production level and then, it will establish the quantity that determines its profit maximizing, considering the quantity the follower firm will choose as reaction to its own choice. The leader assumes that the "follower" will want to maximize the profit, but he will accept the leader production choice. This will allow the leader to know in advance the "follower's" production and will take it into consideration when establishing its own level of production.

The target of each firm is to maximize its profit function on the quantity it chooses to sell on the market. The choosing of production level is made in a non-cooperant manner. The maximizing programs are as follows:

$$\begin{aligned} \text{Max } \Pi_1(q_1, q_2); \Pi_1(q_1, q_2) &= q_1 \cdot P(Q) - \\ C_1(q_1) &= q_1 \cdot P(q_1 + q_2) - C_1(q_1) \end{aligned}$$

$$\begin{aligned} \text{Max } \Pi_2(q_1, q_2); \Pi_2(q_1, q_2) &= q_2 \cdot P(Q) - \\ C_2(q_2) &= q_2 \cdot P(q_1 + q_2) - C_2(q_2) \end{aligned}$$

In order to calculate the equilibrium, the reaction function of the "follower" must be calculated. The leader firm is maximizing its profit by knowing the "follower" firm's reaction:

$$\frac{\partial \Pi_2(q_1, q_2)}{\partial q_2} = 0$$

It results:

$$\frac{\partial P(q_1 + q_2)}{\partial q_2} \cdot q_2 + P(q_1 + q_2) -$$

$$\frac{\partial C_2(q_2)}{\partial q_2} = 0$$

or other represented:

$$\frac{\partial P(q_1 + q_2)}{\partial q_2} \cdot q_2 + P(q_1 + q_2) = \frac{\partial C_2(q_2)}{\partial q_2}$$

The reaction function for the "follower" firm is:

$$q_2 = R_2(q_1)$$

Knowing the reaction function of the "follower" firm, it has to maximize the "leader" firm's profit:

$$\begin{aligned} \Pi_1(q_1, q_2) &= P(Q) \times q_1 - C_1 \times (q_1) = \\ &P(q_1 + R_2(q_1)) \times q_1 - C_1(q_1) \end{aligned}$$

This expression can be used to draw the izoprofit curves which are composed of all points (q1,q2) that reach the same profit level. The curves represent combinations of q1 and q2 which provide a constant level of profit for the "follower".

Maximizing the profit for Firm 1 is ensured by relation:

$$\frac{\partial \Pi_1(q_1, R_2(q_1))}{\partial q_1} = 0$$

Computing, the above relation becomes:

$$\frac{\partial P(q_1 + R_2(q_1))}{\partial q_1} \times \left(1 + \frac{\partial R_2(q_1)}{\partial q_1}\right) \times q_1 +$$

$$P(q_1 + R_2(q_1)) - \frac{\partial C_1(q_1)}{\partial q_1} = 0$$

$$\frac{\partial P(q_1 + R_2(q_1))}{\partial q_1} \times \left(1 + \frac{\partial R_2(q_1)}{\partial q_1}\right) \times q_1 +$$

$$P(q_1 + R_2(q_1)) = \frac{\partial C_1(q_1)}{\partial q_1}$$

Thus, q_1^* will be directly obtained

The answer of the "follower":

–introducing q_1^* in the reaction

function of the „follower” q_2^* is obtained;

–the market equilibrium is one of Stackelberg type (Q^* , P^*), with:

$$Q^* = q_1^* + q_2^* \text{ și } P^* = P(q_1^* + q_2^*)$$

The profit curves represent the set of combinations q_1 și q_2 which determines the same profit level. $\Pi = f(q_1, q_2)$.

3. Dixit-Spence Model

The Stackelberg model from previous section may be used as a starting point to introduce the idea of entry discouragement. Obviously, the first strategic variable as well as the output quantity produced by the asymmetrical behaviour are not enough to discourage the entry, because the residual requirement is not enough for a "follower" to enter the market and to make profit. So, the question arises – what should an existant firm do so that to warn other firms that want to enter the market?

Usually, the first model to introduce is Bain-Modigliani-Sylos-Labini. In the first stage, it is chosen the firm that gets out of the market even after its product entry. In the second stage, the firm decides upon the getting out way from the market. According to the BMS-L model, this getting out way is the same with that one the firm decided to use before coming back. However as we know the BMS-L model is not subgame perfect since once entry has occurred it is not profitable to produce the preentry output but

rather accommodate entry and behave as a Cournot duopolist.

For a detailed analyse of this model, it is necessary to use the ideas of Schotter (1996, pp. 409-11). The threat of expanding output to the point where entry is not profitable for the entrant and maintaining that output even if entry occurs is a non-credible threat.

So, what would it be a credible threat? In this situation the Dixit-Spencer model is needed.

As everybody knows, in case of Dixit-Spence model, the firms should invest in capacity and technology in order to hold a great concurential power, even more than in case of Cournot standard model or of Stackelberg duopol.

The development of this excess of capacity can determine the production increase from the moment of entry, which would ensure a perfect equilibrium to that firm which would want it to happen.

In the first stage, the traditional model Dixit-Spence refers to those decision taken with regard to the firm capacity when the entry on the market is considered. In the second stage, the firm chooses the quantity it will produce, followed by the obtained potential after entering and the decision to enter or not on the market. Thus, the firm, during the third stage will know how to answer to the market oscillations by adjusting its own production.

Let's assume that a firm chooses a production capacity of Q^* , so that for each output less than Q^* , the firm to be able to produce at the level of zero marginal cost like before. But for each quantity bigger than Q^* , the cost per unit becomes $\frac{1}{4}$. For a firm wishing to entry the market the cost per unit is $\frac{1}{4}$ because there are not clear information about the capacity size of the real production. So, the entry cost function is:

$$C_p = 0 \text{ for } q \leq Q^*$$

$$C_p = (1/4)q \text{ for } q > Q^*.$$

Having simple requirement of $C=1-Q$. The first question is – how much is the output if the input proves to be unprofitable? The answer is simple – the established price must be equal to medium cost. At this moment, the firm must wait a potential entry if it does not get a zero profit. Because C_p is

of $\frac{1}{4}$, fixing a price is equal to the medium cost, for that firm to be efficient it is needed a capacity of $\frac{3}{4}$ unit. The incumbent firm should install capacity of $\frac{3}{4}$ unit but produce its monopoly output of $\frac{1}{2}$. Confronted with this capacity of $\frac{3}{4}$ unit, the entry becomes nonprofitable, because in case the firm that gets this market ratio does not produce $\frac{3}{4}$, than, the residual requirement is $C = \frac{1}{4} - Q$ and even the intention to get out from this residual market is 0.

The incumbent firm can now costlessly expand output till $\frac{3}{4}$ unit making such entry unprofitable. Thus in this model the incumbent firm installs just enough capacity that will make entry unprofitable and then in the equilibrium of this game, entry does not occur and the incumbent firm continues to enjoy monopoly profit. If the incumbent does not have installed capacity then it cannot deter entry by a potential entrant. In this case produces its optimal output as the Stackelberg leader which would be $\frac{3}{8}$ and that of the follower would be $\frac{3}{16}$.

4. Manipulating different entry ways

We can speak about a large variety of models with regard to a firm entry on the market. How is this idea of different entry ways motivated? Aoki and Prusa (1997) point out that institutional factors and governmental regulations of a country can determine, by the information provided, major changes of the game by detrmining an unloyal competition.

In the U.S. context then a firm with a patent may enter an industry first to be followed by others when the patent expires. But in the Japanese context since the patent is thrown open to a firm's rivals before it is granted to a firm, it is not inconceivable to think of more than one firm entering a market simultaneously to be followed by others at a later date. Such differences in patent law could explain how there could be different entry sequences into a market.

Other said, I can develop these problems such as:

(1) we assume firm 1 that wishes to move and decides to get out; firms 2 and 3 observe firm 1 intention and will try the same thing. We calculate the outputs produced by each firm.

(2) we assume that firms 1 and 2 act as Cournot duopol and decide upon their production. The firm 3 observe both firms tend to get out an makes a decision on its production. We calculate the output of each firm.

As for the problem (1): when firm 1 decided to get out from the market, it behaves just like part of a monopoly and, consequently, it influences the entire market $C = 1 - Q$ and chooses a getting out of $\frac{1}{2}$ monopoly. So, firms 2 and 3 face a new curve of form $C = \frac{1}{2} - Q$ on the new market. They produce $\frac{1}{3} * \frac{1}{2} = \frac{1}{6}$ each.

Similarly, for the second problem (2), firms 1 and 2 are duopol and each of them will produce $2 * \frac{1}{3} = \frac{2}{3}$ from the market. So, in this situation, firm 3 faces a market requirement $C = \frac{1}{3} - Q$. When firm 3 decides to get out of the market it can act as a monopolist and chooses the monopoly type getting out in the residual part of the market, which is $\frac{1}{2} * \frac{1}{3} = \frac{1}{6}$. Again, it is easy to check if this getting out makes the Stackelberg model.

The most speciality books offer an adequate cover of the monopoly models as well as the oligopol type, such as Cournot or Stackleberg. However, we do not find many information about firms' entry models but about firms' entry discouragement, as Dixit-Spence model does. Thus, a simple discussion about discouraging firms when enter the market is a plus of the lectures approaching this subject.

5. Conclusion

In this paper I have provided a simple algebraic framework for teaching the Stackelberg model where firms move sequentially instead of simultaneously. This framework provides a different way of thinking about the Stackelberg model. The framework can be extended to undertake a discussion of various modes of entry.

Moreover the model has the added advantage that it takes topics which can be technically sophisticated and provides an intuitive and computationally simple way of dealing with them.

Opinions on the Importance of Knowledge Management

Curețeanu Radu Silviu

Abstract

Many practices attempting to manage individual and corporate learning have over time converged into what is now labelled 'knowledge management'. A number of disciplines have been involved in this evolution, ranging from psychology to management. This diversity has culminated in the development of a range of terms such as 'the learning organization', 'intellectual capital management', 'intellectual asset management' and 'knowledge management'.

From these beginnings it is easy to conclude that the modern conceptualization of knowledge management is an umbrella for capturing a range of organizational concerns. Irrespective of the precise terminology, there fortunately is common understanding that knowledge management encapsulates a more organic and holistic way of understanding and leveraging people within work processes for business benefit.

Key words: knowledge management, competitive advantage, innovation.

J.E.L. classification: M10

1. Introduction

While knowledge management has become rather fashionable in the 1990s, recognition of its importance precedes current-day interest. Edith Penrose in analysing the economics of the firm commented on the difficulty of managing the process: 'Economists have, of course, always recognized the dominant role that increasingly knowledge plays in economic processes, but have, for the most part, found the whole subject of knowledge too slippery

to handle' [1]. Herbert A Simon insightfully declared that knowledge is more than technology: 'In the period ahead of us, more important than advances in computer design will be the advances we can make in our understanding of human information processing, of thinking, problem solving, and decision making . . .' [2].

Moreover, interest in knowledge management was not just confined solely within the domain of academic discourse but alluded much more popularly, as the quote from H. G. Wells highlights: An immense and ever-increasing wealth of knowledge is scattered about the world today; knowledge that would probably suffice to solve all the mighty difficulties of our age, but it is dispersed and unorganised. We need a sort of mental clearinghouse for the mind: a depot where knowledge and ideas are received, sorted, summarised, digested, clarified and compared [3].

2. Towards new approaches for competitive advantage

Scholars and observers from diverse perspectives, sociology, economics and management science, agree that managing knowledge is a fundamental driver of organizational progress in the modern business environment. Harvard sociologist, Bell [4] presented one of the earliest analyses of the changes that might accompany the increase in knowledge use. Stanford economist, Romer [5], published the first quantitatively rigorous treatment of how the use of knowledge affects economic growth. Management guru, Drucker [6], provided a historical perspective of how recent economic changes could be framed within a business context.

The trend over time has been for knowledge-based firms to move towards precognition and adaptation. This is in stark contrast to the traditional emphasis on optimization. This trend is amplified by two facilitating factors: speed and interconnection. All these elements intertwine for future organizational success. Speed, in the form of transmission of information and knowledge, quicker decision making and innovation cycles, together with interconnection of information systems, workers, organizations and economies, facilitates precognition and adaptation. Castells [7] summarizes the shift as follows: 'What characterises the current technological revolution is not the centrality of knowledge and information but the application of such knowledge and information to knowledge generation, information processing, communication devices, in a cumulative feedback loop between innovation and the uses of innovation.'

Companies are facing up to this new reality. The modern business economy does not favour organizational competencies that have provided historic business success. The new era demands new formats and new strategies, and managing learning and knowledge rests central within these.

3. Traditional concepts

Organizations exist because collaboration of resources can yield higher outcomes than an individual alone. Argyris and Schon [8] note that a collection of individuals becomes an organization when the individuals start to act for the good of the organization. The organizational collective is awarded identity by the actions of the individuals it comprises.

Henri Fayol, in the early twentieth century, was the founder of the administrative school of management. He divided the company into six functional departments: technical, commercial, financial, security, accounting and managerial. These divisions came about prior to modern thinking on marketing and sales. Fayol [9] was one of the first people to demonstrate the concept of an ultimate system of operation for an organization. At about the same time a German psychologist, Max Weber, developed a series of rules for efficient organization [10]. He proposed that

a hierarchy should be developed, and positions in that hierarchy should be awarded on merit. Additionally, he suggested that organizations should be divided into parts, with a clear specification for each part. Both of these theories have merit but are somewhat outdated, having been formulated in an era when the turbulence and turmoil we see daily in business today was virtually non-existent. A particular weakness in companies basing their structures on the edifice of these theories is that they become cast in an inflexible mould, finding it difficult to change in the face of external forces.

The business historian and analyst, Alfred D. Chandler, argued in the 1960s that the structure of an organization governs the effectiveness of its use of resources. Therefore company strategies should reflect not only the use of resources, but also the specific goals the company is trying to achieve. Igor Ansoff, the strategy theorist, built on this notion by suggesting that the use of resources was to be maximized prior to the matching of business opportunities with organizational resources [11]. In short, he believed in maximizing strengths and minimizing weaknesses. However, both these approaches produce a company with distinct strengths that are difficult to change if the market moves on (as it inevitably does). Some of Ansoff's later work focused on 'paralysis by analysis', showing such organizations to be too rigid and slow to adapt to change.

In the 1980s, Porter developed a framework for the analysis of competitive strategy [12]. It focused on the view of an organization as an entity driven by reactions to its external environment. Porter identified five forces relevant to company success or failure and suggested that strategy should be formulated by the organization to deal with these. The five forces are:

- The potential of new entrants to the market.
- The bargaining power of customers.
- The threat of substitute products.
- The bargaining power of suppliers.
- The activities of existing competitors.

Each factor can affect profitability, and this profitability determines what is the most effective and appropriate strategy. In later work, Porter linked internal, or corporate,

resources with the external environment by explicating the concept of the value chain. The value chain is the chain of business operations that the organization must control and configure to construct a coherent competitive strategy. It includes management of such things as such as logistics, marketing, production and sales, and support functions such as human resources and technical infrastructure. Porter argues that a firm gains competitive advantage by performing these value-chain activities more cheaply, more effectively or in a better way than the competition.

4. Developing knowledge management and learning as core competencies

It is the management of internal or corporate resources that with which we are most concerned. While market economic theory takes the view of scarcity of resources, organizational theory assumes that the same external resources are available to all. Therefore, only better internal resources can make a difference to achieving a competitive advantage over the competition, i.e. internal resources must perform better than the competition. Internal resources are assets such as the human resources or machinery belonging to a particular organization. These assets must perform its task more effectively than the competition.

Prahalad and Hamel [13] extend this view in defining the notion of core competencies, which are responsible for competitive advantage. Moreover, to build and sustain competitive advantage the core competencies must be difficult to imitate, non-substitutable, durable and non-transparent. Some of these core competencies are not independent – other factors come into play when you depart from the theoretical world and move into the real world: Itami [14] stated that irreversible assets were divided into tangible and intangible sources of profits; Collis [15] built on the work of others in identifying organizational capability as the firm's dynamic routines that enable it to generate continuous improvement in efficiency or effectiveness, and that it embodied the firm's tacit knowledge of how to initiate or respond to change. From this perspective, the organizational capability of managing knowledge and learning is deemed a core

competence.

It is in the science of developing core competencies that organizational learning and knowledge management is most intimately associated. In order for a resource to yield competitive advantage the firm must utilize it in a unique way, or have some unique knowledge about its function. A prime example of a company attaining a competitive advantage is the development of a new product that is patentable. Once patent protected, the product can produce a profit stream. If we look back at how that product was developed we can see that a systematic analysis of a market or a customer need produced the concept or design for that product. There are several systematic ways of generating such concepts or ideas in line with the customer's requirements. It is the basic premise of organizational learning that such insight or process is applied to other aspects of the organization's function in order to generate a better or more efficient way of operating. The process described in this example, at a theoretical level, can be described as the management of knowledge for marketplace advantage.

5. Conclusion

In sum, we can conclude that knowledge management is as a complex, multi-layered and multifaceted concept. This is demonstrated by the number of differing opinions about the essence of knowledge management, which is reflected by the fact that there is no universally agreed definition of knowledge management. Nevertheless, most agree it is something to do with the systematic management of knowledge to achieve business benefits. On the basis of the discussion, we propose that knowledge management is the coming together of organizational processes, information processing technologies, organizational strategies and culture for the enhanced management and leverage of human knowledge and learning to the benefit of the company. Knowledge management is not a separate management function or a separate process. Knowledge management consists of a set of cross-disciplinary organizational processes that seek the ongoing and continuous creation of new knowledge by leveraging the synergy of combining

information technologies, and the creative and innovative capacity of human beings. To bring about business benefits, knowledge management has to be aligned to the company's strategic thrust. Indeed, if knowledge management is a 'new' organizational paradigm, it is only so in the sense that attempts are now being made to systematically manage it.

Abstract

Emotional problems are the most common problems encountered in our century. If you ask someone which would be the biggest dissatisfaction in his life, probably the overwhelming majority of responses will revolve around relationships, communication difficulties, and the inability to resolve certain relational conflicts. Anxiety, panic attacks, addictions, obsessive or depressive tendencies, anger, can be added to the above list. By developing skills related to emotional intelligence, we can control these problems and we can turn them in our favor. It is an undeniable truth that emotional intelligence may facilitate our way to success in any field.

Key words: emotional intelligence, leader, organizational performance, labor quality.

J.E.L. classification: M 59

1. Introduction

The range of emotions felt increases with the age (at least during childhood and during the period between childhood and maturity). The lack of communication causes the onset of conflicts. The education of the emotions can lead to an improvement in the results of the scholars, of the students, and further in the career of the individuals. This education should begin as soon as possible in order to gain constructive emotional capacity. This is necessary because the rehabilitation of the emotional capacity is more difficult.

Through this paper we intend to analyze the importance of the emotional intelligence

in leadership. Firstly we will make a foray into the literature in the field of the emotional intelligence, identifying its origin, defining the concept, and presenting the components of the emotional intelligence. In the second part of the paper we will focus on analyzing how emotional intelligence guides the leader in the organization.

2. The Origin of the Concept. Definitions

The term "emotional intelligence" was for the first time used in a classical academic formula, in a doctoral thesis in the U.S.A in 1985 by Wayne Leon Payne, Ph.D. from Union Institute, Cincinnati. In his opinion the emotional intelligence is a skill that involves a creative relationship with feelings of fear, pain and desire. This doctoral dissertation introduced a new term which after 15 years was about to change the theories about leadership, about the manager's role or how he interacts with the people he leads.

The concept of "emotional intelligence" is published for the first time in the papers of John D. Mayer and Peter Salovey (1990, 1993). They are considered the parents of the new intelligence the emotional one. The above mentioned authors are the first authors who treated seriously the subject and defined for the psychological world the new term. Little publicized, the subject of their work is taken into account only in the medical world.

In 1995, "The Time" published the famous article "What's Your EQ?" signed by Daniel Goleman, a journalist at this newspaper, where over time he wrote articles about the

brain and human behavior. Emotional Intelligence became known after the publication of the book "Emotional Intelligence: Why it CAN matter More Than IQ " in 1995.

Although the term is relatively new the components of the concept, can be traced back to the statement of Socrates (470-399 BC) "Know yourself ", in the Bible, in both Old and New Testament "Do not do to others what you do not like" and "Love your neighbor as yourself" can be seen as elements of emotional intelligence.

Researches on emotional intelligence are relatively recent, debuting around the 90s. In the work of Mayer and Salovey (1990) the concept of emotional intelligence is defined as the ability to control the own emotions and feelings, the ability to differentiate between them, and the ability to use this information to guide the own way of thinking and actions. With this definition, the two authors wanted to highlight the positive interacting between emotion and thought.

Another important direction regarding the emotional intelligence is the one offered by Daniel Goleman. In his opinion the concept of emotional intelligence means:

- to be aware of what you feel and what others feel and to know what to do about it;
- to know how to discern what is right and wrong for you and to know how to pass from bad to good;
- to have emotional awareness, sensitivity and leadership capacity to help you to achieve the happiness.

David Goleman in "Emotional Intelligence in Leadership" shows the importance of the emotional intelligence in leadership claiming that "the primary responsibility of the leader is to induce positive feelings [...] creating resonance - a reservoir of positive elements"[2].

3. Components of the Emotional Intelligence

Analyzing the studies conducted over 25 years by Reuven Bar-On., emotional intelligence components are grouped as follows:

a) Intrapersonal appearance:

Awareness of own emotions - the ability to recognize own feelings;

Optimism (assertiveness) - the ability to express thoughts, beliefs, feelings, in a constructive manner;

Respect - account for yourself - the ability to respect and accept what is (at the basis) good;

Self-realization - the ability to get involved in the search for goals, goals that have a certain meaning and a specific meaning for you;

Interdependence - the ability to direct and control yourself in your own thoughts and actions, the ability to be free of emotional dependency.

b) Interpersonal aspect:

Empathy - the ability to be conscious, to understand and appreciate the feelings of others;

Interpersonal relationships - the ability to establish and maintain positive reciprocal interpersonal relationships;

Social responsibility - the ability to demonstrate your implication as a taxpayer and constructively member of the social group whom you belong or you have formed.

c) Adaptability

Problem-solving - the ability to be aware of the problems and to define problems in order to generate and implement potentially effective solutions;

Reality testing;

Flexibility - the ability to adjust your thoughts, emotions and behavior in order to change the situation and conditions.

d) Stress control:

Tolerance to stress - the ability to withstand stressful events and situations without you stumble and also the ability to cope actively and positively;

Impulse control - the ability to resist or postpone the impulsiveness and to chase the temptation which determines you to act in hurry.

e) General provision

Happiness - the ability to feel satisfied with your own life, to have fun alone and with others, to feel good;

Optimism - the ability to see the bright side of life, to maintain a positive attitude despite the adversities.

According to Goleman any individual can raise the own degree of emotional intelligence through education and exercises, but some components of emotional intelligence are treated as personality traits and therefore could not change during the life of the individual.

Currently, there is a disagreement whether the emotional intelligence is more an innate potential, or whether it represents a set of abilities, competencies or learned skills.

Daniel Goleman (1998) sustains that "unlike the degree of intelligence, which remains the same throughout life or the unchangeable personality, emotional intelligence competencies are based on the learned skills .

Emotional intelligence is the personal ability to identify emotions and to manage them in a effective way in relation to the personal goals (career, family, education etc). Its finality is to achieve our goals, with minimal inter and intra-personal conflicts.

The way each uses his emotional intelligence depends the success or failure on his career. Even if a person has sufficient knowledge and intelligent ideas, if he fails to manage his emotions and feelings, may face difficulties in trying to build relationships with others or a successful career. People with a high degree of self-discovery realize that their feelings affect both themselves and the others. Developing emotional intelligence allows valuing of the intellectual skills, of the creativity, ensuring success in both personal and professional domains.

Leaving aside the complicated definitions, the ability to be emotionally intelligent is found to be twice important as technical and intellectual skills. It is more difficult to understand what a person wants to express through a nonverbal code, especially if we take into account the introverted persons which have difficulties in expressing their inner states and becomes a real challenge to interpret them. In some areas, a gesture considered highly politeness is seen elsewhere as a terrible offense, every little detail has its significance. For example, the high thumb raised and the rest of the fist close is for Americans "OK", while in Brazil is perceived as an insult.

4. Emotional Intelligence. Managerial Competencies

In the second part of the paper we intend to highlight how the adjacent areas and competencies of emotional intelligence affect leadership within the organization.

As Goleman points out in his study *Emotional intelligence in leadership* the basic role of the leader is emotional, this basic dimension of management conducting to the success of the corporation [2].

The study explains why to use a management model based on emotional intelligence, and also provides ways for leaders to use their emotional intelligence.

This study shows that the actions of the leaders have a significant influence in stimulating people loyalty, enthusiasm and motivation.

The research that led to this model, is based on hundred interviews with managers at different levels of the company, employees, rectors from around the world on leadership issues. In this study Goleman presents a new class of leaders who lead using human relationships.

His work is an examination of how emotional intelligence affects the performance. The first part of the paper defines the parameters of emotional intelligence and leadership, followed by a study on the influence of these parameters on the efficiency of decision taken by leaders within the organization. The four parameters of emotional intelligence of the leader are: self-awareness, self-control, social consciousness, managing relationships.

The first two parameters refer to the skills and personal abilities of the leader, while the last two relate to social skills of the leader, meaning the manner in which they manage relationships

I. Self-Awareness

Emotional self - awareness. Leaders who have good emotional self awareness are able to talk openly about their emotions understanding how feelings affect them and how emotions affect their job performance.

Correct self-evaluation. Leaders with self-awareness know their strengths, their limits and the correct self-evaluation allow them to know when to ask for help.

Self-esteem. Confident leaders can assume difficult projects with a safety that makes them stand out in a group.

II. Self-control

Self-control. Leaders who posed a good emotional self-control, keep their calm under stress, in crisis situations, managing to guide the emotions and impulses in a positive direction.

Transparency. Transparent leaders are able to recognize open when they made a mistake or a wrong act.

Adaptability. Adaptable leaders are those who adapt to the permanent changes encountered in the internal and external environment of the organization proofing flexibility when dealing with new data or events.

Ambition. Ambitious leaders are driven by the desire to overcome their record, they impose themselves challenging but achievable targets.

Initiative. Efficient leaders, meaning those who have the necessary resources to control the driven organization, excel in matters of leadership.

Optimism. In the opinion of the optimistic leader any obstacles are rather opportunities than threats.

III. Social consciousness

Empathy. Empathetic leaders are able to understand different people with different training, or from different cultures. These leaders also listen carefully and understand the point of view of others.

Organizational Consciousness. A leader with a strong social conscience will be able to detect power relations, unwritten rules that operate within human groups under his coordination.

Solicitude. Leaders who master this competence shall be made available to others when needed, carefully observe customer satisfaction to ensure that they get what they want.

IV. Managing relationships

Inspiration. Inspired leaders are able to formulate a mission in a manner that will determinate the group to perceive their work more exciting.

Influence. Leaders with power of influence have the ability to persuade key people or to find the appropriate people necessary for certain activities.

The management of the conflicts. Leaders who have this competency are able to listen the point of view of all parties and then to find a common denominator to gather all sides.

Teamwork and collaboration. Leaders who spend time forming and strengthening close relationships, build the spirit and the identity of the group.

No matter what leaders aim - to create strategies or to mobilize teams to act-their success depends on how they act. Trying to explain the effectiveness of our real leaders we will find that they are using emotions. Best leaders are different from others because they understand the important role played by emotions at the workplace and their impact on tangible aspects (eg. business results) and intangible aspects (morale, motivation, people dedication).

5. Moods and Organizational Performance

In any human group, the leader has the ability to influence the emotions of all. If human emotions are channeled to enthusiasm, performance is born, if the leader awakes in people anxiety, they will lose the efficiency, disciples waiting for empathy from leaders.

Emotions and moods have real consequences on carrying out activities within the organization. When people are in a good mood, they see the positive side of the situation contributing to the success of the business but if they are indisposed they stop on the negative side. Negative emotions (anger, anxiety, feelings of worthlessness) seriously affect the climate work.

When people feel good do their best to achieve the objectives of their organization, are more creative. For example, optimistic insurance agents are able to insist more, despite the denials, than their pessimistic colleagues and therefore have better sales.

The success of the leader depends on its attitude to forward the group an enthusiastic and cooperative mood.

6. Concluding Remarks

The old model of leadership had a functional purpose, not related to emotional or personal dimension, people were considered to be interchangeable parts. Such impersonal management records today more and more failures.

Resonant leaders could be a way to replace the old style of leadership, embodied by authoritarian old-fashioned figures.

Representatives of the new style of leadership, excel in the field of human relations, the single quality which remains indispensable in the permanent changing business environment.

Excellent leadership is seen through the mergers of corporations across the national borders, by redefining the connection networks of clients and suppliers by excusing the whole layers of managers.

Gifted with emotional intelligence, leaders know when to work, when to be visionary, when to listen and when to dominate. This type of leadership creates a flexible climate, ultimately leading to the creation of the added value.

Economic Sizing Stock Production in the Economic Entities

Cușu Dorinela

„Ovidius” University of Constanța, Faculty of Economic Sciences
cusudorinela@yahoo.com

Abstract

The stock production is the amount of resources that is the result of a request and an offer of a way of organizing the supply activity with raw materials and must ensure the necessary materials in the production process between two consecutive supplies activity. His need is determined by the inconsistency in time and space of the production and consumption of resources, by the existence of different rates of production (consumption), by some uncertainties regarding the supply activity. These are arguments that impose within the economic entities the existence of resource stocks materials, such as safety stock – in order to eliminate the uncertainties regarding the consumption process, the quantities delivered and the time of delivery or speculative stocks – in order to eliminate negative influences of rising prices.

Key words: current stock, stock security, stock preparation and conditioning, seasonal stock

J.E.L. classification: M 19

1. Introduction

Economic agents form their stocks of material and products in order: to ensure uninterrupted supply of sub-units of consumption, satisfying customer requests in strict accordance with the claims they issue, to ensure optimal conditions of operation of each business unit.

Owning stocks require specially designed and equipped spaces, storage costs expenses with the insurance of the stocks, etc.

Stocks for production include: basic and auxiliary raw materials, components and subassemblies of the future finished product, materials and spare parts, packaging and packaging materials.

2. Main categories of the stock production within the economic entities

Stocks are the quantities of material that accumulates in warehouses and storerooms of the economic units in a certain volume and structure for a period of time, with a particular purpose.

Stock are actually the result of supply and trading activities. It is recommended that each economic unit calculates a series of stock materials such as:

- current stock
- safety stock
- stock for preparation or conditioning stock
- seasonal stock

2.1. The current stock

The current stock is the amount of raw materials required for continuous production process between two successive supplies activities with raw materials and materials from the supplier. Current stock size is determined by the following formula:

$S_c = C_{mz} * T$, where:

S_c = current stock

C_{mz} = average daily consumption of raw materials and materials; average daily consumption is determined by dividing the actual need for materials and raw materials to meet production program at the number of days during that program.

T = the average time between two consecutive provisions (in days), this time is provided in the supply contracts signed with the suppliers.

2.2. The safety stock

The safety stock is the quantity of material that must exist in the unit in order to be used in the production process when current stock is depleted, and there are delays in its integration due to disturbances in the deliveries from suppliers, or due to a consumption growth rate during the period beyond estimated limits.

Safety stock is an additional accumulation of material in stock and therefore a financial asset fund involved in their purchase.

This type of stock is provided for setting up basic raw materials, materials that are a condition for the continuity of the productive activities of the enterprise and the provider is located at a relatively large distance from the client that does not solve supply problems rapidly.

The safety stock is also used in the retail sales activity in order to honor promptly the demands of the clients. In determining this stock are taken into account the time for several activities like: the time for making on order, the time for transportation and the time related to activities such as unloading, receiving and storing materials. The formula for calculating the safety stock is:

$$S_{sig} = C_{mz} (t_1 + t_2 + t_3), \text{ where:}$$

Ssig = safety stock

Cmz = average daily consumption of raw materials and materials

t1 = time to establish connection with suppliers and preparing by them a lot of delivery

t2 = time to transport materials from the supplier to the beneficiary

t3 = time to unloading, receiving and storing materials

2.3 Stock for preparation or conditioning stock

The stock for preparation or conditioning is the amount of material accumulated and stationed for a period in dedicated facilities, necessary to those economic units where the materials must be subjected to prior preparation activities before coming into the production process.

Usually preparation operations are performed at the supplier, so that the beneficiary can use the materials immediately, but there are cases in which these activities through the contract are assigned to the consumer or although the activities have been performed at the provider, during transportation the physico-chemical parameters were not maintained.

At the end of the preparation activities the materials are included in the current stock in order to be used for its intended consumer set. The formula for calculating the stock for preparation is the following:

$$S_{pr} = C_{mz} * t_{pr}, \text{ where:}$$

Spr = stock for preparation or conditioning stock

Cmz = average daily consumption of raw materials and materials

tpr = time to prepare the material

2.4. Seasonal stock

Seasonal stock is the amount of material that accumulates in the deposits of the units in order to ensure the continuity of the production process in case of seasonal conditions of production, supply or transportation.

For example the economic units that use raw materials such as iron ores, nonferrous metals, coal, limestone, wood imports, their stocks are seasonal because the shipping with these materials is interrupted during the winter. That is why these stocks are also called winter stocks. The formula for calculating this type of stock is the following:

$$S_{sez} = C_{mz} * t_i, \text{ where:}$$

Ssez = seasonal stock

Cmz = average daily consumption of raw materials and materials

ti = time of interruption (in days) in the supply of this material

Besides these types of stocks are distinguished other categories of stock such as:

- strategic stocks of conjecture or speculative stocks are the material resources acquired when it is considered that the

acquisition price of these materials is most favorable and in future it will have a tendency to increase

- stocks in course of transportation represents the amount of material found in means of transport during their travel from providers to beneficiaries.
- internal transport stock is the amount of material that accumulates in manufacturing workshops in order to cover claims for consumption during the release and transportation period of materials from the central warehouse to consumer's destinations.

Stock production is expressed in:

- natural units (tones, kg, paces) - this expression serves to estimate the physical potential production, of works or services that can be realized with the stoked quantity;
- values (ROL thousand, mil. etc); this expression allows through summarizing to express the total stock;
- in days: this expression outlines the period for which the physical stock covers up the consumer's demand;

3. Economic sizing stock production in the economic entities

Economic sizing stock is an act of great importance for improving the financial situation of units from different industries.

In the following part of the paper I will illustrate how to determine the current stock in a economic entity from the milling and bakery industry.

In determining the current stock (Scr) it can be used several ways, depending on the purpose and elements to be taken into account. For example the static method is based on the effective ranges between supplies from providers in the previous period (Ief) and the actual quantities of materials into warehouses (Qefi).

The formula used to determine the current stock in physical expression is:

$$Scr = Cmz * I, \text{ where:}$$

Sc=current stock

Cmz=average daily consumption of raw materials and materials; average daily consumption is determined by dividing the actual need for materials and raw materials to

meet production program at the number of days during that program.

I = the average time between two consecutive provisions (in days), this time is provided in the supply contracts signed with the suppliers.

Average daily consumption is calculated by dividing the necessary materials to meet production program (Npl) at the period for which this is taken into account.

$$Cmz = Npl / \text{reporting period} \text{ or } Cmz = Npl / 360$$

The average interval between the two supplies is determined using the weighted arithmetic average:

$$I = \frac{\sum qefi \times Iefi}{\sum qefi}$$

Qefi = effective quantity entered the warehouse of the company;

Iefi = effective range between two successive entries;

Σ qefi = sum of actual quantities.

In order to analyze the evolution of the current stock of the main resource needed for the manufacture of bakery products - flour, during a month I will use the flour sheet store. The flour sheet store is used to determine the planned need of flour (Npl). In this direction, table no.1 presents the manufactured production quantities (Qp) and the consumption regulations (Nc) for flour.

Table no.1

Material	Flour type 650
Nc/1000kg finished product	785kg
Qp	80.000 kg
Np	62,8 mil kg
Cmz	174.444 kg

Table no. 2 - Flour type 650 sheet store

Date	Amount entered	Amount outstanding	Final stock	Date	Amount entered	Amount outstanding	Final stock
01.05	150		150	17.05		55	67
02.05			150	18.05			67
03.05	100	65	185	19.05	150	140	77
04.05			185	20.05			77
05.05	95	85	195	21.05			77
06.05			195	22.05	200	170	107
07.05			195	23.05			107
08.05	100	103	192	24.05	165	170	102
09.05	80	45	227	25.05	100	120	82
10.05			227	26.05			82
11.05			227	27.05			82
12.05	220	300	147	28.05	300	315	67
13.05			147	29.05	200	205	62
14.05			147	30.05	50	75	37
15.05	90	115	122	31.05			37
16.05			122				

The interval between two successive supplies (I) at the resource-flour type 650 is determined (based on the sheet store) using the following formula:

$$I = \frac{\sum qefi \times Iefi}{\sum qefi} = \frac{2060t}{2000t} = 1,03days$$

$$\sum qefi \times Iefi = 150 \times 1 + 100 \times 1 + 95 \times 2 + 100 \times 0 + 80 \times 2 + 220 \times 2 + 90 \times 3 + 150 \times 2 + 200 \times 1 + 165 \times 0 + 100 \times 2 + 300 \times 0 + 200 \times 0 + 50 \times 1 = 2060t$$

$$\sum qefi = 150 + 100 + 95 + 100 + 80 + 220 + 90 + 150 + 200 + 165 + 100 + 300 + 200 + 50 = 2000t$$

Knowing the necessary planned (Npl) for flour type 650 which is 62.8 million kg / year and the interval between two successive supplies (I), which is 1.03 days, it can be determined the current stock in the month under review, with the following relationship:

$$Scr = Cmz \times i = \frac{Np}{360} \times 1.03 = \frac{62800t}{360} \times 1.03 = 180t$$

As shown in the sheet store there is a situation not very satisfactory regarding the meal entries. At the beginning of the month there was an inflow of 150t of flour type 650, amount that was situated below the current stock (which was 180t). But in day 3 - due to inputs (100t) more than the actual stock consumption (65t) the effective stock is above the current one: with 5t at 03.05., with 15t at 05.05 and 47t at 09.05. Overstocks continued until day 11 – inclusive, after that due to inputs lower than actual outputs the

company obtained on effective stock under the current stock.

Overstocks existing at several material resources, is a result of the improper material inputs in relation with the outputs for consumption. Regarding the existence of overstocks for 5 days, drew a series of negative phenomena: high maintenance, storage, conservation stocks, low quality of the material stored for a long time, immobilization of financial funds.

This situation affects the overall activity of the company, resulting the decrease of the efficiency and profitability of the business. Thus, these funds could be used in other more productive purposes or investments, leading ultimately to the development of the company activity.

4. Conclusions

The stock production is the amount of resources that is the result of a request and an offer of a way of organizing the supply activity with raw materials and must ensure the necessary materials in the production process between two consecutive supplies activity.

Economic agents form their stocks of material and products in order: to ensure uninterrupted supply of sub-units of consumption, satisfying customer requests in strict accordance with the claims they issue, to ensure optimal conditions of operation of each business unit.

Stocks for production include: basic and auxiliary raw materials, components and subassemblies of the future finished product, materials and spare parts, packaging and packaging materials.

Stock are actually the result of supply and trading activities. It is recommended that each economic unit calculates a series of stock materials such as: current stock, safety stock, stock for preparation or conditioning stock, seasonal stock

Economic sizing stock is an act of great importance for improving the financial situation of units from different industries.

Goods Distribution and Logistics in the Current Economic and Financial Crisis

Dan Gheorghe

"Ovidius" University of Constanta, Faculty of Economic Sciences

secretariat@traian-sa.com

Abstract

This article aims at assessing the impact of financial crisis and economic recession on goods distribution and logistics, the consumption behaviour of the behavioural changes made by the members of marketing channels. There have been observed the reactions of economic units, the strategies and tactics used in an attempt to maintain the level of sales, as well as the preparation of organizational and logistic capacities in order to make survival possible in this hostile environment.

Key words: financial crisis, decline in purchasing power, investment sluggishness, impulse buying decision for low value products, moderation buying decision.

J.E.L. classification: M31

1. Introduction

The conventional relationship checked over time between unemployment rate and inflation rate has been a concern to avoid economic overheating which leads to generating financial imbalance in the economy.

The financial overheating generated by the hanging up of rational measures in granting consumer credits, as well as a financing explosion through the use of some toxic products in credit facilities and giving guarantees have led to the creation of a speculative balloon "irrational exuberance" which finally generated the financial crisis through the emptying of capital reserves.

The lack of financial resources, through decimating the capital of financial institutions, the use of toxic financial tools have led to the economic decline both at the level of financial institutions (the bankruptcy

of some commercial and investment banks) and at the level of companies which carry on their activities in various economic fields.

Therefore, there has been a decrease of confidence in financial institutions, as well as the entrepreneurs' indifference who, due to a lack of crediting, cannot meet the conditions of running their businesses, financial blockade, being unable to restart the business cycle.

In a declining economy, regaining the appetite for business is crucial, since this decline is characterized by the lack of financial funds, restriction in granting credits, entrepreneurs entering the market, most of them being declared insolvent, stagnation or even suspension of activities.

Restoring confidence by starting off the economic mechanisms will require the use of a package of measures ready to generate demand and increase business confidence. These measures alone cannot change the situation, but we can also mention:

- The infusion of capital in the financial system for recapitalization;
- The system of financial stimulation of economic units in using economic capacities, the easy access to getting credits and the elimination of their distrust or indifference;
- The stimulation and expanding of public, local and central expenses favouring durable projects on urban and rural infrastructure, road and highway networks, and other systems which could stimulate production, distribution, and especially provide for the increase in demand and the stimulation of expenses;
- Creating new jobs and falling unemployment, using available or downsized labour force as a result of recession and bankruptcy of economic units;
- An effective control of the inflation rate to prevent economic overheating. The objective of the central banks is to maintain a

refinancing interest rate with a view to stimulating investments and providing for rational measures in economy, without creating speculative balloons.

During economic crisis, with its main component, i.e. the financial crisis, a contraction of the activities of goods distribution and logistics has emerged, generated by austerity measures, decrease in purchasing power (30-40%), the bankruptcy of some suppliers, traditional traders, distributors who compose marketing channels, suspending the activity of some intermediaries within logistic channels, such as carriages, forwarding firms, and so on.

2. Consumer behaviour under the impact of financial crisis and economic recession

The phenomena generated one after another as a result of crisis, appeared during 2009-2010 have as immediate effect the decrease in the purchasing power of the population, some research estimated over 30-40% [1], a drop in salaries and pensions, an increase in unemployment rate and inflation rate, a modification of fiscal legal provisions: VAT, excise tax, and so on.

Under these conditions, the purchasing behaviour experiences a new consumption behaviour as follows:

- Over 90% of the population reduces its purchasing power, especially pensioners;
- Over 30-50% of the population will reduce consumption to satisfy their basic needs, preferring cheap products, with discounts and own brands;
- They will no longer buy in large quantities, and will reduce the buying frequency, even when basic products are concerned;
- Given the tight budget per family, generated by the economic recession, the household budget will concern only the buying of products of prime necessity and sustenance. Very few families, around 7%, maintain their expenses budget for extra necessities;
- A significant and increasing weight will be represented by in-house consumption, especially with the rural population;
- Psychological changes related to buying decisions. Since the expenses budget of the population is continuously threatened by the

decrease in purchasing power, this will determine the buying decision to be taken before going shopping, whereas impulse buy will aim only at low or average value products;

- The major factor in the purchasing decision of the population is represented by price, promotions, free gift with each purchase, or attractive prices using packing, keeping the price, but offering larger packages.

Thus, the economic crisis will leave its mark upon the buying behaviour, which means that the buying decision will leave its psychological mark generated by the budget allotted to purchases, taking into account the changing times, the volatile income, without making an allowance on quality, health and certain consumption values.

3. Forms of influence on goods distribution and logistics under the impact of financial crisis and economic recession

- Taking into account the hard access to capital resources, a first restriction in the activity of goods distribution is the rigorous budgeting of making up the range of goods through selecting or carefully maintaining the suppliers (indigenous producers or importers), who introduce new products under well-known brands or deliver existing products with discounts, or presented as own brands.

- Another shortcoming is the lack of capacity to provide liquidity necessary for the acquisition of goods in bulk which keep sales over the breakeven point, and this led in many cases to the blocking of distributors' activity.

- Difficulty in making up the consumption lines due to the suppliers who changed the produced range of goods.

- The suppliers were subject to great fluctuations in meeting commercial terms and conditions, namely the unexpected change in prices, the reduction of payment terms, the request for payment instruments, guaranties, with a negative impact on the marketing channel in providing for the flow of goods and the making up of the consumption lines or the stock on hand able to ensure the breakeven point of the economic processes

and activities specific to distribution and logistics.

- The producers' effort concentrated less on product innovation and more on the avalanche of products with economic price both for well-known brands and the big retailers' own brands with a view to maintaining sales. Here we can appreciate the concept of packing, namely innovation in the packing of larger quantities, at the same price, with an impact on the economic price.

We encounter a reconfiguration of the logistic and marketing channels through the rapid expansion of modern supply chains, like hyper and supermarkets, in comparison with the traditional supply chain which will experience difficulties in having access to supply sources and goods purchasing from suppliers.

Even if during the 2009-2010 economic crisis the expansion of major hyper and supermarket chains was held at a constant level, the analysis of the period 2006-2010 showed that this expansion registered an increase in market share from 32% to 43% [2].

Figure 1. Modern trade kept its market share

Source: Revista Magazin Progresiv, ianuarie 2011, pag 60-61

Under the impact of economic crisis and aggressive policy to maintain the turnover of the big retailers, who will lay down more and more disadvantageous conditions on their suppliers, these will be forced to become more receptive towards the traditional, proximity marketing channels.

Under these conditions, suppliers will be supported by traditional traders to promote famous brands.

The biggest difficulty faced by the distributors, the wholesalers, in this period of economic recession, is to keep the balance between the sales and the returns from the customers, this being the main requirement for maintaining the financial stability of the participating firms within the marketing channel. The cash flow blockages on the market are numerous, with an impact on insolvency, especially in traditional trade.

Retailers reach full maturity since they look for cost optimization and the use of modern display technologies in their stores which could beat the competition and offer appropriate customer service.

In this period of recession, sales management at the level of middlemen will rely on prudence rather than expansion, both from the market opportunities perspective and the decrease in purchasing power.

The objectives set by middlemen as a result of improving the situation generated by the crisis are the maintaining of technical, organizational and operational capacity together with the development of logistic divisions.

Under the conditions of information technology and communication (IT&C), we shall encounter changes within the marketing channel, as well as the logistic one, so as to pass to a management of distribution chains based on an analysis of value and essential competences which could reduce the overall cost to a minimum and lead to an appropriate customer service.

The majority of promotion activities within the marketing channel aimed at shelf promotion since, during crisis, buying decision will depend on product availability which has a direct and rapid efficiency compared to the promotion of brand image with a long-term impact.

Moreover, merchandising firms continued to proliferate providing shelf arrangement and display with professionalism and respecting quality standards, through consultancy support and real time in-house service.

4. Conclusions

We notice a reduction of the economic activities and processes within the marketing and logistic channels.

The consumption behaviour, and especially the buying behaviour are under the impact of the customer's moderation decision. At the same time, we acknowledge the maturity of the participants concerning the distribution and logistic systems, in the sense of managing, optimizing, consolidating and maintaining the operational and financial capacities in order to succeed in overcoming recession and be able to use the opportunities

offered by the market. Therefore, both the consumers and the economic units return to the traditional values, becoming more prudent in managing sales, wisely controlling budgets, and to a rational behaviour.

A Multiple Regression Model for Country Risk Assessment for European Countries

Danciu Aniela-Raluca
Goschin Zizi

Academy of Economic Studies, Bucharest

anielaco@hotmail.com

zizigoschin@yahoo.com

Abstract

This paper proposes a multiple regression model for country risk assessment using the main economic-financial and political variables starting from the existing major risk rating systems. It is based on data provided by international organizations such as the International Monetary Fund, the World Bank, the Eurostat, etc. as well as by previous research papers of a large interest among the experts in this field. The model offers a complementary instrument for quickly, promptly assessing the country ratings based on the most relevant characteristics employed by prestigious agencies such as Standard and Poor's, Moody's, the Institutional Investor, etc. The model results are consistent with the ratings provided by these agencies, confirming its usefulness for country risk research.

Key words: *country risk ratings, economic risk, financial risk, political risk, non-recursive regression model*

J.E.L. classification: C51, G24

1. Introduction

As the economic and financial development of a country and the difficulties that it faces may have different origins, the concerns with finding appropriate definitions and measurements for country risk have been numerous. At present country risk is largely addressed as "the probability that a country will fail to generate enough foreign exchange in order to pay its obligation toward the foreign creditors" (Kosmidou et al., 2008, p.1). The existing literature on this topic acknowledges both financial/economic and

political components of country risk. According to the degree to which some of these components are emphasized, country risk is viewed either from the financial/economic perspective only, or from the combined financial/economic and political perspectives.

In response to the increased demand for the evaluation of creditworthiness, a lot of agencies such as Moody's, Standard & Poor, Fitch, the Institutional Investor, Euromoney, Dun & Bradstreet, etc. have developed expertise in estimating country risk. These estimates are presented in the form of ratings (or scores) and are generally viewed as indicative of possible future default.

The wide acceptance of several of the major rating systems indicates that, while they may not be perfect, they provide the currently best-known evaluation of country risk. It is therefore reasonable to base the design of any new rating system on one of the existing ones.

Starting from these overall considerations this paper proposes a new model of rating system based on a multiple regression model that captures the main characteristics involved in the assessment of risk.

The paper is organised as follows. Section 2 presents the model built-up for the country risk estimation, using economic and political independent variables. In Section 3 the variable selection is discussed considering three main criteria, namely significance, availability and uniformity of data across countries. Then, as a result of applying these criteria, the economic and political variables incorporated in the model are systematically analyzed. Section 4 deals with the econometric results interpretation, emphasizing the model robustness tests and

the most statistically significant independent variables. In Section 5 the consistency with the main agencies' ratings is investigated, proving very high correlation levels not only with Standard & Poor's but also with Moody's, The Institutional Investor, etc.

2. The model

This paper is aiming at identifying the main factors essential for country risk evaluations in order to build a country risk rating system based on a new multiple regression model, able to provide results which are consistent with the assessments of the prestigious agencies, while requiring less time and effort. To achieve this goal, we derive a non-recursive model of Standard & Poor's ratings, specified by the following regression equation:

$$Y = \alpha + \sum_{i=1}^9 \beta_i X_i + \beta P + u \quad (1)$$

where the dependent variable Y is the country risk rating given by Standard & Poor at the end of December 2008 (or, more precisely, a numerical representation of Standard & Poor's ratings), the independent variables X_i are economic variables and P is political variable (see section 3) and u is the error term. In view of the desired non-recursive nature of the model, the independent variables do not include directly or indirectly ratings of previous years.

Twenty three European countries were considered in our model: Austria, Belgium, Bulgaria, Czech Republic, Denmark, Estonia, France, Germany, Greece, Hungary, Italy, Latvia, Lithuania, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, United Kingdom, Croatia, Serbia.

3. Variable Selection

The selection of the variables involved in country risk assessment is often subject of criticism due to the subjectivity and arbitrariness involved in this process (Bilson et al., 2001). The selection of variables for our model was based on three main criteria.

The first criterion - *the significance of the variables* - is essential for achieving an accurate estimate of a country's

creditworthiness. As a consequence, an extensive literature review was conducted prior to defining the set of candidate variables for inclusion in our model.

The second criterion - *the availability of complete and reliable statistics* - is important in order to avoid difficulties related to missing data that could reduce the statistical significance and the scope of our analysis.

The third criterion - *the uniformity of data across countries* - ensures comparability. For instance, we avoided the use of the unemployment rate statistics disclosed by the World Bank because the underlying data are analyzed and compiled according to definitions which differ from country to country.

Based on these criteria of relevance, availability and uniformity, the following *ten economic/financial variables* were incorporated in the model: gross domestic product per capita, inflation rate, trade balance, international reserves, fiscal balance, exports growth rate, debt to GDP, financial depth, and exchange rate, unemployment rate, alongside *one political variable* - corruption level. These variables were deemed to be relevant for our research owing to their capacity to shed light on different issues related to the assessment of the country risk.

Dependent variable

- **Standard & Poor country risk ratings (foreign currency sovereign ratings.)** - The risk of default is generally defined by Standard & Poor as the probability that a sovereign obligor fails to meet a principal or interest payment on the due date and in full. Standard & Poor's ratings are based on the information provided by the debtors themselves and by other sources considered reliable.

Independent variables

- **Gross domestic product per capita** - The sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products. The Gross domestic product per capita was selected as a measure of the relative wealth of a country and its level of development.

- **Inflation rate** - The change in the national price level between two periods. The inflation rate used in our study is based on the consumer price index and is the annual

percentage change in the cost to the average consumer of acquiring a fixed basket of goods and service. High inflation rates indicate structural problems in the country's finances and may lead to sovereign economic crises, as governments hike interest rates sharply in order to strengthen their countries' currencies. Should a country be unable or unwilling to pay the current budgetary expenses, it must resort to inflationary money financing. High inflation rate results in a substantial consumers' purchasing power reduction and increases political discontent.

-Trade balance- The balance of trade in goods expressed as a percentage of *GDP* (purchasing power parity-PPP). This is the difference in value between a country's total imports and exports (including information of oil and non oil exports, consumer goods, capital goods) measured in current U.S. dollars divided by the value of *GDP*. Considering the trade deficit as a main cause of current account balance deterioration, this indicator reveal higher risks for the sustainability of international financial position.

- Unemployment rate- The percentage of the total labor force that is unemployed but actively seeking employment and willing to work.

- Exports' growth rate- Annual growth rate of exports of goods and services based on constant local currency. Exports of goods and services represent the value of all goods and other market services provided to the rest of the world. They include the value of merchandise, freight, insurance, transport, travel, royalties, license fees, and other services, such as communication, construction, financial, information, business, personal, and government services. They exclude labor and property income as well as transfer payments. Countries having a high export growth rate are expected to be more creditworthy. Indeed, exports are the primary source of foreign currency inflows and therefore have a significant influence on the capacity of the country to finance imports and service debt obligations.

- International reserves- This variable refers to gross international reserves, expressed in terms of the number of months for which the existing reserves can cover the cost of imports of goods and services. It gives an indication of the short-term capacity

of an economy to meet its imports obligations. International reserves give an indication of the short-term capacity of an economy to meet its imports obligations. The higher the value of RES, the lower the risk of default and the higher the creditworthiness.

- Fiscal balance- Fiscal balance is approximated by the ratio of central government financial balance (surplus or deficit) to *GDP*. The central government's balance represents the yearly fiscal balance. Fiscal balance and debt stocks of governments are crucial indicators when analyzing sovereign risk. The ability of governments to extract revenues from taxpayers and users of services is a key factor that helps to determine whether governments will be able to make full and timely payments of interest and principal on outstanding debt.

- Debt to GDP- It refers to the general government debt. The general government debt as defined by the IMF (2001) includes the consolidated budgets of the central, state/regional, and local governments, along with the social security system and other extra-budgetary funds engaged in noncommercial activities. Excluded are lending and refinancing and the assets/liabilities of commercial state-owned or guaranteed enterprises, except for any net financial transfers made as subsidies to these enterprises. This balance, i.e., the difference between total revenues and total expenditures, determines the net borrowing requirement of general government, which can be met only by running down financial assets or borrowing net new resources from the public and, thereby, adding to debt. Debt to GDP gives an idea of the ability of a country to make future payments on its debt. If a country were unable to pay its debt, it would default, which could cause a panic in the domestic and international markets. The higher the debt-to-GDP ratio, the less likely the country will pay its debt back, and the higher its risk of default.

- Exchange rate- It is defined as the ratio of the current value of the exchange rate to the moving average of the real effective exchange rate over five years (2004 to 2008). Exchange rate indicates the dynamics of changes in the exchange rate, by specifying whether the trend is up (>1) or down (<1).

- Financial depth- It is represented by the ratio of the domestic credit provided by

the banking sector. Financial depth is used to measure the growth of the banking system since it reflects the extent to which savings are financial. Households accumulate claims on financial institutions that, acting as intermediaries, pass funds to final users. Correlated to the development of the economy, the indirect lending by savers to investors becomes more efficient and gradually increases assets relative to the GDP. Viewed from this perspective, the ratio of domestic credit to the GDP reflects the financial depth of the country's financial system.

- **Corruption**- It is a good indicator of the "respect of citizens and institutions for the rules which govern their interactions" (Alexe et al., 2003, p.11). It includes business, political and police corruption.

The statistical data on the economic and financial variables considered in this paper come from the International Monetary Fund (World Economic Outlook database), from the World Bank (World Development Indicators database) and Eurostat while those about the ratio of debt to gross domestic product come from Moody's publications and unemployment rate from Central Intelligence Agency and Eurostat. Values of political variable are provided by Kaufmann et al. in two papers that are joint products of the Macroeconomics and Growth, Development Research Group and Governance, Regulation and Finance Institutes which are affiliated with the World Bank. All values refer to the end of 2008. The Standard & Poor country risk ratings were used for the twenty three countries considered in our model (at the end of December of 2008) and the results were very good.

4. Econometric results

We run the regression specified in the equation (1). The parameters of the regression model were estimated using Ordinary Least Squares (OLS) and the results are shown in Tables 1 and 2. The econometric results given in this section have been obtained using the SPSS statistical package and Excel.

The model exhibits an excellent fit, with the coefficient of multiple determination *Rsquare* being 92,28%, and the adjusted *R-square* 84.5%. Table 1 below details how the regression equation accounts for the variability in the response variable, while the Table 2 is giving the estimated coefficients (standard errors in brackets) and it also indicates whether the corresponding independent variable is statistically significant (at the confidence level of *1-p*).

Table 1 : Analysis of variance

	Sum of Squares	Degrees of freedom	Mean Square	F-stat
Regression	1342,14	11	122,10	11,94
Residual	112,204	11	10,22	
Total	1454,40	22		

Predictors: (Constant), *Financial dept*, *International reserves* *Inflation rate*, *Trade balance*, *Exports' growth rate*, *Gross domestic product per capita*, *Exchange rate*, *Fiscal balance*, *Debt to GDP*, *Corruption*, *Unemployment rate*

Dependent Variable: S&P RATING

Table 2: Regression results

Variable	Coefficient (Standard error)
Constant	7,153
Financial depth	0,015 (0,002)*
International reserves	0,113 (0,048)**
Inflation rate	-0,021 (0,029)
Trade balance	-0,009 (0,015)
Exports' growth rate	-0,011 (0,027)
Gross domestic product per capita	0,00037 (0,00018)***
Exchange rate	-0,031 (0,004)*
Fiscal balance	0,113 (0,051)**
Debt to GDP	-1,763 (0,483)*
Unemployment rate	0,062 (0,034)****
Corruption	-0,554 (0,121)*

*Significant at 99% confidence level ** Significant at 95%*** Significant at 90%

The regression results described above indicate that the proposed regression model has an excellent fit with the data.

Table 2 presents the regression coefficients. Eight independent variables are highly statistically significant (financial depth, international reserves, gross domestic product per capita, exchange rate, fiscal balance, debt to GDP), while unemployment rate is less significant (at 85% confidence level).

5. Consistency with the ratings of the agencies

In addition to analyzing the correlation level between Standard & Poor's ratings and those of the proposed regression model, the latter has to be compared with the ratings of other agencies, e.g. Moody's and The Institutional Investor. We present below the results of these comparisons, based on Moody's and The Institutional Investor ratings issued at the end of December 2008 and in March 2009 respectively. We shall start by presenting a brief description of the rating systems of Moody's and of The Institutional Investor.

Moody's sovereign ratings are defined, as "a measure of the ability and willingness of the country's central bank to make available foreign currency to service debt, including that of central government itself" (Moody's, 1995). Similarly to Standard & Poor, Moody's uses a nominal rating scale, which contains the same number of categories as Standard & Poor's ratings. A large proportion of countries receive the same rating from Moody's and Standard & Poor, and when they are different, the difference is usually not more than one notch.

The Institutional Investor country risk ratings were first compiled in 1979, and are published now regularly, in March and September of every year, for an increasing number of countries, which reached 145 in 2008. The Institutional Investor ratings are numerical, ranging from 0 to 100, with 100 corresponding to the lowest chance of default. The Institutional Investor relies on evaluations of the creditworthiness of the countries to be rated, provided by economists and international banks, each respondent using their own criteria. Responses are aggregated by The Institutional Investor,

greater weights being given to responses from institutions with higher worldwide exposure.

The correlation levels between the ratings given by the non-recursive multiple regression model and those given by Standard and Poor, Moody's and The Institutional Investor are reported in Table 3.

Table 3: Correlation between the non-recursive model and other ratings

	Our model	S&P	Moody's	The Institut. Investor
Our model	100%	94,53%	93,24%	89,52%
S&P		100%	96,24%	93,83%
Moody's			100%	96,31%
The Institut. Investor				100%

It can be seen that the very high correlation levels between the ratings given by the non recursive regression model and those given by Moody and The Institutional Investor underline the relevance of the proposed model.

6. Conclusion

This paper has attempted to examine, by means of a new non-recursive model, the relevance of selected common economic-financial and political variables and indicators employed by prestigious agencies for assessing the country ratings. We found that the most important variables in terms of statistical significance refer to financial depth, gross domestic product per capita, exchange rate, fiscal balance, debt to GDP and international reserves. The econometric results of our application demonstrate that the proposed regression model has an excellent fit with the data employed, supporting its usefulness for various research studies dedicated to country risk analysis.

We have not found any significant differences by comparing the ratings produced by our model with the S&P ratings.

Abstract

The Romanian banking system has made a significant progress over the transition to a market economy. This can be explained by the fact that the Romanian banks embraced banking strategies which had as purpose a performance improvement. In spite of this fact, they still have to cross a long way in order to catch up with the EU banking in terms of development and performance. This paper consists of a synthetic presentation of the main stages of evolution in the Romanian banking system from 1990 until now.

Key words: banking system, stages of evolution, the Romanian National Bank.

J.E.L. classification: G21

1. Introducere

The road covered by the Romanian banking system is one dominated by deep European reforms. The Romanian banking system reform started in the late 90's when the transition from a one-bank system to a composed one took place. Hence, this new system structured in two levels consisted in the Romanian National Bank and four specialized banks (Romanian Bank for Foreign Trade, the Bank for Agriculture and Food Industry, the Investment Bank and the Home Savings Bank). A plateau was occupied by the Central Bank, which became the sole organ of the issue. The Central Bank became responsible by law for the establishment and management of the monetary and credit policies, the licensing,

regulation and supervision of banking companies.

The second tier was entrusted to commercial banks, established as joint stock companies with the right to carry a wide range of operations, with the condition of fulfilling the requirements set by the Central Bank in terms of regulation and supervision. There are 3 stages to distinguish within the banking reform:

First of all, it's the period from 1990 until 1997, when the foundations of the two levels system were laid in accordance with the specificity of the market economy characteristics. At that time, three important laws were issued: the Banking Act, the Act on the Central Bank's status and towards the end, the law on privatization of banks in which the State is a shareholder. In the second stage, after 1997, the Central Bank acted to improve its banking laws in harmony with the European standards. Also, it initiated a process of improving and strengthening the banking system. This was an essential process needed indeed after the serious problems which existed during 1998-1999, when economic recession hit the banking system's weak links. The third step can be assimilated to the European Union integration and it reveals the impact this accession had on the banking sector.

2. Stages of development of the banking system in Romania

Until 1997, in terms of the structure of assets, the banking system has been characterized by a pronounced focus on the

four main state banks - Agricultural Bank, the Romanian Commercial Bank (BCR), the Romanian Bank for Foreign Trade (Bancorex) and the Romanian Bank for Development (BRD). This has been a tendency to blur, however, due to the emergence of new private banks. Thus, as a percentage of total assets at a system level, the balance of the four banks decreased from 83 percent in 1991 to 62 percent in 1998.

Another feature of the banking system during 1990-1997 has been to maintain a high degree of segmentation - reflected by a priority guidance of the state banks to finance the public sector, of the ones with Romanian private equity to finance domestic private economic agents while foreign banks worked mainly with large foreign companies which were present in our country.

The reform moved on and the transformations were consistent. In order to ensure a healthy economic base of the banking system and its functioning on a competitive basis, the Central Bank adopted a policy of cautious approval, which was a favorable setting to a relatively small number of banks. Even though these banks weren't many, they were strong, with solid capital. The general enthusiasm towards establishing new banks should be taken into consideration when assessing accurately the position of the National Bank of Romania in the issue (a phenomenon recorded in other post-communist countries), and on the other hand, the insufficient knowledge of the risks of the banking industry within Romanian societies.

All this time, an ongoing concern of the National Bank of Romania was to increase the efficiency of supervision in credit institutions and to primarily orient towards performance measurement and analysis of the dynamics of the situation of each bank. At the same time, we aimed to verify the compliance of the prudential indicators set out in regulations and of the measures to prevent the impairment of the financial situation of the banks concerned as well as the establishment of legal sanctions applicable when not respecting the rules.

In the 90's, the experience has shown that, apart from the existence of an adequate framework for prudential regulation and supervision, the health of the banking system requires mainly the proper functioning of the economy in general. Structural failures,

recorded in the real sector of the economy - especially the high degree of indebtedness to state of a large number of enterprises and service providers and the decline of the 1997-1999 period were reflected in the quality impairment of the banks' loan portfolio, especially of those banks of large exposure. The cases of the Agricultural Bank, the Bancorex Bank and the Column Bank became notorious-like. This trend was reinforced by the legislative framework, favorable to the debtor. Of course, it was about sanctioning inefficiently the non-payers and about cumbersome procedures for recovering the money by law enforcement. Another negative aspect was the absence of a liquid market which made not possible the capitalization of the guarantees on loans. The modest results regarding the restructuring of the real sector, together with the instability of the consumption price, of the interest rates and of the exchange rates have affected the behavior of commercial banks. Their appetite for lending to the real economy was low, but it increased the share of income from investments in government securities and foreign exchange. There were still strides to be done before we shall see the retail banking developing, in Romania.

Between 1990 and 1997, a prominent feature of the functioning of commercial banks has been the interference of the political factor, by means of special laws or decisions of government, under which were granted preferential loans to support energy and agricultural sectors. In this way, the rational allocation of resources for financing the economy has been distorted, a phenomenon that peaked in 1995 and 1996.

The solution to protect banks from such influences and to ensure sound corporate governance was provided by privatization. Although through the stand-by agreement for the period 1994-1995, the Romanian authorities have already pledged to the IMF to privatize the two companies with majority state-owned bank within a year, concrete results have only appeared a few years later. The stagnation of the privatization process had as reason the interests previously mentioned. Since 1997, when this economic orientation was given up, the economic policy has led to substantial changes in the banking system.

The preferential credit, accumulated especially in Bancorex and the Agricultural Bank, was considered a bad loan. It was time for banks to no longer be regarded only as a source of money, but to become effective instruments of the economy. Management teams and shareholders (either private or public) that showed unsafe behavior, practicing risky lending policies and showing negligence in the management of the banks, were faced with a hardship in November, which they were not used to. Such a conduct has had serious repercussions on several commercial banks from 1996 until the 1998-1999 banking crisis when the situation culminated.

The Central Bank's position was nuanced. As a general rule, the Central Bank sought to avoid crisis and the system used for this purpose, the whole arsenal of means provided by the banking law, including exercising the role of lender of last resort, obviously, with the risks in terms of moral hazard and the difficulty in terms of controlling the budget deficit. However, funding problematic banks in order to avoid systemic crisis was conceived such as to affect as little as possible the monetary policy, which was focused on ensuring macroeconomic stability.

While preventing the contagion phenomenon at a system level, the price of this balance policy between two contrary objectives consisted in the disappearance of some. In the second stage, after 1997 the Central Bank acted to improve banking legislation and to align to the European standards. At this stage, the deed directions were influenced by two major moments: the banking crisis during the years 1998-1999 and the invitation of Romania in Helsinki (December 1999) to start EU accession negotiations. It initiated a process of strengthening and improving the banking system. This was absolutely necessary because of serious problems in the years 1998-1999, when economic recession hit the weak links in the banking system seriously. The main threat to the viability of a banking system was, at the time of 1998, the failure of large banks, the state capital (Bancorex and Agricultural Bank).

In 1999, the National Agency for Bank Asset Recovery (AVAB) was founded and it took over the bad loans from these banks and

off-balance sheet assets from the same category in order to successfully carry out the restructuring process. The improvement procedures on the banking system led finally to the elimination of nonviable entities, getting in time to a correct assumption of the function of intermediate. Since the restructuring of the banking system outran the restructuring of the real economy, banks, in a first stage (2000 - 2002) have adopted a reserved attitude towards lending to the economy which has drawn complaints from the authorities and the public. The Central Bank intervened in this situation trying to explain that the prudential attitude they have shown is due to the large volume of bad loans accumulated by 1998. Subsequently, the lending activity has evolved both qualitatively and quantitatively. The restructuring activity, which has as purpose to clean up the banking system, was based on the banking supervision function and it was conducted from various points of view: legal, regulatory, organizational and from the point of view of the efficiency in checking and sanctioning banks.

However banks have remained the most important financial intermediaries. In the late 2000, the Romanian banking system holds more than 90% of total assets of domestic financial system. In addition, the opening of the European Union required the intensification of regulatory harmonization with EU directives and the principles of the Basel Committee, so that currently the domestic banking legislation is aligned with European standards.

After BRD, Bancpost, the Agricultural Bank and the Commercial Bank of Romania have been successfully privatized by the taking over of the majority shareholding by foreign financial institutions of enhanced reputation. Hence, foreign capital became dominant in the Romanian banking market.

Romania thus falls under the globalization trend although, in this case, "regionalization" would be a more correct term to use because the foreign capital currently in the Romanian banking market comes from European Union's countries. From this perspective we can say that we are more integrated than other countries such as Sweden, Ireland, where more than 50% of the banking system is national property. In future, it is possible

for strong Romanian banks to show up and to act as key players in the system.

European financial market trends begin to make their presence felt on the national banking market. Thus, European banks' tendency to become larger has been observed even in Romania where they developed a process of concentration through mergers and acquisitions. An example is the merger between HVB Tiriac Bank and UniCredit Romania Bank and deploying new business entity under the name UniCredit Tiriac Bank. Simultaneously, there is a specialization trend very well illustrated in SME financing by ProCredit Bank, the housing banks created by Raiffeisen Bank and UniCredit Tiriac Bank, and in credit for cars created by Porsche Bank.

Also, it is very important the fact that once with the accession to the EU and the market liberalization, a number of 207 foreign institutions have notified their intention to provide and conduct banking business in Romania. The percentage of assets held by banks with majority private capital in the Romanian banking system in the total assets at the end of 2009, 92.7%, while banks with majority state owned or held a share of only 7.3%.

After the accession to the EU, the link with modern banking practices provided by the banks with foreign capital together with the increasing customer requirement led to rapid uptake and development of services involving advanced technology.

Composition of the banking sector ownership in early 2009 was as follows:

Table 1. The structure of the banking system ownership

	2008	2009
Banks, Romanian legal persons	32	31
<u>Banks_with_majority state-owned or fully state-owned which of:</u>	2	2
With a majority state-owned capital	1	1
With a fully state-owned capital	1	1
<u>Banks with privately owned capital, which of:</u>	30	29
With a majority domestic one	3	4

With a majority foreign owned one	27	25
<u>Foreign bank branches</u>	10	10
<u>Total number of banks and foreign bank branches</u>	42	41
<u>CREDITCOOP</u>	1	1
<u>Total number of credit institutions:</u>	43	42

Source: The National Bank of Romania

Due to technical progresses, Romania has been able to overcome relatively quickly the period of checks and paper-based instruments and to subscribe to the phase of the electronically processed tools, phase that took decades to other countries. Thus, in addition to the accelerated growth in the number of users and volume of transactions conducted by electronic means of payment in a few years, became the exception rule in Romania gaining more ground in the internet banking being in accordance with the development trends in the European Union and even global e-banking services and e-finance. However, the widespread appeal of information technology allowed the introduction of a new concept in Romania – self banking - which on one hand, satisfies customer demands for banks to have flexible working hours and on the other hand, enables them to reduce the operational costs, this being a very important element in the context of fierce competition.

An expression of the increasingly important role played by information technology in the development and modernization of banking services is the Electronic Payment System (EPS) - although with some delay - to reduce settlement time, reduce costs, fees, interconnectivity with the European system TARGET And increases system security.

The influence of the process of regionalization is the trend of innovation shown by local banks, reflected in the continued diversification of product range offered to customers, either by opening branches with a distinct profile (insurance, brokerage, leasing), or by providing new products (credit property, credit for vacations, etc...). In some areas (ex. leasing), commercial banks took advantage of the relatively weak regulation and supervision, in order to maximize profits in a mature market failure. As regulatory authorities take

measures and surveillance will remain fewer "loopholes" for the extraction of rents (rent-seeking).

The global economic and financial crisis, manifested intensively in 2009 represented the main negative context in which both the real and the financial sectors operated, in Romania. Due to stable levels of liquidity and solvency indicator, the banking sector has absorbed these shocks better, but the financial performance was much reduced and the risk of growth of bad loans was emphasized. In the short term, the perspectives of the banking sector and of the financial banking system generally depend largely on restoring the confidence, the success of sustainable economic recovery and international developments.

3. Discussions

Looking ahead, the development of the Romanian banking system has some predictable ways and others in which developments may be less reliable. In the category of predictable falls the significant reduction of the bank intermediation costs. First of all, I refer to the reduction of the cost for transfer payments, once with the introduction of the Electronic Payment System (EPS) in order to get an approach of these costs to the level of costs in the European Union. As far as the cost of the large payments is concerned, it will cut several times per unit of payment. Another area where in the period ahead, the reduction of intermediation costs will be highlighted is that of household deposits. The contribution of commercial banks for the establishment and operation of the guarantee fund then deposits in the banking system was substantial. The Fund has created a great asset, allowing the lifting of the guarantee limits on the European level of coverage. And I think it would be time to think about reducing the contribution of commercial banks. Another measure is related to minimal obligatory reserves in lei. Fighting inflation had to be taken with various instruments, which the National Bank of Romania has used the most, but high costs were unavoidable, for financial intermediation in general and local currency lending in particular.

The reduction of reserve requirements is a process that has already been initiated, it will continue in the next period and it will result in both cost savings and commercial banks to avoid a dangerous mismatch between main savings in lei and the majority credit still in currency.

Another trend that is obvious and it will continue for a considerable time, along with the development of the Romanian economy, of the increase of competition in the banking sector, the emergence of new banking products and further remonetization of the economy and the extent of disinflation is the non-government credit share in GDP growth.

Also, another definite issue is the narrowing of interest margins under the pressure of the competition in banking system. It makes sense to be so, because on efficient markets the profit function is obtained from volume rather than from margins. It is obvious that neither can Romania avoid this process. The winners will be those who will understand earlier the logic of the competitive markets, which applies everywhere in the world.

Within the category of evolutions less certain is the number of banks that will be operating in Romania during 2012-2015. There are contradictory views regarding this issue. On one hand, they say the number of banks will be reduce and this is supported by the argument that, at the moment, half of the existing banks in Romania, have less than 10 percent of assets. It is obvious that something needs to happen here. They will either increase their market share or merge or be acquired.

It is less certain that this will reduce the number of banks, as it happened in 2004, there may be new categories of banks (banks specialized in house acquisitions, car purchases). On the other hand, those who believe that banks will not decrease the number come with the argument that the degree of financial intermediation (number of inhabitants per one unit banking) is still small. For example, in Switzerland, there is a bank to 1500 people. This argument is not sufficient because the number of banks may fall, but their territorial network (branches, agencies) can expand strongly.

As for the number of banks in Romania, during 2012-2014 (when the euro will be adopted), this will be the result of complex

processes in which, not least, the competition among banks as well as the major policy market players will play an important role on the development of regional networks and their credit profile. In the future, quality of service offered by the Romanian banking system will be more important than the number of banks. The global economic and financial crisis, manifested intensively in 2009 represented the dominant negative context in which the real and financial sectors operated in Romania. Due to stable levels of liquidity and solvency indicators of banking sector has absorbed these shocks better financial performance, however, were much reduced and the risk of growth of bad loans is emphasized. In the short term, prospects for the banking sector and the national financial system-generally depend largely on restoring confidence, the success of sustainable economic recovery and international developments.

4. Conclusions

The above being given, we can define the main objectives of the banking system in Romania as following:

- providing financial intermediation based on a modern and robust banking system structured effectively supervised, properly regulated so as to dispose of local imbalances and to ensure macroeconomic stability;

- to assess and to monitor the financial stability in order to enhance the capacity of efficient allocation of resources, to absorb potential shocks, preventing adverse effects of shocks on the real economy;

- to increase the administrative capacity of the central bank in ensuring the stability of the financial system in order to support its primary objective of ensuring price stability;

- to strengthen the quality of the surveillance process: adaptation of the National Bank's regulations to the specific risk profile of each credit institution, greater emphasis on the role that institutions play in managing banking risk management;

- enhanced surveillance will be based on prudential indicators calculated on a consolidated basis: credit institutions, Romanian legal person, is supervised by the Central Bank if it has subsidiaries or participations in credit institutions and / or financial institutions in Romania or abroad. The credit institution, being a Romanian legal person, is supervised by a competent authority in another EU member state, whether it's a credit institution subsidiary in that country;

- the promotion of attractive investment vehicles for institutional investors (especially pension funds, mutual funds and insurance institutions).

- to create conditions for an efficient banking management regarding long-term investments.

The Global Economic Crisis... Is This the Beginning of a Large Recession?

Abstract

This paper analyzes the impact that the global crisis has on the labour market both in Romania and in Europe. The financial crisis is felt in Europe in most of the economic sectors (automotive, chemicals, transport, Real Estate) and everything suggests that the negative effects will extend to other areas. Romanian industry's crisis plan was backed by the global financial crisis. The measures which will be taken by the affected countries are very important in terms of restoring a balance in the future labor market.

Key words: the global crisis, the labour market, the average monthly earnings, the employee.

J.E.L. classification: G01

1. Introduction

The crises can be defined as a situation characterized by pronounced instability. Furthermore, it's accompanied by volatility and an increasing uncertainty. In crisis situations, people are in a constant state of anxiety and uncertainty about the future, displaying fear and even panic. The self-preservation instinct urges them to behave irrationally and sometimes this is emphasized even more obvious because of the fact that each of them has a cognitive ability and an information filter. Hence, they understand the phenomenon in their own way and then they translate it into a conduct related to a particular market. (Pop, 2002).

The problem found at defining the crises is the incapability to determine the degree of volatility or the one of market-driven destabilisation so that such a phenomenon

fits a crisis category. How high should the inflation, unemployment or the fall in GDP of a country be, in order to establish its entry into a crisis? The recession is established conventionally at two successive quarters when dealing with the GDP decrease of a country or region. National Bureau of Economic Research (NBER) defines crisis as a significant decline for several months in the economic activity and it's reflected in a lower GDP, a lower individual income, the reduction at the levels of employment and a reduced industrial production and consumption .

Unfortunately a crisis occurs only when its effects influence a large number of people /companies, even though shortages may exist in a latent and not so visible, slowly damaging our existence. Crises are not hard to predict (their causes are quite clear), but one that will make such a prediction would be hard to be believed in by most of us much too little concerned about global warming or monetary expansion and mostly concerned about a way to better capitalize our position as privileged. (Bacescu & Fota, 2009)

2. The current crisis vs. great recession

In the 30's, the German social expenses were decreased by the great concern which the state had on inflation and its determination in driving fiercely a deflationary policy with the purpose of supporting the brand. In 1931, Employer's Association required employers to reduce wages and social charges. Unions claimed an increase in the unemployment benefit. The unemployment insurance seemed responsible for its dissolution, although it was designed to support social coherence. The increase in the number of

unemployed made funding not possible, but the system was partially rescued by government intervention, although this turned out into a decrease in expenditures. An important part of German world moved to a different path than the one expected by Weimar and it joined the Communist Party. (Miron, 2002)

As in Germany, the crisis of 1929 tested the English help system of the unemployed. Observers say that while this system was a handicap for a recovery nevertheless was it a privilege to the unemployed. Even in 1931, sharp reductions in income affected the aid for the unemployed as well as the social sector. In 1935, a Means test was introduced for those who had the right to control resources. In this period, the English social policy didn't come across great changes apart from a few steps over housing (Greenwood Act) and pensions. In France, the social protection policy persisted between the two world wars which were of high priority for the French. In 1939, the Family Code was passed having the effect of strengthening the aid to families with more than three children. (Revue politique d'Economics, 1998)

The economic crisis which states are going through in today's economy resembles increasingly the Great Depression of the '30s. It's the first time after many years, when the world economy is facing recession. Maybe it's the first time after many years when we deal with a crisis located in developed countries, not only in developing countries, but one spread worldwide.

As during the Great Depression of the '30s, world trade collapsed, capital evaporated, and the banking system no longer worked. Deflation is an increasing threat in the conditions under which companies reduce production, wages and prices. Leaders from around the world are struggling to halt the decline. It is a situation similar to that of 1929-1930. The current downturn could leave a lasting imprint on the economy and society, just as happened during the Great Depression. Following the crisis of the '30s, Americans have abandoned shares while their resources were overstretched and they have sought government support. Now, another generation would be able to draw similar lessons from the dramatic collapse of their lives. This will leave a trace on the collective psyche, and people will become

more conservative in lending activities, credit and investments.)

Mark Zandi, chief economist at Moody's Economy.com, says that in the '30s, the unemployment rate rose to 25% and the economy contracted by more than a quarter. No economist predicted a return to extreme harsh conditions in those years, but today's economy contracted at an annual rate of 6.2%. In the last quarter of 2009, it decreased by 7% in the first months of 2010. The unemployment rate climbed to 8.1% in February, a maximum of 25 years. Some industries are already in severe recession. The auto industry sales declined by 55% from the peak reached in July 2005. The production of cars and trucks fell in January 2009 at an annual rate of 3.9 million, the lowest level since 1967 and 67% below January 2005. Financial services industry is also seriously affected. Since the crisis started in mid-2007, institutions around the world have accumulated losses of 1.200 billion dollars. Announced layoffs have exceeded 280,000. (Bacescu & Fota, 2009)

Mark Gertler, professor at New York University, states that there has been a significant disruption of the financial system, just like in the '30s, when more than 10,000 banks had collapsed. Overwhelmed by the losses, banks accumulate capital instead of resume lending. Only two or three times a century can such a blockage occur and it can generate a spiral in which the weakness in the economy and financial industry are fuelling each other being very difficult to beat. However, particularly worrying is the collapse of the labour market. Dow Jones Industrial Average fell by 54% from the peak reached in October 2007. On a similar period, 1929-1931, the index has lost 55%. It decreased by 89% since its peak in 1929 before starting to recover in mid 1932.)

The current economic downturn is global alike the one during the Great Depression. IMF says it will be the first time since the Second World War when the United States and other industrialized countries will suffer a simultaneous decline in savings. World trade registered a rapid decline while the credit crisis reduces funding for exporters and importers. The volume of trade in goods registered an annual decline of 22% in the fourth quarter 2009 (according to the CPB Netherlands Bureau for Economic Policy

Analysis), while the decline in the period 1929-1932 was 35%. Government's officials reacted more quickly than their counterparts did so during the Great Depression and they tried to find solutions to end the crisis. The problem is that the economy appears to fall faster than strategic effects are seen. Regardless of how the way it is defined, the further deterioration of the economy will probably leave lasting traces. Savings rate has already climbed 5% in January 2009, the highest in almost 14 years. (Bacescu & Fota, 2009).

3. The Crisis in Europe and Romania

European industry feels the effects of international financial crisis in most sectors (automotive, chemical, transportation, real estate) and everything seems to indicate that negative effects will extend to other areas. In late 2008 BASF, the chemical industry world leader has temporarily suspended work in 80 factories, a move that affected 20,000 employees, while the French group Rhodia has reduced production by 40% in three plants in France. European Chemical Industry Federation estimates a drop in production in the chemical industry, except pharmaceutical sector, up 1.3% in 2009. European steel producers could show the financial results decreased by 43% in 2009, according to U.S. investment bank JPMorgan estimates).

Since 1999, for the first time since its founding, the euro area economy has entered recession. The Organization for Economic Cooperation and Development (OECD) appreciates that no economic growth is expected before 2010, expecting instead an increase in unemployment. Also, reduction of credit contributed to lower construction in Europe, and any estimate of an improvement before 2010 would be hazardous, according to a study conducted by the world leader in credit insurance, Euler Hermes. After a general decrease in demand, the air transport companies registered in September 2008, the first decrease in international passenger traffic in the last five years and the most severe decrease in the transport of goods in the past seven years, according to an announcement of the International Association Airlift).

Romanian industry's crisis plan was backed by the global financial crisis. HR specialists agree that the economy's fall will have a direct impact on wages and job number. Companies are reluctant to fill vacancies. The unemployment rate was 8.3% in February 2010, according to the National Agency for Employment (NAE). At determining this figure, it was taken into consideration the return back home of Romanians abroad, which, however, prefer to live on the unemployment benefits received from abroad.).

According to the Trade Register in Romania, in 2009, approximately 140.000 companies have suspended work, this figure representing an increase of 1009.59% from 2008. Companies that opted for volunteer dissolution increased by 472% and volunteer removals increased by 173%. The closure of these companies has resulted in the unemployment of 56.000 people. A calculation showed that the state has lost about 100 million lei only by failures to receive taxes from wages.

The image number 1 illustrates a top ranking concerning the unemployment rates, in counties in Romania in October 2009. The highest unemployment rate was recorded in the County Mehedinti (13.2%) and lowest in Bucharest and Ilfov (2.1%). NEA Director said that the main areas affected by economic crisis and which are reflected on the employees are the constructions, durable goods field and the ones of current use.

Figure 1. Top ranking concerning the unemployment rates in Romanian counties

Source: own graphic representation taking into consideration: <http://www.wall-street.ro/articol/Economie/75141/Topul-judetelor-cu-cele-mai-mari-rate-ale-somajului>

From October 2009 until the present, unemployment rate has always been changing. For February 2010, there is the top 10 counties in Romania with the highest unemployment rate: Mehedinți County-14.6%, Vaslui County-14.2%, 13% Alba County and Teleorman County, Dolj County-12.9 %, Ialomita County -12.8%, Covasna County - 12.4%, Galati County - 12.3%, and Gorj County, Harghita County - 11.5%, Caras Severin County -11.1%, Hunedoara County and Salaj County - 10.9%.)

In Romania, the employment among workers with higher education increased at the expense of people with secondary education, whose employment fell by 3.4%. But there are some categories in which it is difficult to find jobs, as graduates or unemployed persons and it's about the areas of unstructured activity. If pre-crisis rate stood at 20% of young people, today there is a high level of long-term unemployment, which is about 50% of the unemployed.)

In 2008, since the growth, average real wages have decreased and have continued to decline in 2009 (evolution depicted in Image 2 and 3), the main reason being the increase in unemployment, which puts pressure on remuneration levels. Real wage decline is due partially to reduction of working time between 2007 and 2009.

Figure 2. Average monthly gross earnings and the total net earnings per economy in 2008 vs. 2009

Source: Press release INSSE of 4 January 2010

Figure 3. Average monthly total net earnings in 2008 vs. economy. 2009

Source: Press release INSSE of 4 January 2010

The main problem is the relationship between financial crisis and the real economy. It is still present and repeated in the influence on consumers and investors. As the international economic shocks in the financial sector have affected every sector, human resource departments are about to record a decrease in the next permanent recruitments and a significant increase in the recruitments of a temporary nature. To overcome such a period, a company must maximize the efficiency of work and labour costs are automatically reduced. Employers will think more carefully on their business plans, and employees will be more reserved about changing the workplace. Overall, analysts say that this crisis has a beneficial effect: we learn to make savings. (Bacescu & Fota, 2009)

Romania will record as well the consequences of the crisis. Some of the foreign investments have already frozen and it's mainly about Spanish real-estate developers who began to diminish the work in Romania. Some of them have closed yards and went home. Companies will be thinking twice before hiring and they will be revising their budgets. Employment began to decline in the EU and the euro area as a result of economic crisis. The number of employees has decreased, but the occupancy rate was smaller than the restricting economic activity. The working hours were reduced and as a consequence, the full-time employees work 0.7 less hours per week in the EU and 0.8

less hours per week in the euro area. Image number 4 shows this fact. Part-time EU work rose from 18.3% in the second quarter of 2008, to 18.8% in second quarter 2009 and from 19.6% to 20% in the euro area. 22 member states registered increases of this activity, while Romania was among the four countries that experienced decreases in part-time work from 0.1% to 10% in the total employment.

Figure 4: Performance of full-time work during 2007 - 2009

Source: own graphic representation

According to a Eurobarometer survey published by the EC, six out of ten Romanian people consider the economic crisis as the main challenge facing the currently developing countries. Poverty is the second major challenge in the opinion of 55% of the Romanian people, the third place is occupied by poor governance (18%), followed by the food crisis (17%). Across the EU, the situation is quite different. Poverty is the main problem (50%), while the crisis is in second place (35%), followed by the food crisis (27%). Europeans agree that the development is important (about 90% EU, Romania 82%). The survey is clearly showing that citizens expect their governments and the European Commission to strive in order to gather funds for development. The percentages are similar (61% European, Romanian 52%) even regarding the EU's positive contribution to debate on global development.

Although the living of Romanians working abroad changed as well as their earnings and the gains sent to country were halved, few have opted to return to the country. In addition, in 2009, 350,000 Romanian people gave up working abroad, most preferring to engage in agriculture, hotels, restaurants or medical field, according to the National Agency for Employment (NAE). The countries Romanian people preferred are: Germany, France or Denmark. Romanian drain will continue this year, mainly due to lack of job offers on the local market and job insecurity or low remuneration in comparison with the European employers offer, according to recruiters.

Romanians still cling to their jobs from outside for strictly financial reasons. In Spain, where, according to the National Institute of Statistics, almost 800,000 of our compatriots live, a laborer may get between 400 and 800 euros, while those with secondary education earn 800-1200 euro per month. For employees with higher education niche, foreigners offer salaries much higher than in Romania. For example, in Germany a specialist has 5000-6000 euros gross win, while a sales manager in Belgium reached 1,500 euros, and a site director receives 4,500 euro in France. In Romania, in the province, the salary of unskilled workers didn't go for 300 euros and 250 euros in 2008, after a year of crisis. Similarly, an employee with higher pay and a maximum of five years experience stops at the threshold of 500-600 euros on average.

4. Conclusions

Even though it's not the first time the world economy faces recession, however, it is the first time we deal with a crisis located in both developed and developing countries. The collapse of key market sectors, at the beginning, has left the "wounds" deep into the global economy but this was somehow recovered. Moreover, as it was expected, the "air bag" of countries with strong fiscal positions faced better the crisis than that of developing states. Developed countries could use their investment in infrastructure and social sector in order to combat deflation, while less developed states confronted much more difficulties and, furthermore, in their case, the crisis is far from being finished.

At the beginning, the crisis was about survival and getting enough cash to help pay staff and suppliers. Today, companies are restored financially, being more interested in re-evaluation of their business model and flexible operations. At the same time, bankruptcies are also obvious, expecting growth in 2011 compared to 2010. A return to what was before 2008 may take many years to come. Romania's exit from the economic crisis needs a favorable external context, internal stimuli, fiscal policy and maintaining the agreement with the International Monetary Fund according to the economists of the big banks in Romania (BNR, BRD, ING, BCR) during the Analysts Association Annual Conference Finance and Banking meeting, in Romania (AAFBR).

Staff Policies in Rail Transport

Dăneci-Pătrău Daniel
„Spiru Haret” University of Bucharest
danusidenima2@yahoo.com

Abstract

A staff policy well planned and well adjusted represents a way, by no means negligible, to contribute to the supporting of a competitive strategy of the organization. The employees, well selected, have a lever effect over the company's productivity, because they use their talent, experience and their skills for the profit's increase, occupying the given positions. The absence of some policies and methods and techniques of recruiting and selection determines the costs increases which are associated to them, and finally, the lowering of the general level of the company's competence.

The article makes obvious the principal tendencies of the staff's policies in the National Company "CFR" SA, after an analysis of the way in which the planning, recruiting and selection are made, with the view of staff employment with executive functions, but also management and administration, in the railway transport.

Key words: recruiting, selection, human resources, railway transport

J.E.L. classification: M12

1. Introduction

Especially, the railway management has as object the maintenance and the improvement of the existent railway system, to allow his continuously use, by the commercial exploitation of the traffic in an efficient and safe way. In addition, as stated Simuț Viorel in [4], the adequate management should take into consideration the problems regarding the productivity and the effectiveness of using the human resources. The railway management can be seen as a process which tries to optimize the general performance of the railway exploitation administration, of the railway system, for a long period of time.

The effects of the railway transport are important; it is an essential component of the economical and social development process, very often, spending a very big amount of the national budgets. It is a powerful correlation between the covered kilometers and PIB. This thing helps the development through the commerce facilitation, both national and international, improving the population access to the work's places, to education, health attention and other services. To realize the objectives established by the owner, the railway managers should use more efficiently the resources in their hands. These resources may be a source of power but also a power of compulsion.

The main resources which are at the manager disposal are: finances, the market, people, tools and equipments, rolling stock, different materials and infrastructures, the management process of the trains circulation, the auxiliary patrimony, telecommunications, information. In the railway companies, most of these resources represent the activity object of some specialized directions. Thus, the human resources direction deals with the recruiting processes, selection, employment, motivation, staff's evaluation, marketing direction – transport's market aspects, exploitation direction – trains' traffic management. The information is organized according to the coordination and decision levels. Generally, the manager should use the necessary resources for the structure's advantage that he manages, and implicitly the company's advantage. For example, the staff manager doesn't only control the human resources, but also helps them, gives them advices, supports the others managers to use them. Besides the production of a profit, like most of other occupations, the management determines characteristic satisfactions: the obstacles exceeding by solving some difficult problems, the creation of some visible changes in the real world, a diversified society, always changing, career and

consideration in different societies.

The railway infrastructure administration, public or private propriety of the state, is assured in Romania by the Railways National Company "CFR" SA. The Company CFR functions on the basis of economical administration and financial autonomy and benefits by allocation from the state budget, under activity agreement, for the Romanian railways public infrastructure and for the realization of the projects of national importance to assure the Romanian integration in the European railway transport system.

Realizing the activity object, CFR assures the execution of the public railway transports of passengers, baggage, wares and others goods, on the basis of the transport contract with a view to satisfy the public, social and defense interest. The public railway transport is organized and is effected on market commercial principles.

2. The assurance process with personnel

The staff recruiting represents the process of searching, localization, identification and attraction of the possible candidates, the capable candidates are selected, who present the necessary professionally characteristics or who correspond best to the demands of the vacant work places, actual or future in the company. The human resources recruiting is the managerial process of maintenance and development of the most adequate internal and external sources, necessary to assure the competitive staff to realize the organizational objectives.

The staff selection represents the activity of the human resources management which consists in selecting, according to some criteria, the most competitive or apt candidate to occupy a position in the company.

Any arisen modification in the company has as correspondent his organization. The bigger modification amplexness, the intense are its organizational implications. Even it is about the execution work places or

administration and management, the origin of a recruitment derives either from the necessity to create a new job, or from the disintegration of the effective because: resignation, transfer, moving, retirement, etc.

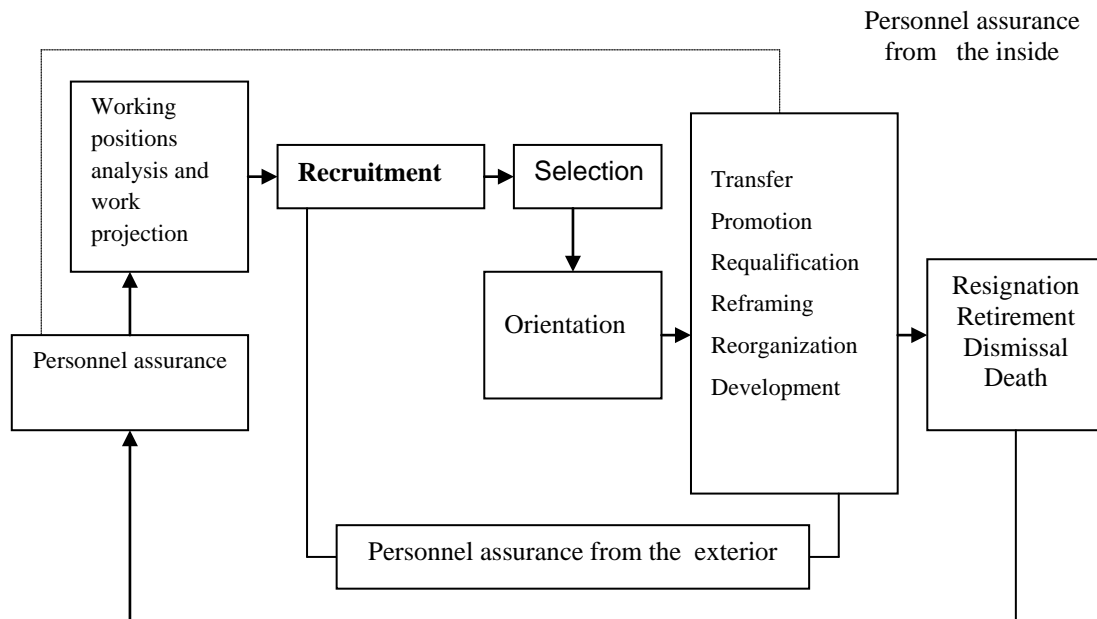

The first signal on the line of employment of some persons in the company, starts, generally, from the direct hierarchically chiefs of the compartments (station chief, circulation regulators chiefs, chiefs district lines, chiefs offices, divisions chiefs, etc). who have qualitative and quantitative difficulties to realize the tasks. These chiefs draw up a "statement form", where there are included a lot of the information necessary to describe the job and even to define the candidate's profile. Also, he has to make appreciations regarding the term and the period wherein the respectively statement appeared. With the hierarchical chiefs and company's management, such document should arrive at human resources compartment.

Before the launching of the recruiting operations, the statement opportunity is verified. The opportunity diagnostic is realized inside of the human resources compartment, which, through an interrogative logical model verifies when, other possible solutions and less expensive were taken into consideration, namely:

- if all the amelioration possibilities of the productivity were studied and applied;
- if they resorted to provisory solutions which can supply, a certain period of time, the demand of the setting up some new work places; it is the case of the work over program, of some employees on a determined period, staff transfer, production in collaboration, etc.

As mention D.J. Cherrington [1], the assurance process with staff from the inside or outside the organization can be seen as a succession of activities specific to the human resources domain, activities absolutely necessary to fulfill the individual and organizational objectives.

Figure 1 The assurance process with personnel

Sursa: Cherrington, D.J. *The Management of Human Resources*, Editura Prentice Hall, New York, 1995

The assurance process with personnel from the company exterior includes the recruiting, selection and orientation or the personnel integration, while the assurance with personnel from the company interior supposes some transfers, promotions, re qualifications, re framing, also the eventual retirements, resignations or deaths.

The recruitment connections with other activities of the human activity administration are intense. Thus, the recruiting takes into account the working positions analysis and the work projections, because the fundamental results of these activities, respectively the working positions descriptions and specifications are essential in the personnel recruitment process. This means, that the person who recruits has to have necessary information regarding the working position characteristics, and the qualities of its future holder.

The personnel recruitment follows logically the human resources planning, because it has like purpose the identification and attraction of the competitive candidates to complete the necessary net or the personnel supplementary needs. This means that the company's recruitment effort and the methods which should be used depend on the human resources planning process and on the

specific working positions demands which are to be occupied.

The knowledge in time of the personnel needed or its anticipation, as consequence of the human resources planning process and analysis and work projections, allows the development in good conditions and with more success chances of the personnel recruitment process.

The determination of the future necessary personnel is a complex process with two essential components:

- the foreknowledge of the personnel demand;
- the foreknowledge of the future personnel offer.

The future personnel demand on a given planning horizon can be estimated starting from the company's assembly strategic plans. The purpose is to specify the working positions (functions, jobs) necessary for the company's future and the working positions number necessary for each working position. The necessary information is taken form:

- Company's internal informational systems: planning systems of the railways transport capacities and analysis and projection systems of the working positions;

- External sources: railway operators associations, governmental statistics, specialized firms which offers access to the public data basis.

So, the gross personnel number is determined, representing the working positions number estimated on company's total and personnel categories.

The future personnel demand on the same horizon can be estimated starting from the current personnel availability (the persons number who has necessary knowledge and skills to occupy certain position), which is converted in the provided personnel availability on the planning horizon given by the tendencies' extra polarization already showed (retirements, resignations, promotions, transfers). Net personnel necessary is obtained for each working position as follows: Gross personnel necessary - the provided personnel availability.

Net personnel necessary can be: *positive* – and actions are required, as it follows:

- recruiting (the selection of the candidates group from the company's inside or exterior);
 - selection (the selection of the persons proper for each working position);
 - formation and professional integration;
- or *negative* - and actions are required, as it follows:
- personnel reduction by dismissal;
 - encouragement to retrial before the term, taking into consideration that at CFR there were active for a long time the work groups I, II and III;
 - encouragement of the voluntary departures.

The main objective of the personnel selection is to obtain those employees who are near the desired performance standards and who has more chances to realize the organizational and individual objectives. The personnel selection, according John M. Ivancevich and William F. Gleuck [2], is perceived as a series of phases wherewith the solicitants pass, each phase being are treated as an obstacles, which select systematically the candidates' number who advance in the next phase. Nevertheless, in practice all the selection process steps are not examined. There are situations when the candidate proves that he has the correspondent qualities

to occupy the working position, the selection steps number is reduces, the employment decision being taken after the first interview.

According to A. Manolescu [3], each organization should choose the personnel selection methods and instruments which correspond best to the exigencies of the offered position, which give equal chances to each candidate and doesn't contradict the intern cultural medium.

3. Hiring personnel with executive functions

The railroad personnel has an activity in railroad transport with particularities generated by a continuous work on and near moving vehicles, with frequent and long travels, in any type of weather and with a responsibility for train's safe traffic and for the integrity of the passengers and goods that imposes a strict disciplinary organization. The personnel employment to CN CF "CFR" SA is made by examination, exam and/or other selection forms, respecting the training and seniority conditions. By other selection forms we understand: interview, questionnaire-test, grille-test, skills-test, etc. Before the selection of the applicants, the recruitment process is initiated. The first stage of the recruitment is the action that takes place from the request for new jobs until the definition of the applicant's position and profile for those requirements that have been restrained.

Working standards are elaborated by CN CFR SA, in accordance with the syndicates, and are made known to the employees at least five days before they are applied. Elaborating the working standards is a continuous process, in accordance with the changes that occur in the organization and the level of the work's technical endowment. The re-examination of the working standards is imposed by situations in which they do not assure a complete grade of occupancy, they lead to an excessive stress or do not mach the conditions for which they have been elaborated. By re-examinations of the working standards the basic wage, negotiated according to the CWC, will not be decreased. The personnel standards, resulted after applying the working standards, the working instructions and the safe traffic regulations, according to the particular conditions of each

sub-unit. Hiring personnel with executive functions is made by contest or exam only for vacant positions established by standardising, personnel standards or function chart. The contest or exam are held in Romanian only from published bibliography and themes and is made of theoretical, practical and aptitude tests, from case to case. The exam for unqualified personnel consists, usually, of a practical test. The contest, the exam and/or other forms of selection will be held in front of a commission approved by the division that has the competency of employing. A syndicate representative will assist the exam or contest. The employment is made according to the exam grades. When two candidates obtain the same grade CN CFR SA employees family members (husband, wife, children) have priority in occupying the position. The results of the contest or exam are valid only for the vacant position that was held for. The limited period individual working contract cannot be signed for a period greater than 24 months.

In order to meet the need for university graduating personnel in positions with low employment expectations, the company can:

- recruit, for employment after graduating, students in the last two years in accredited universities, prioritizing the CN CFR SA employees family members (husband, wife, children);
- sign contracts with own employees following courses in state or private accredited universities.

In both situations, financing obligation contracts between the company and the beneficiary will be signed. In the first case, scholarships according to the criteria and allowance approved by the Board, can be granted, and in the second case the company will pay the scholarship taxes.

4. Hiring or promoting for management or administrative functions

Hiring or promoting for management or administrative functions (are stipulated in Railroad Personnel Appointing and Authorization Instruction) is being made, supplementary, by a commission, especially constituted for this, by an interview, apprising the capacity of exercising the function.

The interview is based on themes prepared and approved by the general department for coordination, or by the organizing regional branch, on a case by case basis, and contains one or more technical, economical, financial, juristic, social or organizational test, with each participant at a time. The activity during the interview takes place through oral questions addressed to the candidate by the commission members, so that, from answers, the candidate's point of view regarding the problems forming the objective of the interview will be revealed.

The interview takes place in the first semester of the year based on a program made and approved by the general department for coordination, or by the organizing regional branch, that will be transmitted to the participants at least 30 days before the interview.

The assessment of the functions exercising capacity for the provided personnel will be made through qualifiers "corresponding" or "not corresponding", that will be registered in the report written by the interviewing commission. An important aspect in establishing the objective is taking into account the recommendation made by the interviewed person's direct superior.

5. Conclusions

Tracking the personnel's number and structure, the professional re-conversion from redundant professions towards others with a longer training process, as well as supervising the retiring perspective represents the main aspects that contribute to maintaining an efficient personnel policy, summarised in:

- building up provisions regarding the necessity for personnel (numeric, qualitative, on specialization, qualification), that take into account the modifications occurred in the transport market and competition's conditions;
- recruiting and permanently appointing the personnel;
- selecting the personnel with promotion perspectives;
- procedures for evaluating the employees;
- establishing the needs for professional forming;
- elaborating the plan for employees professional training and perfecting.

In order to have according results following the effort made for correlating the number of personnel with the level of the labour conscription, it is necessary that company's employees are efficiently used.

The professional forming activity carried, so far, by the Human Resources Department aimed the providing of qualified workforce need, the professional re-conversion of redundant personnel, perfecting the professional training of a significant number of employees and elaborating specific regulations. At the same time, the main objectives of the activity regarding the professional forming consist of adopting strategies for attracting workforce towards the sectors with a chronic personnel deficiency, by: granting scholarships, paying the scholarship taxes, organizing actions to promote these domains of activity among the social categories fit for them, contacting decision factors in university teaching for an analysis of the ways to improve the bilateral relationships so that both parties will profit from, as well as professional forming of the personnel - qualification courses, perfecting programmes.

In the personnel policy in the 2011 -2012 period the following will be taken into account:

- Approaching modern techniques for building up previsions about the necessity for personnel for the company starting, from the analysis of the existing situation regarding unit's human resources, changes in market's and competition's conditions and planed work's productivity;
- Elaborating methods and techniques for selecting, appointing and integrating the unit's personnel that meet the highest exigencies in the matter;
- Using, for the lines, SCB, electricity departments, especially for activities that do not request a special qualification, a flexible rate setting scheme that permits the employment of personnel for a determined period of time (3-4 months), when there is an intense activity (especially during summertime);
- Using an employees evaluating system regarding the requirements and particularities of the jobs, the responsibilities, that will form the base of highlighting the human potential of the company and fixing the professional perspectives and employees promotion;
- Elaborating an improvement and qualifying system for the whole personnel generated the use of modern technology, by rising the qualification level, widening the area of qualification, earning new qualifications;
- Elaborating a financial co-interest system for the employees, materialized in the collective working contract, that motivates and stimulates them, amplifying the worker's belonging to the company sentiment when realizing certain economical parameters;
- A permanent knowledge of the employee's denunciations and claims and solving them, as much as possible, in order to prevent social conflicts and minimizing them through social dialog, personnel motivation, improving working conditions.
